Bring-your-own-shard (BYOS) describes a use case where you already have a sharded/partitioned database and an application capable of accessing it. The shards are already physically separated. Thus, you can easily move the workload to Aurora multi-master clusters without changing your schema design. The same simple migration path applies to multitenant databases, where each tenant uses a dedicated table, a set of tables, or an entire database.

You map shards or tenants to DB instances in a one-to-one or many-to-one fashion. Each DB instance handles one or more shards. The sharded design primarily applies to write operations. You can issue `SELECT` queries for any shard from any DB instance with equivalent performance.

Suppose you used a multi-master cluster for a sharded gaming application. You might distribute the work so that database updates are performed by specific DB instances, depending on the player's user name. Your application handles the logic of mapping each player to the appropriate DB instance and connecting to the endpoint for that instance. Each DB instance can handle write operations for many different shards. You can submit queries to any DB instance, because conflicts can only arise during write operations. You might designate one DB instance to perform all `SELECT` queries to minimize the overhead on the DB instances that perform write operations.

Suppose that as time goes on, one of the shards becomes much more active. To rebalance the workload, you can switch which DB instance is responsible for that shard. In a non-Aurora system, you might have to physically move the data to a different server. With an Aurora multi-master cluster, you can reshuffle

like this by directing all write operations for the shard to some other DB instance that has unused compute capacity. The Aurora shared storage model avoids the need to physically reorganize the data.

## Using a multi-master cluster without sharding

If your schema design doesn't subdivide the data into physically separate containers such as databases, tables, or partitions, you can still divide write operations such as DML statements among the DB instances in a multi-master cluster.

You might see some performance overhead, and your application might have to deal with occasional transaction rollbacks when write conflicts are treated as deadlock conditions. Write conflicts are more likely during write operations for small tables. If a table contains few data pages, rows from different parts of the primary key range might be in the same data page. This overlap might lead to write conflicts if those rows are changed simultaneously by different DB instances.

You should also minimize the number of secondary indexes in this case. When you make a change to indexed columns in a table, Aurora makes corresponding changes in the associated secondary indexes. A change to an index could cause a write conflict because the order and grouping of rows is different between a secondary index and the associated table.

Because you might still experience some write conflicts when using this technique, Amazon recommends using a different approach if practical. See if you can use an alternative database design that subdivides the data into different schema objects.

## Using a multi-master cluster as an active standby

An *active standby* is a DB instance that is kept synchronized with another DB instance, and is ready to take over for it very quickly. This configuration helps with high availability in situations where a single DB instance can handle the full workload.

You can use multi-master clusters in an active standby configuration by directing all traffic, both read/write and read-only, to a single DB instance. If that DB instance becomes unavailable, your application must detect the problem and switch all connections to a different DB instance. In this case, Aurora doesn't perform any failover because the other DB instance is already available to accept read/write connections. By only writing to a single DB instance at any one time, you avoid write conflicts. Thus, you don't need to have a sharded database schema to use multi-master clusters in this way.

### Tip

If your application can tolerate a brief pause, you can wait several seconds after a DB instance becomes unavailable before redirecting write traffic to another instance. When an instance becomes unavailable because of a restart, it becomes available again after approximately 10–20 seconds. If the instance can't restart quickly, Aurora might initiate recovery for that instance. When an instance is shut down, it performs some additional cleanup activities as part of the shutdown. If you begin writing to a different instance while the instance is restarting, undergoing recovery, or being shut down, you can encounter write conflicts. The conflicts can occur between SQL statements on the new instance, and recovery operations such as rollback and purge on the instance that was restarted or shut down.

# Integrating Amazon Aurora MySQL with other AWS services

Amazon Aurora MySQL integrates with other AWS services so that you can extend your Aurora MySQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora MySQL DB cluster can use AWS services to do the following:

- Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. For more information, see [Invoking a Lambda function from an Amazon Aurora MySQL DB cluster \(p. 917\)](#).
- Load data from text or XML files stored in an Amazon Simple Storage Service (Amazon S3) bucket into your DB cluster using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` command. For more information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket \(p. 903\)](#).
- Save data to text files stored in an Amazon S3 bucket from your DB cluster using the `SELECT INTO OUTFILE S3` command. For more information, see [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket \(p. 911\)](#).
- Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see [Using Amazon Aurora Auto Scaling with Aurora replicas \(p. 305\)](#).
- Perform sentiment analysis with Amazon Comprehend, or a wide variety of machine learning algorithms with SageMaker. For more information, see [Using machine learning \(ML\) capabilities with Amazon Aurora \(p. 320\)](#).

Aurora secures the ability to access other AWS services by using AWS Identity and Access Management (IAM). You grant permission to access other AWS services by creating an IAM role with the necessary permissions, and then associating the role with your DB cluster. For details and instructions on how to permit your Aurora MySQL DB cluster to access other AWS services on your behalf, see [Authorizing Amazon Aurora MySQL to access other AWS services on your behalf \(p. 891\)](#).

## Authorizing Amazon Aurora MySQL to access other AWS services on your behalf

### Note

Integration with other AWS services is available for Amazon Aurora MySQL version 1.8 and later. Some integration features are only available for later versions of Aurora MySQL. For more information on Aurora versions, see [Database engine updates for Amazon Aurora MySQL \(p. 990\)](#).

For your Aurora MySQL DB cluster to access other services on your behalf, create and configure an AWS Identity and Access Management (IAM) role. This role authorizes database users in your DB cluster to access other AWS services. For more information, see [Setting up IAM roles to access AWS services \(p. 892\)](#).

You must also configure your Aurora DB cluster to allow outbound connections to the target AWS service. For more information, see [Enabling network communication from Amazon Aurora MySQL to other AWS services \(p. 902\)](#).

If you do so, your database users can perform these actions using other AWS services:

- Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. Or, asynchronously invoke an AWS Lambda function using the `mysql.lambda_async` procedure. For more information, see [Invoking a Lambda function with an Aurora MySQL native function \(p. 918\)](#).
- Load data from text or XML files stored in an Amazon S3 bucket into your DB cluster by using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement. For more information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket \(p. 903\)](#).
- Save data from your DB cluster into text files stored in an Amazon S3 bucket by using the `SELECT INTO OUTFILE S3` statement. For more information, see [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket \(p. 911\)](#).
- Export log data to Amazon CloudWatch Logs MySQL. For more information, see [Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs \(p. 924\)](#).

- Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see [Using Amazon Aurora Auto Scaling with Aurora replicas \(p. 305\)](#).

## Setting up IAM roles to access AWS services

To permit your Aurora DB cluster to access another AWS service, do the following:

1. Create an IAM policy that grants permission to the AWS service. For more information, see:
  - [Creating an IAM policy to access Amazon S3 resources \(p. 892\)](#)
  - [Creating an IAM policy to access AWS Lambda resources \(p. 894\)](#)
  - [Creating an IAM policy to access CloudWatch Logs resources \(p. 895\)](#)
  - [Creating an IAM policy to access AWS KMS resources \(p. 896\)](#)
2. Create an IAM role and attach the policy that you created. For more information, see [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#).
3. Associate that IAM role with your Aurora DB cluster. For more information, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster \(p. 898\)](#).

### Creating an IAM policy to access Amazon S3 resources

Aurora can access Amazon S3 resources to either load data to or save data from an Aurora DB cluster. However, you must first create an IAM policy that provides the bucket and object permissions that allow Aurora to access Amazon S3.

The following table lists the Aurora features that can access an Amazon S3 bucket on your behalf, and the minimum required bucket and object permissions required by each feature.

Feature	Bucket permissions	Object permissions
LOAD DATA FROM S3	ListBucket	GetObject GetObjectVersion
LOAD XML FROM S3	ListBucket	GetObject GetObjectVersion
SELECT INTO OUTFILE S3	ListBucket	AbortMultipartUpload DeleteObject GetObject ListMultipartUploadParts PutObject

The following policy adds the permissions that might be required by Aurora to access an Amazon S3 bucket on your behalf.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowAuroraToExampleBucket",  
            "Effect": "Allow",  
            "Action": "s3:GetObject",  
            "Resource": "arn:aws:s3:::examplebucket/*"  
        }  
    ]  
}
```

```
        "Effect": "Allow",
        "Action": [
            "s3:PutObject",
            "s3:GetObject",
            "s3:AbortMultipartUpload",
            "s3>ListBucket",
            "s3>DeleteObject",
            "s3:GetObjectVersion",
            "s3>ListMultipartUploadParts"
        ],
        "Resource": [
            "arn:aws:s3::::example-bucket/*",
            "arn:aws:s3::::example-bucket"
        ]
    }
}
```

#### Note

Make sure to include both entries for the `Resource` value. Aurora needs the permissions on both the bucket itself and all the objects inside the bucket.

Based on your use case, you might not need to add all of the permissions in the sample policy. Also, other permissions might be required. For example, if your Amazon S3 bucket is encrypted, you need to add `kms:Decrypt` permissions.

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access an Amazon S3 bucket on your behalf. To allow Aurora to access all of your Amazon S3 buckets, you can skip these steps and use either the `AmazonS3ReadOnlyAccess` or `AmazonS3FullAccess` predefined IAM policy instead of creating your own.

#### To create an IAM policy to grant access to your Amazon S3 resources

1. Open the [IAM Management Console](#).
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **S3**.
5. For **Actions**, choose **Expand all**, and then choose the bucket permissions and object permissions needed for the IAM policy.

Object permissions are permissions for object operations in Amazon S3, and need to be granted for objects in a bucket, not the bucket itself. For more information about permissions for object operations in Amazon S3, see [Permissions for object operations](#).

6. Choose **Resources**, and choose **Add ARN for bucket**.
7. In the **Add ARN(s)** dialog box, provide the details about your resource, and choose **Add**.

Specify the Amazon S3 bucket to allow access to. For instance, if you want to allow Aurora to access the Amazon S3 bucket named `example-bucket`, then set the Amazon Resource Name (ARN) value to `arn:aws:s3::::example-bucket`.

8. If the **object** resource is listed, choose **Add ARN for object**.
9. In the **Add ARN(s)** dialog box, provide the details about your resource.

For the Amazon S3 bucket, specify the Amazon S3 bucket to allow access to. For the object, you can choose **Any** to grant permissions to any object in the bucket.

#### Note

You can set **Amazon Resource Name (ARN)** to a more specific ARN value in order to allow Aurora to access only specific files or folders in an Amazon S3 bucket. For more information

about how to define an access policy for Amazon S3, see [Managing access permissions to your Amazon S3 resources](#).

10. (Optional) Choose **Add ARN for bucket** to add another Amazon S3 bucket to the policy, and repeat the previous steps for the bucket.

**Note**

You can repeat this to add corresponding bucket permission statements to your policy for each Amazon S3 bucket that you want Aurora to access. Optionally, you can also grant access to all buckets and objects in Amazon S3.

11. Choose **Review policy**.
12. For **Name**, enter a name for your IAM policy, for example `AllowAuroraToExampleBucket`. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.
13. Choose **Create policy**.
14. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#).

## Creating an IAM policy to access AWS Lambda resources

You can create an IAM policy that provides the minimum required permissions for Aurora to invoke an AWS Lambda function on your behalf.

The following policy adds the permissions required by Aurora to invoke an AWS Lambda function on your behalf.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowAuroraToExampleFunction",  
            "Effect": "Allow",  
            "Action": "lambda:InvokeFunction",  
            "Resource":  
                "arn:aws:lambda:<region>:<123456789012>:function:<example_function>"  
        }  
    ]  
}
```

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to invoke an AWS Lambda function on your behalf. To allow Aurora to invoke all of your AWS Lambda functions, you can skip these steps and use the predefined `AWSLambdaRole` policy instead of creating your own.

### To create an IAM policy to grant invoke to your AWS Lambda functions

1. Open the [IAM console](#).
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **Lambda**.
5. For **Actions**, choose **Expand all**, and then choose the AWS Lambda permissions needed for the IAM policy.

Ensure that `InvokeFunction` is selected. It is the minimum required permission to enable Amazon Aurora to invoke an AWS Lambda function.

6. Choose **Resources** and choose **Add ARN for function**.

7. In the **Add ARN(s)** dialog box, provide the details about your resource.

Specify the Lambda function to allow access to. For instance, if you want to allow Aurora to access a Lambda function named `example_function`, then set the ARN value to `arn:aws:lambda:::function:example_function`.

For more information on how to define an access policy for AWS Lambda, see [Authentication and access control for AWS Lambda](#).

8. Optionally, choose **Add additional permissions** to add another AWS Lambda function to the policy, and repeat the previous steps for the function.

**Note**

You can repeat this to add corresponding function permission statements to your policy for each AWS Lambda function that you want Aurora to access.

9. Choose **Review policy**.

10. Set **Name** to a name for your IAM policy, for example `AllowAuroraToExampleFunction`. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.

11. Choose **Create policy**.

12. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#).

## Creating an IAM policy to access CloudWatch Logs resources

Aurora can access CloudWatch Logs to export audit log data from an Aurora DB cluster. However, you must first create an IAM policy that provides the log group and log stream permissions that allow Aurora to access CloudWatch Logs.

The following policy adds the permissions required by Aurora to access Amazon CloudWatch Logs on your behalf, and the minimum required permissions to create log groups and export data.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogEvents",  
            "Effect": "Allow",  
            "Action": [  
                "logs:GetLogEvents",  
                "logs:PutLogEvents"  
            ],  
            "Resource": "arn:aws:logs:*:log-group:/aws/rds/*:log-stream:*"  
        },  
        {  
            "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogGroupsAndStreams",  
            "Effect": "Allow",  
            "Action": [  
                "logs>CreateLogStream",  
                "logs:DescribeLogStreams",  
                "logs:PutRetentionPolicy",  
                "logs>CreateLogGroup"  
            ],  
            "Resource": "arn:aws:logs:*:log-group:/aws/rds/*"  
        }  
    ]  
}
```

You can modify the ARNs in the policy to restrict access to a specific AWS Region and account.

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access CloudWatch Logs on your behalf. To allow Aurora full access to CloudWatch Logs, you can skip these steps and use the `CloudWatchLogsFullAccess` predefined IAM policy instead of creating your own. For more information, see [Using identity-based policies \(IAM policies\) for CloudWatch Logs](#) in the *Amazon CloudWatch User Guide*.

### To create an IAM policy to grant access to your CloudWatch Logs resources

1. Open the [IAM console](#).
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **CloudWatch Logs**.
5. For **Actions**, choose **Expand all** (on the right), and then choose the Amazon CloudWatch Logs permissions needed for the IAM policy.

Ensure that the following permissions are selected:

- `CreateLogGroup`
  - `CreateLogStream`
  - `DescribeLogStreams`
  - `GetLogEvents`
  - `PutLogEvents`
  - `PutRetentionPolicy`
6. Choose **Resources** and choose **Add ARN for log-group**.
  7. In the **Add ARN(s)** dialog box, enter the following values:
    - **Region** – An AWS Region or \*
    - **Account** – An account number or \*
    - **Log Group Name** – `/aws/rds/*`
  8. In the **Add ARN(s)** dialog box, choose **Add**.
  9. Choose **Add ARN for log-stream**.
  10. In the **Add ARN(s)** dialog box, enter the following values:
    - **Region** – An AWS Region or \*
    - **Account** – An account number or \*
    - **Log Group Name** – `/aws/rds/*`
    - **Log Stream Name** – \*
  11. In the **Add ARN(s)** dialog box, choose **Add**.
  12. Choose **Review policy**.
  13. Set **Name** to a name for your IAM policy, for example `AmazonRDSCloudWatchLogs`. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.
  14. Choose **Create policy**.
  15. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#).

### Creating an IAM policy to access AWS KMS resources

Aurora can access the AWS KMS keys used for encrypting their database backups. However, you must first create an IAM policy that provides the permissions that allow Aurora to access KMS keys.

The following policy adds the permissions required by Aurora to access KMS keys on your behalf.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "kms:Decrypt"  
            ],  
            "Resource": "arn:aws:kms:<region>:<123456789012>:key/<key-ID>"  
        }  
    ]  
}
```

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access KMS keys on your behalf.

### To create an IAM policy to grant access to your KMS keys

1. Open the [IAM console](#).
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **KMS**.
5. For **Actions**, choose **Write**, and then choose **Decrypt**.
6. Choose **Resources**, and choose **Add ARN**.
7. In the **Add ARN(s)** dialog box, enter the following values:
  - **Region** – Type the AWS Region, such as `us-west-2`.
  - **Account** – Type the user account number.
  - **Log Stream Name** – Type the KMS key identifier.
8. In the **Add ARN(s)** dialog box, choose **Add**
9. Choose **Review policy**.
10. Set **Name** to a name for your IAM policy, for example `AmazonRDSKMSKey`. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.
11. Choose **Create policy**.
12. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#).

### Creating an IAM role to allow Amazon Aurora to access AWS services

After creating an IAM policy to allow Aurora to access AWS resources, you must create an IAM role and attach the IAM policy to the new IAM role.

To create an IAM role to permit your Amazon RDS cluster to communicate with other AWS services on your behalf, take the following steps.

### To create an IAM role to allow Amazon RDS to access AWS services

1. Open the [IAM console](#).
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Under **AWS service**, choose **RDS**.
5. Under **Select your use case**, choose **RDS – Add Role to Database**.
6. Choose **Next**.

7. On the **Permissions policies** page, enter the name of your policy in the **Search** field.
8. When it appears in the list, select the policy that you defined earlier using the instructions in one of the following sections:
  - [Creating an IAM policy to access Amazon S3 resources \(p. 892\)](#)
  - [Creating an IAM policy to access AWS Lambda resources \(p. 894\)](#)
  - [Creating an IAM policy to access CloudWatch Logs resources \(p. 895\)](#)
  - [Creating an IAM policy to access AWS KMS resources \(p. 896\)](#)
9. Choose **Next**.
10. In **Role name**, enter a name for your IAM role, for example `RDSLoadFromS3`. You can also add an optional **Description** value.
11. Choose **Create Role**.
12. Complete the steps in [Associating an IAM role with an Amazon Aurora MySQL DB cluster \(p. 898\)](#).

## Associating an IAM role with an Amazon Aurora MySQL DB cluster

To permit database users in an Amazon Aurora DB cluster to access other AWS services, you associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#) with that DB cluster.

### Note

You can't associate an IAM role with an Aurora Serverless v1 DB cluster. For more information, see [Using Amazon Aurora Serverless v1 \(p. 1543\)](#).

You can associate an IAM role with an Aurora Serverless v2 DB cluster.

To associate an IAM role with a DB cluster you do two things:

- Add the role to the list of associated roles for a DB cluster by using the RDS console, the `add-role-to-db-cluster` AWS CLI command, or the `AddRoleToDBCluster` RDS API operation.

You can add a maximum of five IAM roles for each Aurora DB cluster.

- Set the cluster-level parameter for the related AWS service to the ARN for the associated IAM role.

The following table describes the cluster-level parameter names for the IAM roles used to access other AWS services.

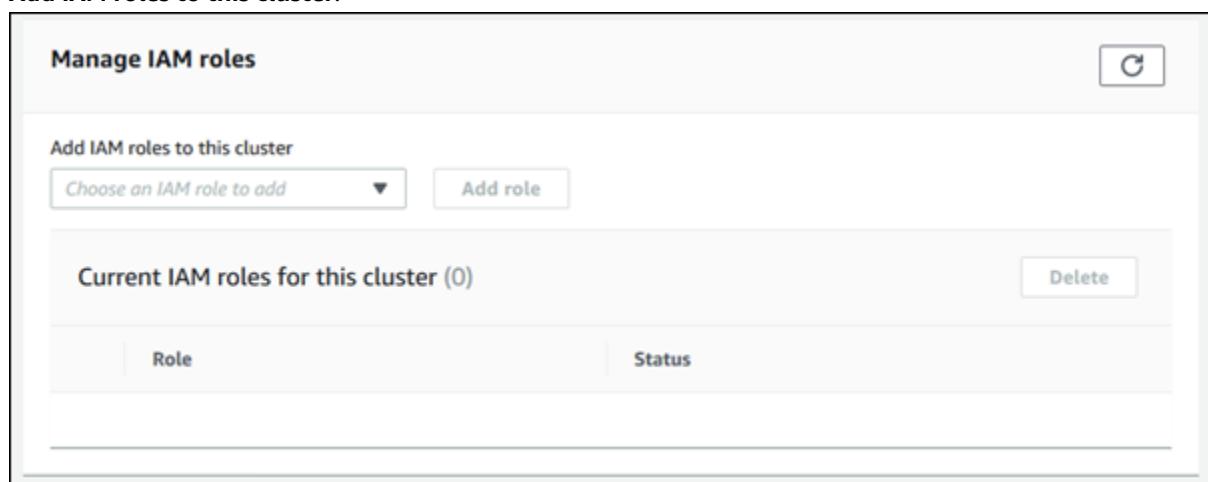

Cluster-level parameter	Description
<code>aws_default_lambda_role</code>	Used when invoking a Lambda function from your DB cluster.
<code>aws_default_logs_role</code>	This parameter is no longer required for exporting log data from your DB cluster to Amazon CloudWatch Logs. Aurora MySQL now uses a service-linked role for the required permissions. For more information about service-linked roles, see <a href="#">Using service-linked roles for Amazon Aurora (p. 1724)</a> .
<code>aws_default_s3_role</code>	Used when invoking the <code>LOAD DATA FROM S3</code> , <code>LOAD XML FROM S3</code> , or <code>SELECT INTO OUTFILE S3</code> statement from your DB cluster.  The IAM role specified in this parameter is used if an IAM role isn't specified

Cluster-level parameter	Description	
	<p>for <code>aurora_load_from_s3_role</code> or <code>aurora_select_into_s3_role</code> for the appropriate statement.</p> <p>For Aurora MySQL version 3, the IAM role specified for this parameter is always used.</p>	
<code>aurora_load_from_s3</code>	<p><del>Used</del> when invoking the <code>LOAD DATA FROM S3</code> or <code>LOAD XML FROM S3</code> statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in <code>aws_default_s3_role</code> is used.</p> <p>For Aurora MySQL version 3, this parameter isn't available.</p>	
<code>aurora_select_into_s3</code>	<p><del>Used</del> when invoking the <code>SELECT INTO OUTFILE S3</code> statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in <code>aws_default_s3_role</code> is used.</p> <p>For Aurora MySQL version 3, this parameter isn't available.</p>	

To associate an IAM role to permit your Amazon RDS cluster to communicate with other AWS services on your behalf, take the following steps.

#### To associate an IAM role with an Aurora DB cluster using the console

1. Open the RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases**.
3. Choose the name of the Aurora DB cluster that you want to associate an IAM role with to show its details.
4. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this cluster**.

5. Choose **Add role**.

6. (Optional) To stop associating an IAM role with a DB cluster and remove the related permission, choose the role and choose **Delete**.
7. In the RDS console, choose **Parameter groups** in the navigation pane.
8. If you are already using a custom DB parameter group, you can select that group to use instead of creating a new DB cluster parameter group. If you are using the default DB cluster parameter group, create a new DB cluster parameter group, as described in the following steps:
  - a. Choose **Create parameter group**.
  - b. For **Parameter group family**, choose `aurora-mysql8.0` for an Aurora MySQL 8.0-compatible DB cluster, choose `aurora-mysql5.7` for an Aurora MySQL 5.7-compatible DB cluster, or choose `aurora5.6` for an Aurora MySQL 5.6-compatible DB cluster.
  - c. For **Type**, choose **DB Cluster Parameter Group**.
  - d. For **Group name**, type the name of your new DB cluster parameter group.
  - e. For **Description**, type a description for your new DB cluster parameter group.

The screenshot shows the 'Create parameter group' dialog box. It has a title 'Create parameter group' at the top. Below it is a section titled 'Parameter group details' with the sub-instruction: 'To create a parameter group, select a parameter group family, then name and describe your parameter group'. There are four input fields: 'Parameter group family' (dropdown menu showing 'aurora5.6'), 'Type' (dropdown menu showing 'DB Cluster Parameter Group'), 'Group name' (text input field containing 'AllowAWSAccess'), and 'Description' (text input field containing 'Allow access to S3'). At the bottom right are 'Cancel' and 'Create' buttons.

- f. Choose **Create**.
9. On the **Parameter groups** page, select your DB cluster parameter group and choose **Edit** for **Parameter group actions**.
10. Set the appropriate cluster-level parameters to the related IAM role ARN values. For example, you can set just the `aws_default_s3_role` parameter to `arn:aws:iam::123456789012:role/AllowAuroraS3Role`.
11. Choose **Save changes**.
12. To change the DB cluster parameter group for your DB cluster, complete the following steps:
  - a. Choose **Databases**, and then choose your Aurora DB cluster.
  - b. Choose **Modify**.
  - c. Scroll to **Database options** and set **DB cluster parameter group** to the DB cluster parameter group.
  - d. Choose **Continue**.

- e. Verify your changes and then choose **Apply immediately**.
- f. Choose **Modify cluster**.
- g. Choose **Databases**, and then choose the primary instance for your DB cluster.
- h. For **Actions**, choose **Reboot**.

When the instance has rebooted, your IAM role is associated with your DB cluster.

For more information about cluster parameter groups, see [Aurora MySQL configuration parameters \(p. 949\)](#).

### To associate an IAM role with a DB cluster by using the AWS CLI

1. Call the `add-role-to-db-cluster` command from the AWS CLI to add the ARNs for your IAM roles to the DB cluster, as shown following.

```
PROMPT> aws rds add-role-to-db-cluster --db-cluster-identifier my-cluster --role-arn arn:aws:iam::123456789012:role/AllowAuroraS3Role
PROMPT> aws rds add-role-to-db-cluster --db-cluster-identifier my-cluster --role-arn arn:aws:iam::123456789012:role/AllowAuroraLambdaRole
```

2. If you are using the default DB cluster parameter group, create a new DB cluster parameter group. If you are already using a custom DB parameter group, you can use that group instead of creating a new DB cluster parameter group.

To create a new DB cluster parameter group, call the `create-db-cluster-parameter-group` command from the AWS CLI, as shown following.

```
PROMPT> aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccess \
    --db-parameter-group-family aurora5.6 --description "Allow access to Amazon S3 and
    AWS Lambda"
```

For an Aurora MySQL 5.7-compatible DB cluster, specify `aurora-mysql5.7` for `--db-parameter-group-family`. For an Aurora MySQL 8.0-compatible DB cluster, specify `aurora-mysql8.0` for `--db-parameter-group-family`.

3. Set the appropriate cluster-level parameter or parameters and the related IAM role ARN values in your DB cluster parameter group, as shown following.

```
PROMPT> aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccess \
    --parameters
    "ParameterName=aws_default_s3_role,ParameterValue=arn:aws:iam::123456789012:role/
    AllowAuroraS3Role,method=pending-reboot" \
    --parameters
    "ParameterName=aws_default_lambda_role,ParameterValue=arn:aws:iam::123456789012:role/
    AllowAuroraLambdaRole,method=pending-reboot"
```

4. Modify the DB cluster to use the new DB cluster parameter group and then reboot the cluster, as shown following.

```
PROMPT> aws rds modify-db-cluster --db-cluster-identifier my-cluster --db-cluster-
parameter-group-name AllowAWSAccess
PROMPT> aws rds reboot-db-instance --db-instance-identifier my-cluster-primary
```

When the instance has rebooted, your IAM roles are associated with your DB cluster.

For more information about cluster parameter groups, see [Aurora MySQL configuration parameters \(p. 949\)](#).

## Enabling network communication from Amazon Aurora MySQL to other AWS services

To use certain other AWS services with Amazon Aurora, the network configuration of your Aurora DB cluster must allow outbound connections to endpoints for those services. The following operations require this network configuration.

- Invoking AWS Lambda functions. To learn about this feature, see [Invoking a Lambda function with an Aurora MySQL native function \(p. 918\)](#).
- Accessing files from Amazon S3. To learn about this feature, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket \(p. 903\)](#) and [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket \(p. 911\)](#).
- Accessing AWS KMS endpoints. AWS KMS access is required to use database activity streams with Aurora MySQL. To learn about this feature, see [Monitoring Amazon Aurora with Database Activity Streams \(p. 619\)](#).
- Accessing SageMaker endpoints. SageMaker access is required to use SageMaker machine learning with Aurora MySQL. To learn about this feature, see [Using machine learning \(ML\) with Aurora MySQL \(p. 927\)](#).

Aurora returns the following error messages if it can't connect to a service endpoint.

```
ERROR 1871 (HY000): S3 API returned error: Network Connection
```

```
ERROR 1873 (HY000): Lambda API returned error: Network Connection. Unable to connect to endpoint
```

```
ERROR 1815 (HY000): Internal error: Unable to initialize S3Stream
```

For database activity streams using Aurora MySQL, the activity stream stops functioning if the DB cluster can't access the AWS KMS endpoint. Aurora notifies you about this issue using RDS Events.

If you encounter these messages while using the corresponding AWS services, check if your Aurora DB cluster is public or private. If your Aurora DB cluster is private, you must configure it to enable connections.

For an Aurora DB cluster to be public, it must be marked as publicly accessible. If you look at the details for the DB cluster in the AWS Management Console, **Publicly Accessible** is **Yes** if this is the case. The DB cluster must also be in an Amazon VPC public subnet. For more information about publicly accessible DB instances, see [Working with a DB cluster in a VPC \(p. 1729\)](#). For more information about public Amazon VPC subnets, see [Your VPC and subnets](#).

If your Aurora DB cluster isn't publicly accessible and in a VPC public subnet, it is private. You might have a DB cluster that is private and want to use one of the features that requires this network configuration. If so, configure the cluster so that it can connect to Internet addresses through Network Address Translation (NAT). As an alternative for Amazon S3, Amazon SageMaker, and AWS Lambda, you can instead configure the VPC to have a VPC endpoint for the other service associated with the DB cluster's route table. For more information about configuring NAT in your VPC, see [NAT gateways](#). For more information about configuring VPC endpoints, see [VPC endpoints](#).

You might also have to open the ephemeral ports for your network access control lists (ACLs) in the outbound rules for your VPC security group. For more information on ephemeral ports for network ACLs, see [Ephemeral ports](#) in the *Amazon Virtual Private Cloud User Guide*.

- [Managing an Amazon Aurora DB cluster \(p. 243\)](#)

# Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket

You can use the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement to load data from files stored in an Amazon S3 bucket.

If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can't load data from a bucket that is encrypted with a customer managed key.

### Note

Loading data into a table from text files in an Amazon S3 bucket is available for Amazon Aurora MySQL version 1.8 and later. For more information about Aurora MySQL versions, see [Database engine updates for Amazon Aurora MySQL \(p. 990\)](#).

This feature isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

## Giving Aurora access to Amazon S3

Before you can load data from an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.

### To give Aurora MySQL access to Amazon S3

1. Create an AWS Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see [Creating an IAM policy to access Amazon S3 resources \(p. 892\)](#).
2. Create an IAM role, and attach the IAM policy you created in [Creating an IAM policy to access Amazon S3 resources \(p. 892\)](#) to the new IAM role. For instructions, see [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#).
3. Make sure the DB cluster is using a custom DB cluster parameter group.

For more information about creating a custom DB cluster parameter group, see [Creating a DB cluster parameter group \(p. 219\)](#).

4. For Aurora MySQL version 1 or 2, set either the `aurora_load_from_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_load_from_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.

For Aurora MySQL version 3, use `aws_default_s3_role`.

If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database. Although only the primary cluster in an Aurora global database can load data, another cluster might be promoted by the failover mechanism and become the primary cluster.

For more information about DB cluster parameters, see [Amazon Aurora DB cluster and DB instance parameters \(p. 217\)](#).

5. To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#) with the DB cluster. For an Aurora global database, associate the role with each Aurora cluster in the global database. For information about associating an IAM role with a DB cluster, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster \(p. 898\)](#).
6. Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services \(p. 902\)](#).

For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

## Granting privileges to load data in Amazon Aurora MySQL

The database user that issues the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement must have a specific role or privilege to issue either statement. In Aurora MySQL version 3, you grant the `AWS_LOAD_S3_ACCESS` role. In Aurora MySQL version 1 or 2, you grant the `LOAD FROM S3` privilege. The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:

```
GRANT AWS_LOAD_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

### Tip

When you use the role technique in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in [Role-based privilege model \(p. 664\)](#). You can also find more details in [Using Roles in the MySQL Reference Manual](#).

This only applies to the current active session. When you reconnect, you have to run the `SET ROLE` statement again to grant privileges. For more information, see [SET ROLE statement](#) in the [MySQL Reference Manual](#).

You can also use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you don't have to call the `SET ROLE` statement explicitly to activate a role. For more information, see [activate\\_all\\_roles\\_on\\_login](#) in the [MySQL Reference Manual](#).

Use the following statement for Aurora MySQL version 1 or 2:

```
GRANT LOAD FROM S3 ON *.* TO 'user'@'domain-or-ip-address'
```

The `AWS_LOAD_S3_ACCESS` role and `LOAD FROM S3` privilege are specific to Amazon Aurora and are not available for MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora DB cluster as the replication master and a MySQL database as the replication client, then the `GRANT` statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on an RDS for MySQL DB instance, use the `mysql_rds_skip_repl_error` procedure. To skip the error on an external MySQL database, use the `SET GLOBAL sql_slave_skip_counter` statement (Aurora MySQL version 1 and 2) or `SET GLOBAL sql_replica_skip_counter` statement (Aurora MySQL version 3).

## Specifying a path to an Amazon S3 bucket

The syntax for specifying a path to files stored on an Amazon S3 bucket is as follows.

```
s3-region://bucket-name/file-name-or-prefix
```

The path includes the following values:

- **region** (optional) – The AWS Region that contains the Amazon S3 bucket to load from. This value is optional. If you don't specify a **region** value, then Aurora loads your file from Amazon S3 in the same region as your DB cluster.
- **bucket-name** – The name of the Amazon S3 bucket that contains the data to load. Object prefixes that identify a virtual folder path are supported.
- **file-name-or-prefix** – The name of the Amazon S3 text file or XML file, or a prefix that identifies one or more text or XML files to load. You can also specify a manifest file that identifies one or more text files to load. For more information about using a manifest file to load text files from Amazon S3, see [Using a manifest to specify data files to load \(p. 906\)](#).

## LOAD DATA FROM S3

You can use the `LOAD DATA FROM S3` statement to load data from any text file format that is supported by the MySQL `LOAD DATA INFILE` statement, such as text data that is comma-delimited. Compressed files are not supported.

### Syntax

```
LOAD DATA FROM S3 [FILE | PREFIX | MANIFEST] 'S3-URI'  
    [REPLACE | IGNORE]  
    INTO TABLE tbl_name  
    [PARTITION (partition_name,...)]  
    [CHARACTER SET charset_name]  
    [{FIELDS | COLUMNS}  
        [TERMINATED BY 'string']  
        [[OPTIONALLY] ENCLOSED BY 'char']  
        [ESCAPED BY 'char']  
    ]  
    [LINES  
        [STARTING BY 'string']  
        [TERMINATED BY 'string']  
    ]  
    [IGNORE number {LINES | ROWS}]  
    [(col_name_or_user_var,...)]  
    [SET col_name = expr,...]
```

### Parameters

Following, you can find a list of the required and optional parameters used by the `LOAD DATA FROM S3` statement. You can find more details about some of these parameters in [LOAD DATA INFILE syntax](#) in the MySQL documentation.

- **FILE | PREFIX | MANIFEST** – Identifies whether to load the data from a single file, from all files that match a given prefix, or from all files in a specified manifest. **FILE** is the default.
- **S3-URI** – Specifies the URI for a text or manifest file to load, or an Amazon S3 prefix to use. Specify the URI using the syntax described in [Specifying a path to an Amazon S3 bucket \(p. 904\)](#).
- **REPLACE | IGNORE** – Determines what action to take if an input row as the same unique key values as an existing row in the database table.
  - Specify **REPLACE** if you want the input row to replace the existing row in the table.
  - Specify **IGNORE** if you want to discard the input row.
- **INTO TABLE** – Identifies the name of the database table to load the input rows into.
- **PARTITION** – Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.

- **CHARACTER SET** – Identifies the character set of the data in the input file.
- **FIELDS | COLUMNS** – Identifies how the fields or columns in the input file are delimited. Fields are tab-delimited by default.
- **LINES** – Identifies how the lines in the input file are delimited. Lines are delimited by a newline character ('\n') by default.
- **IGNORE *number* LINES | ROWS** – Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use IGNORE 1 LINES to skip over an initial header line containing column names, or IGNORE 2 ROWS to skip over the first two rows of data in the input file. If you also use PREFIX, IGNORE skips a certain number of lines or rows at the start of the first input file.
- **col\_name\_or\_user\_var, ...** – Specifies a comma-separated list of one or more column names or user variables that identify which columns to load by name. The name of a user variable used for this purpose must match the name of an element from the text file, prefixed with @. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of `table1`, and sets the value of the `table_column2` column in `table1` to the input value of the second column divided by 100.

```
LOAD DATA FROM S3 's3://mybucket/data.txt'
    INTO TABLE table1
        (column1, @var1)
    SET table_column2 = @var1/100;
```

- **SET** – Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of `table1` to the values in the first two columns from the input file, and then sets the value of the `column3` in `table1` to the current time stamp.

```
LOAD DATA FROM S3 's3://mybucket/data.txt'
    INTO TABLE table1
        (column1, column2)
    SET column3 = CURRENT_TIMESTAMP;
```

You can use subqueries in the right side of `SET` assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you cannot use a subquery to select from the table that is being loaded.

You cannot use the `LOCAL` keyword of the `LOAD DATA FROM S3` statement if you are loading data from an Amazon S3 bucket.

## Using a manifest to specify data files to load

You can use the `LOAD DATA FROM S3` statement with the `MANIFEST` keyword to specify a manifest file in JSON format that lists the text files to be loaded into a table in your DB cluster. You must be using Aurora 1.11 or greater to use the `MANIFEST` keyword with the `LOAD DATA FROM S3` statement.

The following JSON schema describes the format and content of a manifest file.

```
{
    "$schema": "http://json-schema.org/draft-04/schema#",
    "additionalProperties": false,
    "definitions": {},
    "id": "Aurora_LoadFromS3_Manifest",
    "properties": {
        "entries": {
```

```

    "additionalItems": false,
    "id": "/properties/entries",
    "items": {
        "additionalProperties": false,
        "id": "/properties/entries/items",
        "properties": {
            "mandatory": {
                "default": "false"
                "id": "/properties/entries/items/properties/mandatory",
                "type": "boolean"
            },
            "url": {
                "id": "/properties/entries/items/properties/url",
                "maxLength": 1024,
                "minLength": 1,
                "type": "string"
            }
        },
        "required": [
            "url"
        ],
        "type": "object"
    },
    "type": "array",
    "uniqueItems": true
},
"required": [
    "entries"
],
"type": "object"
}
}

```

Each `url` in the manifest must specify a URL with the bucket name and full object path for the file, not just a prefix. You can use a manifest to load files from different buckets, different regions, or files that do not share the same prefix. If a region is not specified in the URL, the region of the target Aurora DB cluster is used. The following example shows a manifest file that loads four files from different buckets.

```

{
  "entries": [
    {
      "url": "s3://aurora-bucket/2013-10-04-customerdata",
      "mandatory": true
    },
    {
      "url": "s3-us-west-2://aurora-bucket-usw2/2013-10-05-customerdata",
      "mandatory": true
    },
    {
      "url": "s3://aurora-bucket/2013-10-04-customerdata",
      "mandatory": false
    },
    {
      "url": "s3://aurora-bucket/2013-10-05-customerdata"
    }
  ]
}

```

The optional `mandatory` flag specifies whether `LOAD DATA FROM S3` should return an error if the file is not found. The `mandatory` flag defaults to `false`. Regardless of how `mandatory` is set, `LOAD DATA FROM S3` terminates if no files are found.

Manifest files can have any extension. The following example runs the `LOAD DATA FROM S3` statement with the manifest in the previous example, which is named `customer.manifest`.

```
LOAD DATA FROM S3 MANIFEST 's3-us-west-2://aurora-bucket/customer.manifest'
INTO TABLE CUSTOMER
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
(ID, FIRSTNAME, LASTNAME, EMAIL);
```

After the statement completes, an entry for each successfully loaded file is written to the `aurora_s3_load_history` table.

### Verifying loaded files using the `aurora_s3_load_history` table

Every successful `LOAD DATA FROM S3` statement updates the `aurora_s3_load_history` table in the `mysql` schema with an entry for each file that was loaded.

After you run the `LOAD DATA FROM S3` statement, you can verify which files were loaded by querying the `aurora_s3_load_history` table. To see the files that were loaded from one iteration of the statement, use the `WHERE` clause to filter the records on the Amazon S3 URI for the manifest file used in the statement. If you have used the same manifest file before, filter the results using the `timestamp` field.

```
select * from mysql.aurora_s3_load_history where load_prefix = 'S3_URI';
```

The following table describes the fields in the `aurora_s3_load_history` table.

Field	Description
<code>load_prefix</code>	The URI that was specified in the load statement. This URI can map to any of the following: <ul style="list-style-type: none"> <li>• A single data file for a <code>LOAD DATA FROM S3 FILE</code> statement</li> <li>• An Amazon S3 prefix that maps to multiple data files for a <code>LOAD DATA FROM S3 PREFIX</code> statement</li> <li>• A single manifest file that contains the names of files to be loaded for a <code>LOAD DATA FROM S3 MANIFEST</code> statement</li> </ul>
<code>file_name</code>	The name of a file that was loaded into Aurora from Amazon S3 using the URI identified in the <code>load_prefix</code> field.
<code>version_number</code>	The version number of the file identified by the <code>file_name</code> field that was loaded, if the Amazon S3 bucket has a version number.
<code>bytes_loaded</code>	The size of the file loaded, in bytes.
<code>load_timestamp</code>	The timestamp when the <code>LOAD DATA FROM S3</code> statement completed.

## Examples

The following statement loads data from an Amazon S3 bucket that is in the same region as the Aurora DB cluster. The statement reads the comma-delimited data in the file `customerdata.txt` that is in the `dbbucket` Amazon S3 bucket, and then loads the data into the table `store-schema.customer-table`.

```
LOAD DATA FROM S3 's3://dbbucket/customerdata.csv'  
INTO TABLE store-schema.customer-table  
FIELDS TERMINATED BY ','  
LINES TERMINATED BY '\n'  
(ID, FIRSTNAME, LASTNAME, ADDRESS, EMAIL, PHONE);
```

The following statement loads data from an Amazon S3 bucket that is in a different region from the Aurora DB cluster. The statement reads the comma-delimited data from all files that match the employee-data object prefix in the my-data Amazon S3 bucket in the us-west-2 region, and then loads the data into the employees table.

```
LOAD DATA FROM S3 PREFIX 's3-us-west-2://my-data/employee_data'  
INTO TABLE employees  
FIELDS TERMINATED BY ','  
LINES TERMINATED BY '\n'  
(ID, FIRSTNAME, LASTNAME, EMAIL, SALARY);
```

The following statement loads data from the files specified in a JSON manifest file named q1\_sales.json into the sales table.

```
LOAD DATA FROM S3 MANIFEST 's3-us-west-2://aurora-bucket/q1_sales.json'  
INTO TABLE sales  
FIELDS TERMINATED BY ','  
LINES TERMINATED BY '\n'  
(MONTH, STORE, GROSS, NET);
```

## LOAD XML FROM S3

You can use the `LOAD XML FROM S3` statement to load data from XML files stored on an Amazon S3 bucket in one of three different XML formats:

- Column names as attributes of a `<row>` element. The attribute value identifies the contents of the table field.

```
<row column1="value1" column2="value2" .../>
```

- Column names as child elements of a `<row>` element. The value of the child element identifies the contents of the table field.

```
<row>  
  <column1>value1</column1>  
  <column2>value2</column2>  
</row>
```

- Column names in the `name` attribute of `<field>` elements in a `<row>` element. The value of the `<field>` element identifies the contents of the table field.

```
<row>  
  <field name='column1'>value1</field>  
  <field name='column2'>value2</field>  
</row>
```

## Syntax

```
LOAD XML FROM S3 'S3-URI'
```

```
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[ROWS IDENTIFIED BY '<element-name>']
[IGNORE number {LINES | ROWS}]
[(field_name_or_user_var,...)]
[SET col_name = expr,...]
```

## Parameters

Following, you can find a list of the required and optional parameters used by the `LOAD DATA FROM S3` statement. You can find more details about some of these parameters in [LOAD XML syntax](#) in the MySQL documentation.

- **FILE | PREFIX** – Identifies whether to load the data from a single file, or from all files that match a given prefix. `FILE` is the default.
- **REPLACE | IGNORE** – Determines what action to take if an input row as the same unique key values as an existing row in the database table.
  - Specify `REPLACE` if you want the input row to replace the existing row in the table.
  - Specify `IGNORE` if you want to discard the input row. `IGNORE` is the default.
- **INTO TABLE** – Identifies the name of the database table to load the input rows into.
- **PARTITION** – Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.
- **CHARACTER SET** – Identifies the character set of the data in the input file.
- **ROWS IDENTIFIED BY** – Identifies the element name that identifies a row in the input file. The default is `<row>`.
- **IGNORE *number* LINES | ROWS** – Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use `IGNORE 1 LINES` to skip over the first line in the text file, or `IGNORE 2 ROWS` to skip over the first two rows of data in the input XML.
- ***field\_name\_or\_user\_var*, ...** – Specifies a comma-separated list of one or more XML element names or user variables that identify which elements to load by name. The name of a user variable used for this purpose must match the name of an element from the XML file, prefixed with `@`. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of `table1`, and sets the value of the `table_column2` column in `table1` to the input value of the second column divided by 100.

```
LOAD XML FROM S3 's3://mybucket/data.xml'
  INTO TABLE table1
  (column1, @var1)
  SET table_column2 = @var1/100;
```

- **SET** – Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of `table1` to the values in the first two columns from the input file, and then sets the value of the `column3` in `table1` to the current time stamp.

```
LOAD XML FROM S3 's3://mybucket/data.xml'
  INTO TABLE table1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can use subqueries in the right side of `SET` assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you cannot use a subquery to select from the table that is being loaded.

# Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket

You can use the `SELECT INTO OUTFILE S3` statement to query data from an Amazon Aurora MySQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. You can use this functionality to skip bringing the data down to the client first, and then copying it from the client to Amazon S3. The `LOAD DATA FROM S3` statement can use the files created by this statement to load data into an Aurora DB cluster. For more information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket \(p. 903\)](#).

If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can't save data to a bucket that is encrypted with a customer managed key.

This feature currently isn't available for Aurora Serverless clusters.

### Note

You can save DB cluster snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see [Exporting DB cluster snapshot data to Amazon S3 \(p. 396\)](#).

## Giving Aurora MySQL access to Amazon S3

Before you can save data into an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.

### To give Aurora MySQL access to Amazon S3

1. Create an AWS Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see [Creating an IAM policy to access Amazon S3 resources \(p. 892\)](#).
2. Create an IAM role, and attach the IAM policy you created in [Creating an IAM policy to access Amazon S3 resources \(p. 892\)](#) to the new IAM role. For instructions, see [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#).
3. For Aurora MySQL version 1 or 2, set either the `aurora_select_into_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_select_into_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.

For Aurora MySQL version 3, use `aws_default_s3_role`.

If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database.

For more information about DB cluster parameters, see [Amazon Aurora DB cluster and DB instance parameters \(p. 217\)](#).

4. To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#) with the DB cluster.

For an Aurora global database, associate the role with each Aurora cluster in the global database.

For information about associating an IAM role with a DB cluster, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster \(p. 898\)](#).

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services \(p. 902\)](#).

For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

## Granting privileges to save data in Aurora MySQL

The database user that issues the `SELECT INTO OUTFILE S3` statement must have a specific role or privilege. In Aurora MySQL version 3, you grant the `AWS_SELECT_S3_ACCESS` role. In Aurora MySQL version 1 or 2, you grant the `SELECT INTO S3` privilege. The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:

```
GRANT AWS_SELECT_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

### Tip

When you use the role technique in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in [Role-based privilege model \(p. 664\)](#). You can also find more details in [Using Roles in the MySQL Reference Manual](#).

This only applies to the current active session. When you reconnect, you have to run the `SET ROLE` statement again to grant privileges. For more information, see [SET ROLE statement](#) in the [MySQL Reference Manual](#).

You can also use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you don't have to call the `SET ROLE` statement explicitly to activate a role. For more information, see [activate\\_all\\_roles\\_on\\_login](#) in the [MySQL Reference Manual](#).

Use the following statement for Aurora MySQL version 1 or 2:

```
GRANT SELECT INTO S3 ON *.* TO 'user'@'domain-or-ip-address'
```

The `AWS_SELECT_S3_ACCESS` role and `SELECT INTO S3` privilege are specific to Amazon Aurora MySQL and are not available for MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora MySQL DB cluster as the replication master and a MySQL database as the replication client, then the `GRANT` statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on an RDS for MySQL DB

instance, use the `mysql_rds_skip_repl_error` procedure. To skip the error on an external MySQL database, use the `SET GLOBAL sql_slave_skip_counter` statement (Aurora MySQL version 1 and 2) or `SET GLOBAL sql_replica_skip_counter` statement (Aurora MySQL version 3).

## Specifying a path to an Amazon S3 bucket

The syntax for specifying a path to store the data and manifest files on an Amazon S3 bucket is similar to that used in the `LOAD DATA FROM S3 PREFIX` statement, as shown following.

```
s3-region://bucket-name/file-prefix
```

The path includes the following values:

- **region (optional)** – The AWS Region that contains the Amazon S3 bucket to save the data into. This value is optional. If you don't specify a `region` value, then Aurora saves your files into Amazon S3 in the same region as your DB cluster.
- **bucket-name** – The name of the Amazon S3 bucket to save the data into. Object prefixes that identify a virtual folder path are supported.
- **file-prefix** – The Amazon S3 object prefix that identifies the files to be saved in Amazon S3.

The data files created by the `SELECT INTO OUTFILE S3` statement use the following path, in which `00000` represents a 5-digit, zero-based integer number.

```
s3-region://bucket-name/file-prefix.part_00000
```

For example, suppose that a `SELECT INTO OUTFILE S3` statement specifies `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files. The specified Amazon S3 bucket contains the following data files.

- `s3-us-west-2://bucket/prefix.part_00000`
- `s3-us-west-2://bucket/prefix.part_00001`
- `s3-us-west-2://bucket/prefix.part_00002`

## Creating a manifest to list data files

You can use the `SELECT INTO OUTFILE S3` statement with the `MANIFEST ON` option to create a manifest file in JSON format that lists the text files created by the statement. The `LOAD DATA FROM S3` statement can use the manifest file to load the data files back into an Aurora MySQL DB cluster. For more information about using a manifest to load data files from Amazon S3 into an Aurora MySQL DB cluster, see [Using a manifest to specify data files to load \(p. 906\)](#).

The data files included in the manifest created by the `SELECT INTO OUTFILE S3` statement are listed in the order that they're created by the statement. For example, suppose that a `SELECT INTO OUTFILE S3` statement specified `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files and a manifest file. The specified Amazon S3 bucket contains a manifest file named `s3-us-west-2://bucket/prefix.manifest`, that contains the following information.

```
{
  "entries": [
    {
      "url": "s3-us-west-2://bucket/prefix.part_00000"
    },
    {
      "url": "s3-us-west-2://bucket/prefix.part_00001"
    },
    {
      "url": "s3-us-west-2://bucket/prefix.part_00002"
    }
  ]
}
```

```

        "url":"s3-us-west-2://bucket/prefix.part_00001"
    },
    {
        "url":"s3-us-west-2://bucket/prefix.part_00002"
    }
]
}

```

## SELECT INTO OUTFILE S3

You can use the `SELECT INTO OUTFILE S3` statement to query data from a DB cluster and save it directly into delimited text files stored in an Amazon S3 bucket. Compressed files are not supported. Encrypted files are supported starting in Aurora MySQL 2.09.0.

### Syntax

```

SELECT
    [ALL | DISTINCT | DISTINCTROW ]
    [HIGH_PRIORITY]
    [STRAIGHT_JOIN]
    [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
    [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
    select_expr [, select_expr ...]
    [FROM table_references
        [PARTITION partition_list]
    [WHERE where_condition]
    [GROUP BY {col_name | expr | position}
        [ASC | DESC], ... [WITH ROLLUP]]
    [HAVING where_condition]
    [ORDER BY {col_name | expr | position}
        [ASC | DESC], ...]
    [LIMIT {[offset,] row_count | row_count OFFSET offset}]]
INTO OUTFILE S3 's3_uri'
[CHARACTER SET charset_name]
[export_options]
[MANIFEST {ON | OFF}]
[OVERWRITE {ON | OFF}]

export_options:
    [FORMAT {CSV|TEXT} [HEADER]]
    [{FIELDS | COLUMNS}
        [TERMINATED BY 'string']
        [[OPTIONALLY] ENCLOSED BY 'char']
        [ESCAPED BY 'char']
    ]
    [LINES
        [STARTING BY 'string']
        [TERMINATED BY 'string']
    ]
]

```

### Parameters

Following, you can find a list of the required and optional parameters used by the `SELECT INTO OUTFILE S3` statement that are specific to Aurora.

- **s3-uri** – Specifies the URI for an Amazon S3 prefix to use. Specify the URI using the syntax described in [Specifying a path to an Amazon S3 bucket \(p. 913\)](#).
- **FORMAT {CSV|TEXT} [HEADER]** – Optionally saves the data in CSV format. This syntax is available in Aurora MySQL version 2.07.0 and later.

The `TEXT` option is the default and produces the existing MySQL export format.

The csv option produces comma-separated data values. The CSV format follows the specification in [RFC-4180](#). If you specify the optional keyword HEADER, the output file contains one header line. The labels in the header line correspond to the column names from the SELECT statement. You can use the CSV files for training data models for use with AWS ML services. For more information about using exported Aurora data with AWS ML services, see [Exporting data to Amazon S3 for SageMaker model training \(p. 933\)](#).

- **MANIFEST {ON | OFF}** – Indicates whether a manifest file is created in Amazon S3. The manifest file is a JavaScript Object Notation (JSON) file that can be used to load data into an Aurora DB cluster with the LOAD DATA FROM S3 MANIFEST statement. For more information about LOAD DATA FROM S3 MANIFEST, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket \(p. 903\)](#).

If MANIFEST ON is specified in the query, the manifest file is created in Amazon S3 after all data files have been created and uploaded. The manifest file is created using the following path:

```
s3-region://bucket-name/file-prefix.manifest
```

For more information about the format of the manifest file's contents, see [Creating a manifest to list data files \(p. 913\)](#).

- **OVERWRITE {ON | OFF}** – Indicates whether existing files in the specified Amazon S3 bucket are overwritten. If OVERWRITE ON is specified, existing files that match the file prefix in the URI specified in s3-uri are overwritten. Otherwise, an error occurs.

You can find more details about other parameters in [SELECT syntax](#) and [LOAD DATA INFILE syntax](#), in the MySQL documentation.

## Considerations

The number of files written to the Amazon S3 bucket depends on the amount of data selected by the SELECT INTO OUTFILE S3 statement and the file size threshold for Aurora MySQL. The default file size threshold is 6 gigabytes (GB). If the data selected by the statement is less than the file size threshold, a single file is created; otherwise, multiple files are created. Other considerations for files created by this statement include the following:

- Aurora MySQL guarantees that rows in data files are not split across file boundaries. For multiple files, the size of every data file except the last is typically close to the file size threshold. However, occasionally staying under the file size threshold results in a row being split across two data files. In this case, Aurora MySQL creates a data file that keeps the row intact, but might be larger than the file size threshold.
- Because each SELECT statement in Aurora MySQL runs as an atomic transaction, a SELECT INTO OUTFILE S3 statement that selects a large data set might run for some time. If the statement fails for any reason, you might need to start over and issue the statement again. If the statement fails, however, files already uploaded to Amazon S3 remain in the specified Amazon S3 bucket. You can use another statement to upload the remaining data instead of starting over again.
- If the amount of data to be selected is large (more than 25 GB), we recommend that you use multiple SELECT INTO OUTFILE S3 statements to save the data to Amazon S3. Each statement should select a different portion of the data to be saved, and also specify a different file\_prefix in the s3-uri parameter to use when saving the data files. Partitioning the data to be selected with multiple statements makes it easier to recover from an error in one statement. If an error occurs for one statement, only a portion of data needs to be re-selected and uploaded to Amazon S3. Using multiple statements also helps to avoid a single long-running transaction, which can improve performance.
- If multiple SELECT INTO OUTFILE S3 statements that use the same file\_prefix in the s3-uri parameter run in parallel to select data into Amazon S3, the behavior is undefined.
- Metadata, such as table schema or file metadata, is not uploaded by Aurora MySQL to Amazon S3.

- In some cases, you might re-run a `SELECT INTO OUTFILE S3` query, such as to recover from a failure. In these cases, you must either remove any existing data files in the Amazon S3 bucket with the same file prefix specified in `s3-uri`, or include `OVERWRITE ON` in the `SELECT INTO OUTFILE S3` query.

The `SELECT INTO OUTFILE S3` statement returns a typical MySQL error number and response on success or failure. If you don't have access to the MySQL error number and response, the easiest way to determine when it's done is by specifying `MANIFEST ON` in the statement. The manifest file is the last file written by the statement. In other words, if you have a manifest file, the statement has completed.

Currently, there's no way to directly monitor the progress of the `SELECT INTO OUTFILE S3` statement while it runs. However, suppose that you're writing a large amount of data from Aurora MySQL to Amazon S3 using this statement, and you know the size of the data selected by the statement. In this case, you can estimate progress by monitoring the creation of data files in Amazon S3.

To do so, you can use the fact that a data file is created in the specified Amazon S3 bucket for about every 6 GB of data selected by the statement. Divide the size of the data selected by 6 GB to get the estimated number of data files to create. You can then estimate the progress of the statement by monitoring the number of files uploaded to Amazon S3 while the statement runs.

## Examples

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in a different region from the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character. The statement returns an error if files that match the `sample_employee_data` file prefix exist in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3-us-west-2://aurora-select-into-s3-pdx/
sample_employee_data'
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n';
```

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in the same region as the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character, and also a manifest file. The statement returns an error if files that match the `sample_employee_data` file prefix exist in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3://aurora-select-into-s3-pdx/
sample_employee_data'
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
MANIFEST ON;
```

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in a different region from the Aurora DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character. The statement overwrites any existing files that match the `sample_employee_data` file prefix in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3-us-west-2://aurora-select-into-s3-pdx/
sample_employee_data'
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
OVERWRITE ON;
```

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in the same region as the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character, and also a manifest file. The statement overwrites any existing files that match the `sample_employee_data` file prefix in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3://aurora-select-into-s3-pdx/
sample_employee_data'
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
MANIFEST ON
OVERWRITE ON;
```

## Invoking a Lambda function from an Amazon Aurora MySQL DB cluster

You can invoke an AWS Lambda function from an Amazon Aurora MySQL-Compatible Edition DB cluster with the native function `lambda_sync` or `lambda_async`. Before invoking a Lambda function from an Aurora MySQL, the Aurora DB cluster must have access to Lambda. For details about granting access to Aurora MySQL, see [Giving Aurora access to Lambda \(p. 917\)](#). For information about the `lambda_sync` and `lambda_async` stored functions, see [Invoking a Lambda function with an Aurora MySQL native function \(p. 918\)](#).

You can also call an AWS Lambda function by using a stored procedure. However, using a stored procedure is deprecated. We strongly recommend using an Aurora MySQL native function if you are using one of the following Aurora MySQL versions:

- Aurora MySQL version 1.16 and later, for MySQL 5.6-compatible clusters.
- Aurora MySQL version 2.06 and later, for MySQL 5.7-compatible clusters.
- Aurora MySQL version 3.01 and higher, for MySQL 8.0-compatible clusters. The stored procedure is not available in Aurora MySQL version 3.

### Topics

- [Giving Aurora access to Lambda \(p. 917\)](#)

- [Invoking a Lambda function with an Aurora MySQL stored procedure \(deprecated\) \(p. 921\)](#)

## Giving Aurora access to Lambda

Before you can invoke Lambda functions from an Aurora MySQL DB cluster, make sure to first give your cluster permission to access Lambda.

## To give Aurora MySQL access to Lambda

1. Create an AWS Identity and Access Management (IAM) policy that provides the permissions that allow your Aurora MySQL DB cluster to invoke Lambda functions. For instructions, see [Creating an IAM policy to access AWS Lambda resources \(p. 894\)](#).
2. Create an IAM role, and attach the IAM policy you created in [Creating an IAM policy to access AWS Lambda resources \(p. 894\)](#) to the new IAM role. For instructions, see [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#).
3. Set the `aws_default_lambda_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role.

If the cluster is part of an Aurora global database, apply the same setting for each Aurora cluster in the global database.

For more information about DB cluster parameters, see [Amazon Aurora DB cluster and DB instance parameters \(p. 217\)](#).

4. To permit database users in an Aurora MySQL DB cluster to invoke Lambda functions, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#) with the DB cluster. For information about associating an IAM role with a DB cluster, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster \(p. 898\)](#).

If the cluster is part of an Aurora global database, associate the role with each Aurora cluster in the global database.

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Lambda. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services \(p. 902\)](#).

If the cluster is part of an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

## Invoking a Lambda function with an Aurora MySQL native function

### Note

You can call the native functions `lambda_sync` and `lambda_async` when you use Aurora MySQL version 1.16 and later, Aurora MySQL 2.06 and later, or Aurora MySQL version 3.01 and higher. For more information about Aurora MySQL versions, see [Database engine updates for Amazon Aurora MySQL \(p. 990\)](#).

You can invoke an AWS Lambda function from an Aurora MySQL DB cluster by calling the native functions `lambda_sync` and `lambda_async`. This approach can be useful when you want to integrate your database running on Aurora MySQL with other AWS services. For example, you might want to send a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.

## Working with native functions to invoke a Lambda function

The `lambda_sync` and `lambda_async` functions are built-in, native functions that invoke a Lambda function synchronously or asynchronously. When you must know the result of the Lambda function before moving on to another action, use the synchronous function `lambda_sync`. When you don't need to know the result of the Lambda function before moving on to another action, use the asynchronous function `lambda_async`.

In Aurora MySQL version 3, the user invoking a native function must be granted the `AWS_LAMBDA_ACCESS` role. To grant this role to a user, connect to the DB instance as the administrative user, and run the following statement.

```
GRANT AWS_LAMBDA_ACCESS TO user@domain-or-ip-address
```

You can revoke this role by running the following statement.

```
REVOKE AWS_LAMBDA_ACCESS FROM user@domain-or-ip-address
```

**Tip**

When you use the role technique in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in [Role-based privilege model \(p. 664\)](#). You can also find more details in [Using Roles in the MySQL Reference Manual](#).

This only applies to the current active session. When you reconnect, you have to run the `SET ROLE` statement again to grant privileges. For more information, see [SET ROLE statement](#) in the [MySQL Reference Manual](#).

You can also use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you don't have to call the `SET ROLE` statement explicitly to activate a role. For more information, see [activate\\_all\\_roles\\_on\\_login](#) in the [MySQL Reference Manual](#).

In Aurora MySQL version 1 and 2, the user invoking a native function must be granted the `INVOKELAMBDA` privilege. To grant this privilege to a user, connect to the DB instance as the administrative user, and run the following statement.

```
GRANT INVOKELAMBDA ON *.* TO user@domain-or-ip-address
```

You can revoke this privilege by running the following statement.

```
REVOKE INVOKELAMBDA ON *.* FROM user@domain-or-ip-address
```

### Syntax for the `lambda_sync` function

You invoke the `lambda_sync` function synchronously with the `RequestResponse` invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```
lambda_sync (
    lambda_function_ARN,
    JSON_payload
)
```

**Note**

You can use triggers to call Lambda on data-modifying statements. Remember that triggers are not run once per SQL statement, but once per row modified, one row at a time. When a trigger runs, the process is synchronous. The data-modifying statement only returns when the trigger completes.

Be careful when invoking an AWS Lambda function from triggers on tables that experience high write traffic. `INSERT`, `UPDATE`, and `DELETE` triggers are activated per row. A write-heavy workload on a table with `INSERT`, `UPDATE`, or `DELETE` triggers results in a large number of calls to your AWS Lambda function.

### Parameters for the `lambda_sync` function

The `lambda_sync` function has the following parameters.

#### *lambda\_function\_ARN*

The Amazon Resource Name (ARN) of the Lambda function to invoke.

#### *JSON\_payload*

The payload for the invoked Lambda function, in JSON format.

#### **Note**

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL versions 1 and 2 don't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

#### [Example for the lambda\\_sync function](#)

The following query based on `lambda_sync` invokes the Lambda function `BasicTestLambda` synchronously using the function ARN. The payload for the function is `{"operation": "ping"}`.

```
SELECT lambda_sync(
    'arn:aws:lambda:us-east-1:868710585169:function:BasicTestLambda',
    '{"operation": "ping"}');
```

#### [Syntax for the lambda\\_async function](#)

You invoke the `lambda_async` function asynchronously with the `Event` invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```
lambda_async (
    lambda_function_ARN,
    JSON_payload
)
```

#### [Parameters for the lambda\\_async function](#)

The `lambda_async` function has the following parameters.

#### *lambda\_function\_ARN*

The Amazon Resource Name (ARN) of the Lambda function to invoke.

#### *JSON\_payload*

The payload for the invoked Lambda function, in JSON format.

#### **Note**

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL versions 1 and 2 don't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

#### [Example for the lambda\\_async function](#)

The following query based on `lambda_async` invokes the Lambda function `BasicTestLambda` asynchronously using the function ARN. The payload for the function is `{"operation": "ping"}`.

```
SELECT lambda_async(
    'arn:aws:lambda:us-east-1:868710585169:function:BasicTestLambda',
```

```
'{"operation": "ping"}');
```

## Invoking a Lambda function with an Aurora MySQL stored procedure (deprecated)

You can invoke an AWS Lambda function from an Aurora MySQL DB cluster by calling the `mysql.lambda_async` procedure. This approach can be useful when you want to integrate your database running on Aurora MySQL with other AWS services. For example, you might want to send a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.

### Aurora MySQL version considerations

Starting in Aurora MySQL version 1.8 and Aurora MySQL version 2.06, you can use the native function method instead of these stored procedures to invoke a Lambda function. For more information about the native functions, see [Working with native functions to invoke a Lambda function \(p. 918\)](#).

Starting with Amazon Aurora version 1.16 and 2.06, the stored procedure `mysql.lambda_async` is no longer supported. If you are using an Aurora version that's higher than 1.16 or 2.06, we strongly recommend that you work with native Lambda functions instead. In Aurora MySQL version 3, the stored procedure isn't available.

### Working with the `mysql.lambda_async` procedure to invoke a Lambda function (deprecated)

The `mysql.lambda_async` procedure is a built-in stored procedure that invokes a Lambda function asynchronously. To use this procedure, your database user must have `EXECUTE` privilege on the `mysql.lambda_async` stored procedure.

#### Syntax

The `mysql.lambda_async` procedure has the following syntax.

```
CALL mysql.lambda_async (
    lambda_function_ARN,
    lambda_function_input
)
```

#### Parameters

The `mysql.lambda_async` procedure has the following parameters.

*lambda\_function\_ARN*

The Amazon Resource Name (ARN) of the Lambda function to invoke.

*lambda\_function\_input*

The input string, in JSON format, for the invoked Lambda function.

#### Examples

As a best practice, we recommend that you wrap calls to the `mysql.lambda_async` procedure in a stored procedure that can be called from different sources such as triggers or client code. This approach can help to avoid impedance mismatch issues and make it easier to invoke Lambda functions.

### Note

Be careful when invoking an AWS Lambda function from triggers on tables that experience high write traffic. `INSERT`, `UPDATE`, and `DELETE` triggers are activated per row. A write-heavy workload on a table with `INSERT`, `UPDATE`, or `DELETE` triggers results in a large number of calls to your AWS Lambda function.

Although calls to the `mysql.lambda_async` procedure are asynchronous, triggers are synchronous. A statement that results in a large number of trigger activations doesn't wait for the call to the AWS Lambda function to complete, but it does wait for the triggers to complete before returning control to the client.

### Example Example: Invoke an AWS Lambda function to send email

The following example creates a stored procedure that you can call in your database code to send an email using a Lambda function.

#### AWS Lambda Function

```
import boto3

ses = boto3.client('ses')

def SES_send_email(event, context):

    return ses.send_email(
        Source=event['email_from'],
        Destination={
            'ToAddresses': [
                event['email_to'],
            ],
        },
        Message={
            'Subject': {
                'Data': event['email_subject']
            },
            'Body': {
                'Text': {
                    'Data': event['email_body']
                }
            }
        }
    )
```

#### Stored Procedure

```
DROP PROCEDURE IF EXISTS SES_send_email;
DELIMITER ;;
CREATE PROCEDURE SES_send_email(IN email_from VARCHAR(255),
                                IN email_to VARCHAR(255),
                                IN subject VARCHAR(255),
                                IN body TEXT) LANGUAGE SQL
BEGIN
    CALL mysql.lambda_async(
        'arn:aws:lambda:us-west-2:123456789012:function:SES_send_email',
        CONCAT('{"email_to" : "', email_to,
               '", "email_from" : "', email_from,
               '", "email_subject" : "', subject,
               '", "email_body" : "', body, '"}')
    );
END
;;
```

```
DELIMITER ;
```

### Call the Stored Procedure to Invoke the AWS Lambda Function

```
mysql> call SES_send_email('example_from@amazon.com', 'example_to@amazon.com', 'Email subject', 'Email content');
```

### Example Example: Invoke an AWS Lambda function to publish an event from a trigger

The following example creates a stored procedure that publishes an event by using Amazon SNS. The code calls the procedure from a trigger when a row is added to a table.

#### AWS Lambda Function

```
import boto3

sns = boto3.client('sns')

def SNS_publish_message(event, context):

    return sns.publish(
        TopicArn='arn:aws:sns:us-west-2:123456789012:Sample_Topic',
        Message=event['message'],
        Subject=event['subject'],
        MessageStructure='string'
    )
```

#### Stored Procedure

```
DROP PROCEDURE IF EXISTS SNS_Publish_Message;
DELIMITER ;;
CREATE PROCEDURE SNS_Publish_Message (IN subject VARCHAR(255),
                                         IN message TEXT) LANGUAGE SQL
BEGIN
    CALL mysql.lambda_async('arn:aws:lambda:us-
west-2:123456789012:function:SNS_publish_message',
                           CONCAT('{ "subject" : "', subject,
                                  '", "message" : "', message, '" }'))
END
;;
DELIMITER ;
```

#### Table

```
CREATE TABLE 'Customer_Feedback' (
    'id' int(11) NOT NULL AUTO_INCREMENT,
    'customer_name' varchar(255) NOT NULL,
    'customer_feedback' varchar(1024) NOT NULL,
    PRIMARY KEY ('id')
) ENGINE=InnoDB DEFAULT CHARSET=utf8;
```

#### Trigger

```
DELIMITER ;;
CREATE TRIGGER TR_Customer_Feedback_AI
    AFTER INSERT ON Customer_Feedback
    FOR EACH ROW
```

```
BEGIN
    SELECT CONCAT('New customer feedback from ', NEW.customer_name), NEW.customer_feedback
    INTO @subject, @feedback;
    CALL SNS_Publish_Message(@subject, @feedback);
END
;;
DELIMITER ;
```

### Insert a Row into the Table to Trigger the Notification

```
mysql> insert into Customer_Feedback (customer_name, customer_feedback) VALUES ('Sample
Customer', 'Good job guys!');
```

## Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs

You can configure your Aurora MySQL DB cluster to publish general, slow, audit, and error log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

To publish logs to CloudWatch Logs, the respective logs must be enabled. Error logs are enabled by default, but you must enable the other types of logs explicitly. For information about enabling logs in MySQL, see [Selecting general query and slow query log output destinations](#) in the MySQL documentation. For more information about enabling Aurora MySQL audit logs, see [Enabling Advanced Auditing \(p. 823\)](#).

#### Note

Be aware of the following:

- You can't publish logs to CloudWatch Logs for the China (Ningxia) region.
- If exporting log data is disabled, Aurora doesn't delete existing log groups or log streams. If exporting log data is disabled, existing log data remains available in CloudWatch Logs, depending on log retention, and you still incur charges for stored audit log data. You can delete log streams and log groups using the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API.
- An alternative way to publish audit logs to CloudWatch Logs is by enabling advanced auditing and setting the cluster-level DB parameter `server_audit_logs_upload` to 1. The default for the `server_audit_logs_upload` parameter is 0.

If you use this alternative method, you must have an IAM role to access CloudWatch Logs and set the `aws_default_logs_role` cluster-level parameter to the ARN for this role. For information about creating the role, see [Setting up IAM roles to access AWS services \(p. 892\)](#). However, if you have the `AWSServiceRoleForRDS` service-linked role, it provides access to CloudWatch Logs and overrides any custom-defined roles. For information service-linked roles for Amazon RDS, see [Using service-linked roles for Amazon Aurora \(p. 1724\)](#).

- If you don't want to export audit logs to CloudWatch Logs, make sure that all methods of exporting audit logs are disabled. These methods are the AWS Management Console, the AWS CLI, the RDS API, and the `server_audit_logs_upload` parameter.
- The procedure is slightly different for Aurora Serverless v1 clusters than for clusters with provisioned or Aurora Serverless v2 instances. Aurora Serverless v1 clusters automatically upload all the kinds of logs that you enable through the configuration parameters. Therefore, you turn on or turn off log upload for Serverless clusters by turning different log types on and off in the DB cluster parameter group. You don't modify the settings of the cluster itself.

through the AWS Management Console, AWS CLI, or RDS API. For information about turning on and off MySQL logs for Aurora Serverless v1 clusters, see [Parameter groups for Aurora Serverless v1 \(p. 1554\)](#).

## Console

You can publish Aurora MySQL logs for provisioned clusters to CloudWatch Logs with the console.

### To publish Aurora MySQL logs from the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora MySQL DB cluster that you want to publish the log data for.
4. Choose **Modify**.
5. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
6. Choose **Continue**, and then choose **Modify DB Cluster** on the summary page.

## AWS CLI

You can publish Aurora MySQL logs for provisioned clusters with the AWS CLI. To do so, you run the [modify-db-cluster](#) AWS CLI command with the following options:

- **--db-cluster-identifier**—The DB cluster identifier.
- **--cloudwatch-logs-export-configuration**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs by running one of the following AWS CLI commands:

- [create-db-cluster](#)
- [restore-db-cluster-from-s3](#)
- [restore-db-cluster-from-snapshot](#)
- [restore-db-cluster-to-point-in-time](#)

Run one of these AWS CLI commands with the following options:

- **--db-cluster-identifier**—The DB cluster identifier.
- **--engine**—The database engine.
- **--enable-cloudwatch-logs-exports**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other options might be required depending on the AWS CLI command that you run.

### Example

The following command modifies an existing Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
```

```
--db-cluster-identifier mydbcluster \
--cloudwatch-logs-export-configuration '{"EnableLogTypes": \
["error","general","slowquery","audit"]}'
```

For Windows:

```
aws rds modify-db-cluster ^
--db-cluster-identifier mydbcluster ^
--cloudwatch-logs-export-configuration '{"EnableLogTypes": \
["error","general","slowquery","audit"]}'
```

### Example

The following command creates an Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
--db-cluster-identifier mydbcluster \
--engine aurora \
--enable-cloudwatch-logs-exports '[{"error","general","slowquery","audit"}]
```

For Windows:

```
aws rds create-db-cluster ^
--db-cluster-identifier mydbcluster ^
--engine aurora ^
--enable-cloudwatch-logs-exports '[{"error","general","slowquery","audit"}]'
```

## RDS API

You can publish Aurora MySQL logs for provisioned clusters with the RDS API. To do so, you run the [ModifyDBCluster](#) operation with the following options:

- **DBClusterIdentifier**—The DB cluster identifier.
- **CloudwatchLogsExportConfiguration**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs with the RDS API by running one of the following RDS API operations:

- [CreateDBCluster](#)
- [RestoreDBClusterFromS3](#)
- [RestoreDBClusterFromSnapshot](#)
- [RestoreDBClusterToPointInTime](#)

Run the RDS API operation with the following parameters:

- **DBClusterIdentifier**—The DB cluster identifier.
- **Engine**—The database engine.

- `EnableCloudwatchLogsExports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other parameters might be required depending on the AWS CLI command that you run.

## Monitoring log events in Amazon CloudWatch

After enabling Aurora MySQL log events, you can monitor the events in Amazon CloudWatch Logs. A new log group is automatically created for the Aurora DB cluster under the following prefix, in which `cluster-name` represents the DB cluster name, and `log_type` represents the log type.

```
/aws/rds/cluster/cluster-name/log_type
```

For example, if you configure the export function to include the slow query log for a DB cluster named `mydbcluster`, slow query data is stored in the `/aws/rds/cluster/mydbcluster/slowquery` log group.

The events from all instances in your cluster are pushed to a log group using different log streams. The behavior depends on which of the following conditions is true:

- A log group with the specified name exists.

Aurora uses the existing log group to export log data for the cluster. To create log groups with predefined log retention periods, metric filters, and customer access, you can use automated configuration, such as AWS CloudFormation.
- A log group with the specified name doesn't exist.

When a matching log entry is detected in the log file for the instance, Aurora MySQL creates a new log group in CloudWatch Logs automatically. The log group uses the default log retention period of **Never Expire**.

To change the log retention period, use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API. For more information about changing log retention periods in CloudWatch Logs, see [Change log data retention in CloudWatch Logs](#).

To search for information within the log events for a DB cluster, use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API. For more information about searching and filtering log data, see [Searching and filtering log data](#).

## Using machine learning (ML) with Aurora MySQL

With Aurora machine learning, you can add machine learning-based predictions to database applications using the SQL language. Aurora machine learning uses a highly optimized integration between the Aurora database and the AWS machine learning (ML) services SageMaker and Amazon Comprehend.

Benefits of Aurora machine learning include the following:

- You can add ML-based predictions to your existing database applications. You don't need to build custom integrations or learn separate tools. You can embed machine learning processing directly into your SQL query as calls to stored functions.
- The ML integration is a fast way to enable ML services to work with transactional data. You don't have to move the data out of the database to perform the machine learning operations. You don't have to convert or reimport the results of the machine learning operations to use them in your database application.
- You can use your existing governance policies to control who has access to the underlying data and to the generated insights.

AWS ML Services are managed services that are set up and run in their own production environments. Currently, Aurora machine learning integrates with Amazon Comprehend for sentiment analysis and SageMaker for a wide variety of ML algorithms.

For details about using Aurora and Amazon Comprehend together, see [Using Amazon Comprehend for sentiment detection \(p. 936\)](#). For general information about Amazon Comprehend, see [Amazon Comprehend](#).

For details about using Aurora and SageMaker together, see [Using SageMaker to run your own ML models \(p. 934\)](#). For general information about SageMaker, see [SageMaker](#).

#### Topics

- [Prerequisites for Aurora machine learning \(p. 928\)](#)
- [Enabling Aurora machine learning \(p. 928\)](#)
- [Exporting data to Amazon S3 for SageMaker model training \(p. 933\)](#)
- [Using SageMaker to run your own ML models \(p. 934\)](#)
- [Using Amazon Comprehend for sentiment detection \(p. 936\)](#)
- [Performance considerations for Aurora machine learning \(p. 937\)](#)
- [Monitoring Aurora machine learning \(p. 938\)](#)
- [Limitations of Aurora machine learning \(p. 939\)](#)

## Prerequisites for Aurora machine learning

You can upgrade an Aurora cluster that's running a lower version of Aurora MySQL to a supported higher version if you want to use Aurora machine learning with that cluster. For more information, see [Database engine updates for Amazon Aurora MySQL \(p. 990\)](#).

For more information about Regions and Aurora version availability, see [Aurora machine learning \(p. 24\)](#).

## Enabling Aurora machine learning

Enabling the ML capabilities involves the following steps:

- You enable the Aurora cluster to access the Amazon machine learning services SageMaker or Amazon Comprehend, depending the kinds of ML algorithms you want for your application.
- For SageMaker, then you use the Aurora `CREATE FUNCTION` statement to set up stored functions that access inference features.

#### Note

Aurora machine learning includes built-in functions that call Amazon Comprehend for sentiment analysis. You don't need to run any `CREATE FUNCTION` statements if you only use Amazon Comprehend.

#### Topics

- [Setting up IAM access to Amazon Comprehend and SageMaker \(p. 928\)](#)
- [Granting SQL privileges for invoking Aurora machine learning services \(p. 933\)](#)
- [Enabling network communication from Aurora MySQL to other AWS services \(p. 933\)](#)

## Setting up IAM access to Amazon Comprehend and SageMaker

Before you can access SageMaker and Amazon Comprehend services, enable the Aurora MySQL cluster to access AWS ML services. For your Aurora MySQL DB cluster to access AWS ML services on your behalf,

create and configure AWS Identity and Access Management (IAM) roles. These roles authorize the users of your Aurora MySQL database to access AWS ML services.

When you use the AWS Management Console, AWS does the IAM setup for you automatically. You can skip the following information and follow the procedure in [Connecting an Aurora DB cluster to Amazon S3, SageMaker, or Amazon Comprehend using the console \(p. 929\)](#).

Setting up the IAM roles for SageMaker or Amazon Comprehend using the AWS CLI or the RDS API consists of the following steps:

1. Create an IAM policy to specify which SageMaker endpoints can be invoked by your Aurora MySQL cluster or to enable access to Amazon Comprehend.
2. Create an IAM role to permit your Aurora MySQL database cluster to access AWS ML services. The IAM policy created above is attached to the IAM role.
3. To permit the Aurora MySQL database cluster to access AWS ML services, you associate the IAM role that you created above to the database cluster.
4. To permit database applications to invoke AWS ML services, you must also grant privileges to specific database users. For SageMaker, because the calls to the endpoints are wrapped inside a stored function, you also grant `EXECUTE` privileges on the stored functions to any database users that call them.

For general information about how to permit your Aurora MySQL DB cluster to access other AWS services on your behalf, see [Authorizing Amazon Aurora MySQL to access other AWS services on your behalf \(p. 891\)](#).

#### [Connecting an Aurora DB cluster to Amazon S3, SageMaker, or Amazon Comprehend using the console](#)

Aurora machine learning requires that your DB cluster use some combination of Amazon S3, SageMaker, and Amazon Comprehend. Amazon Comprehend is for sentiment analysis. SageMaker is for a wide variety of machine learning algorithms. For Aurora machine learning, Amazon S3 is only for training SageMaker models. You only need to use Amazon S3 with Aurora machine learning if you don't already have a trained model available and the training is your responsibility. To connect a DB cluster to these services requires that you set up an AWS Identity and Access Management (IAM) role for each Amazon service. The IAM role enables users of your DB cluster to authenticate with the corresponding service.

To generate the IAM roles for Amazon S3, SageMaker, or Amazon Comprehend, repeat the following steps for each service that you need.

#### **To connect a DB cluster to an Amazon service**

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the Aurora MySQL DB cluster that you want to use.
3. Choose the **Connectivity & security** tab.
4. Choose **Select a service to connect to this cluster** in the **Manage IAM roles** section., and choose the service that you want to connect to:
  - **Amazon S3**
  - **Amazon Comprehend**
  - **SageMaker**
5. Choose **Connect service**.
6. Enter the required information for the specific service on the **Connect cluster** window:

- For SageMaker, enter the Amazon Resource Name (ARN) of an SageMaker endpoint. For details about what the endpoint represents, see [Deploy a model on Amazon SageMaker hosting services](#).

In the navigation pane of the [SageMaker console](#), choose **Endpoints** and copy the ARN of the endpoint you want to use.

- For Amazon Comprehend, don't specify any additional parameter.
- For Amazon S3, enter the ARN of an Amazon S3 bucket to use.

The format of an Amazon S3 bucket ARN is `arn:aws:s3:::bucket_name`. Ensure that the Amazon S3 bucket that you use is set up with the requirements for training SageMaker models. When you train a model, your Aurora DB cluster requires permission to export data to the Amazon S3 bucket, and also to import data from the bucket.

To learn more about Amazon S3 bucket ARNs, see [Specifying resources in a policy](#) in the *Amazon Simple Storage Service User Guide*. For more about using an Amazon S3 bucket with SageMaker, see [Step 1: Create an Amazon S3 bucket](#) in the *Amazon SageMaker Developer Guide*.

7. Choose **Connect service**.
8. Aurora creates a new IAM role and adds it to the DB cluster's list of **Current IAM roles for this cluster**. The IAM role's status is initially **In progress**. The IAM role name is autogenerated with the following pattern for each connected service:
  - The Amazon S3 IAM role name pattern is `rds-cluster_ID-S3-policy-timestamp`.
  - The SageMaker IAM role name pattern is `rds-cluster_ID-SageMaker-policy-timestamp`.
  - The Amazon Comprehend IAM role name pattern is `rds-cluster_ID-Comprehend-policy-timestamp`.

Aurora also creates a new IAM policy and attaches it to the role. The policy name follows a similar naming convention and also has a timestamp.

### [Creating an IAM policy to access SageMaker \(AWS CLI only\)](#)

#### **Note**

When you use the AWS Management Console, Aurora creates the IAM policy automatically. In that case, you can skip this section.

The following policy adds the permissions required by Aurora MySQL to invoke an SageMaker function on your behalf. You can specify all of your SageMaker endpoints that you need your database applications to access from your Aurora MySQL cluster in a single policy. The policy allows you to specify the AWS Region for an SageMaker endpoint. However, an Aurora MySQL cluster can only invoke SageMaker models deployed in the same AWS Region as the cluster.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowAuroraToInvokeRCFEndPoint",  
            "Effect": "Allow",  
            "Action": "sagemaker:InvokeEndpoint",  
            "Resource": "arn:aws:sagemaker:region:123456789012:endpoint/endpointName"  
        }  
    ]  
}
```

The following command performs the same operation through the AWS CLI.

```
aws iam put-role-policy --role-name role_name --policy-name policy_name
--policy-document '{ "Version": "2012-10-17", "Statement": [ { "Sid": "AllowAuroraToInvokeRCFEndpoint", "Effect": "Allow", "Action": "sagemaker:InvokeEndpoint", "Resource": "arn:aws:sagemaker:region:123456789012:endpoint/endpointName" } ]}'
```

### Creating an IAM policy to access Amazon Comprehend (AWS CLI only)

#### Note

When you use the AWS Management Console, Aurora creates the IAM policy automatically. In that case, you can skip this section.

The following policy adds the permissions required by Aurora MySQL to invoke Amazon Comprehend on your behalf.

```
{ "Version": "2012-10-17", "Statement": [ { "Sid": "AllowAuroraToInvokeComprehendDetectSentiment", "Effect": "Allow", "Action": [ "comprehend:DetectSentiment", "comprehend:BatchDetectSentiment" ], "Resource": "*" } ] }
```

The following command performs the same operation through the AWS CLI.

```
aws iam put-role-policy --role-name role_name --policy-name policy_name
--policy-document '{ "Version": "2012-10-17", "Statement": [ { "Sid": "AllowAuroraToInvokeComprehendDetectSentiment", "Effect": "Allow", "Action": [ "comprehend:DetectSentiment", "comprehend:BatchDetectSentiment" ], "Resource": "*" } ]}'
```

### To create an IAM policy to grant access to Amazon Comprehend

1. Open the [IAM Management Console](#).
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **Comprehend**.
5. For **Actions**, choose **Detect Sentiment** and **BatchDetectSentiment**.
6. Choose **Review policy**.
7. For **Name**, enter a name for your IAM policy. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.
8. Choose **Create policy**.
9. Complete the procedure in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#).

### Creating an IAM role to access SageMaker and Amazon Comprehend

After you create the IAM policies, create an IAM role that the Aurora MySQL cluster can assume on behalf of your database users to access ML services. To create an IAM role, you can use the AWS Management

Console or the AWS CLI. To create an IAM role and attach the preceding policies to the role, follow the steps described in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 897\)](#). For more information about IAM roles, see [IAM roles](#) in the *AWS Identity and Access Management User Guide*.

You can only use a global IAM role for authentication. You can't use an IAM role associated with a database user or a session. This requirement is the same as for Aurora integration with the Lambda and Amazon S3 services.

### Associating an IAM role with an Aurora MySQL DB cluster (AWS CLI only)

#### Note

When you use the AWS Management Console, Aurora creates the IAM policy automatically. In that case, you can skip this section.

The last step is to associate the IAM role with the attached IAM policy with your Aurora MySQL DB cluster. To associate an IAM role with an Aurora DB cluster, you do two things:

1. Add the role to the list of associated roles for a DB cluster by using the AWS Management Console, the [add-role-to-db-cluster](#) AWS CLI command, or the [AddRoleToDBCluster](#) RDS API operation.
2. Set the cluster-level parameter for the related AWS ML service to the ARN for the associated IAM role. Use the `aws_default_sagemaker_role`, `aws_default_comprehend_role`, or both parameters depending on which AWS ML services you intend to use with your Aurora cluster.

Cluster-level parameters are grouped into DB cluster parameter groups. To set the preceding cluster parameters, use an existing custom DB cluster group or create a new one. To create a new DB cluster parameter group, call the `create-db-cluster-parameter-group` command from the AWS CLI, as shown following.

```
PROMPT> aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccessToExternalServices \
--db-parameter-group-family aurora-mysql5.7 --description "Allow access to Amazon S3, AWS Lambda, AWS SageMaker, and AWS Comprehend"
```

Set the appropriate cluster-level parameter or parameters and the related IAM role ARN values in your DB cluster parameter group, as shown in the following.

```
PROMPT> aws rds modify-db-cluster-parameter-group \
--db-cluster-parameter-group-name AllowAWSAccessToExternalServices \
--parameters
"ParameterName=aws_default_s3_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraS3Role,ApplyMethod=pending-reboot" \
--parameters
"ParameterName=aws_default_sagemaker_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraSageMakerRole,ApplyMethod=pending-reboot" \
--parameters
"ParameterName=aws_default_comprehend_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraComprehendRole,ApplyMethod=pending-reboot"
```

Modify the DB cluster to use the new DB cluster parameter group. Then, reboot the cluster. The following shows how.

```
PROMPT> aws rds modify-db-cluster --db-cluster-identifier your_cluster_id --db-cluster-parameter-group-nameAllowAWSAccessToExternalServices
PROMPT> aws rds failover-db-cluster --db-cluster-identifier your_cluster_id
```

When the instance has rebooted, your IAM roles are associated with your DB cluster.

## Granting SQL privileges for invoking Aurora machine learning services

After you create the required IAM policies and roles and associating the role to the Aurora MySQL DB cluster, you authorize individual database users to invoke the Aurora machine learning stored functions for SageMaker and built-in functions for Amazon Comprehend.

The database user invoking a native function must be granted a corresponding role or privilege. For Aurora MySQL version 3, you grant the `AWS_SAGEMAKER_ACCESS` role or the `AWS_COMPREHEND_ACCESS` role. For Aurora MySQL version 1 or 2, you grant the `INVOKE SAGEMAKER` or `INVOKE COMPREHEND` privilege. To grant this privilege to a user, connect to the DB instance as the administrative user, and run the following statements. Substitute the appropriate details for the database user.

Use the following statements for Aurora MySQL version 3:

```
GRANT AWS_SAGEMAKER_ACCESS TO user@domain-or-ip-address
GRANT AWS_COMPREHEND_ACCESS TO user@domain-or-ip-address
```

### Tip

When you use the role technique in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in [Role-based privilege model \(p. 664\)](#). You can also find more details in [Using Roles in the MySQL Reference Manual](#).

This only applies to the current active session. When you reconnect, you have to run the `SET ROLE` statement again to grant privileges. For more information, see [SET ROLE statement](#) in the [MySQL Reference Manual](#).

You can also use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you don't have to call the `SET ROLE` statement explicitly to activate a role. For more information, see [activate\\_all\\_roles\\_on\\_login](#) in the [MySQL Reference Manual](#).

Use the following statements for Aurora MySQL version 1 or 2:

```
GRANT INVOKE SAGEMAKER ON *.* TO user@domain-or-ip-address
GRANT INVOKE COMPREHEND ON *.* TO user@domain-or-ip-address
```

For SageMaker, user-defined functions define the parameters to be sent to the model for producing the inference and to configure the endpoint name to be invoked. You grant `EXECUTE` permission to the stored functions configured for SageMaker for each of the database users who intend to invoke the endpoint.

```
GRANT EXECUTE ON FUNCTION db1.anomaly_score TO user1@domain-or-ip-address1
GRANT EXECUTE ON FUNCTION db2.company_forecasts TO user2@domain-or-ip-address2
```

## Enabling network communication from Aurora MySQL to other AWS services

Since SageMaker and Amazon Comprehend are external AWS services, you must also configure your Aurora DB cluster to allow outbound connections to the target AWS service. For more information, see [Enabling network communication from Amazon Aurora MySQL to other AWS services \(p. 902\)](#).

You can use VPC endpoints to connect to Amazon S3. AWS PrivateLink can't be used to connect Aurora to AWS machine learning services or Amazon S3 at this time.

## Exporting data to Amazon S3 for SageMaker model training

Depending on how your team divides the machine learning tasks, you might not perform this task. If someone else provides the SageMaker model for you, you can skip this section.

To train SageMaker models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by a Jupyter SageMaker notebook instance to train your model before it is deployed. You can use the `SELECT INTO OUTFILE S3` statement to query data from an Aurora MySQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. Then the notebook instance consumes the data from the Amazon S3 bucket for training.

Aurora machine learning extends the existing `SELECT INTO OUTFILE` syntax in Aurora MySQL to export data to CSV format. The generated CSV file can be directly consumed by models that need this format for training purposes.

```
SELECT * INTO OUTFILE S3 's3_uri' [FORMAT {CSV|TEXT} [HEADER]] FROM table_name;
```

The extension supports the standard CSV format.

- Format `TEXT` is the same as the existing MySQL export format. This is the default format.
- Format `CSV` is a newly introduced format that follows the specification in [RFC-4180](#).
- If you specify the optional keyword `HEADER`, the output file contains one header line. The labels in the header line correspond to the column names from the `SELECT` statement.
- You can still use the keywords `CSV` and `HEADER` as identifiers.

The extended syntax and grammar of `SELECT INTO` is now as follows:

```
INTO OUTFILE S3 's3_uri'  
[CHARACTER SET charset_name]  
[FORMAT {CSV|TEXT} [HEADER]]  
[{FIELDS | COLUMNS}  
 [TERMINATED BY 'string']  
 [[OPTIONALLY] ENCLOSED BY 'char']  
 [ESCAPED BY 'char']  
]  
[LINES  
 [STARTING BY 'string']  
 [TERMINATED BY 'string']  
]
```

## Using SageMaker to run your own ML models

SageMaker is a fully managed machine learning service. With SageMaker, data scientists and developers can quickly and easily build and train machine learning models. Then they can directly deploy the models into a production-ready hosted environment. SageMaker provides an integrated Jupyter authoring notebook instance for easy access to your data sources. That way, you can perform exploration and analysis without managing the hardware infrastructure for servers. It also provides common machine learning algorithms that are optimized to run efficiently against extremely large datasets in a distributed environment. With native support for bring-your-own-algorithms and frameworks, SageMaker offers flexible distributed training options that adjust to your specific workflows.

Currently, Aurora machine learning supports any SageMaker endpoint that can read and write comma-separated value format, through a `ContentType` of `text/csv`. The built-in SageMaker algorithms that currently accept this format are Random Cut Forest, Linear Learner, 1P, XGBoost, and 3P. If the algorithms return multiple outputs per item, the Aurora machine learning function returns only the first item. This first item is expected to be a representative result.

Aurora machine learning always invokes SageMaker endpoints in the same AWS Region as your Aurora cluster. Therefore, for a single-region Aurora cluster, always deploy the model in the same AWS Region as your Aurora MySQL cluster.

If you are using an Aurora global database, you set up the same integration between the services for each AWS Region that's part of the global database. In particular, make sure the following conditions are satisfied for all AWS Regions in the global database:

- Configure the appropriate IAM roles for accessing external services such as SageMaker, Amazon Comprehend, or Lambda for the global database cluster in each AWS Region.
- Ensure that all AWS Regions have the same trained SageMaker models deployed with the same endpoint names. Do so before running the `CREATE FUNCTION` statement for your Aurora machine learning function in the primary AWS Region. In a global database, all `CREATE FUNCTION` statements you run in the primary AWS Region are immediately run in all the secondary regions also.

To use models deployed in SageMaker for inference, you create user-defined functions using the familiar MySQL data definition language (DDL) statements for stored functions. Each stored function represents the SageMaker endpoint hosting the model. When you define such a function, you specify the input parameters to the model, the specific SageMaker endpoint to invoke, and the return type. The function returns the inference computed by the SageMaker endpoint after applying the model to the input parameters. All Aurora machine learning stored functions return numeric types or `VARCHAR`. You can use any numeric type except `BIT`. Other types, such as `JSON`, `BLOB`, `TEXT`, and `DATE` are not allowed. Use model input parameters that are the same as the input parameters that you exported to Amazon S3 for model training.

```
CREATE FUNCTION function_name (arg1 type1, arg2 type2, ...) -- variable number of arguments
    [DEFINER = user]                                         -- same as existing MySQL
CREATE FUNCTION
    RETURNS mysql_type          -- For example, INTEGER, REAL, ...
    [SQL SECURITY { DEFINER | INVOKER } ]                      -- same as existing MySQL
CREATE FUNCTION
    ALIAS AWS_SAGEMAKER_INVOKE_ENDPOINT -- ALIAS replaces the stored function body. Only
    AWS_SAGEMAKER_INVOKE_ENDPOINT is supported for now.
    ENDPOINT NAME 'endpoint_name'                                -- default is 10,000
    [MAX_BATCH_SIZE max_batch_size];
```

This is a variation of the existing `CREATE FUNCTION` DDL statement. In the `CREATE FUNCTION` statement that defines the SageMaker function, you don't specify a function body. Instead, you specify the new keyword `ALIAS` where the function body usually goes. Currently, Aurora machine learning only supports `aws_sagemaker_invoke_endpoint` for this extended syntax. You must specify the `endpoint_name` parameter. The optional parameter `max_batch_size` restricts the maximum number of inputs processed in an actual batched request to SageMaker. An SageMaker endpoint can have different characteristics for each model. The `max_batch_size` parameter can help to avoid an error caused by inputs that are too large, or to make SageMaker return a response more quickly. The `max_batch_size` parameter affects the size of an internal buffer used for ML request processing. Specifying too large a value for `max_batch_size` might cause substantial memory overhead on your DB instance.

We recommend leaving the `MANIFEST` setting at its default value of `OFF`. Although you can use the `MANIFEST ON` option, some SageMaker features can't directly use the CSV exported with this option. The manifest format is not compatible with the expected manifest format from SageMaker.

You create a separate stored function for each of your SageMaker models. This mapping of functions to models is required because an endpoint is associated with a specific model, and each model accepts different parameters. Using SQL types for the model inputs and the model output type helps to avoid type conversion errors passing data back and forth between the AWS services. You can control who can apply the model. You can also control the runtime characteristics by specifying a parameter representing the maximum batch size.

Currently, all Aurora machine learning functions have the `NOT DETERMINISTIC` property. If you don't specify that property explicitly, Aurora sets `NOT DETERMINISTIC` automatically. This requirement is because the ML model can be changed without any notification to the database. If that happens, calls

to an Aurora machine learning function might return different results for the same input within a single transaction.

You can't use the characteristics `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, or `MODIFIES SQL DATA` in your `CREATE FUNCTION` statement.

Following is an example usage of invoking an SageMaker endpoint to detect anomalies. There is an SageMaker endpoint `random-cut-forest-model`. The corresponding model is already trained by the `random-cut-forest` algorithm. For each input, the model returns an anomaly score. This example shows the data points whose score is greater than 3 standard deviations (approximately the 99.9th percentile) from the mean score.

```
create function anomaly_score(value real) returns real
  alias aws_sagemaker_invoke_endpoint endpoint name 'random-cut-forest-model-demo';

set @score_cutoff = (select avg(anomaly_score(value)) + 3 * std(anomaly_score(value)) from
  nyc_taxi);

select *, anomaly_detection(value) score from nyc_taxi
  where anomaly_detection(value) > @score_cutoff;
```

## Character set requirement for SageMaker functions that return strings

We recommend specifying a character set of `utf8mb4` as the return type for your SageMaker functions that return string values. If that isn't practical, use a large enough string length for the return type to hold a value represented in the `utf8mb4` character set. The following example shows how to declare the `utf8mb4` character set for your function.

```
CREATE FUNCTION my_ml_func(...) RETURNS VARCHAR(5) CHARSET utf8mb4 ALIAS ...
```

Currently, each SageMaker function that returns a string uses the character set `utf8mb4` for the return value. The return value uses this character set even if your ML function declares a different character set for its return type implicitly or explicitly. If your ML function declares a different character set for the return value, the returned data might be silently truncated if you store it in a table column that isn't long enough. For example, a query with a `DISTINCT` clause creates a temporary table. Thus, the ML function result might be truncated due to the way strings are handled internally during a query.

## Using Amazon Comprehend for sentiment detection

Amazon Comprehend uses machine learning to find insights and relationships in textual data. You can use this AWS machine learning service even if you don't have any machine learning experience or expertise. Aurora machine learning uses Amazon Comprehend for sentiment analysis of text that is stored in your database. For example, using Amazon Comprehend you can analyze contact center call-in documents to detect sentiment and better understand caller-agent dynamics. You can find a further description in the post [Analyzing contact center calls](#) on the AWS Machine Learning blog.

You can also combine sentiment analysis with analysis of other information in your database using a single query. For example, you can detect the average sentiment of call-in center documents for issues that combine the following:

- Open for more than 30 days.
- About a specific product or feature.
- Made by the customers who have the greatest social media influence.

Using Amazon Comprehend from Aurora machine learning is as easy as calling a SQL function. Aurora machine learning provides two built-in Amazon Comprehend functions, `aws_comprehend_detect_sentiment()` and

`aws_comprehend_detect_sentiment()` to perform sentiment analysis through Amazon Comprehend. For each text fragment that you analyze, these functions help you to determine the sentiment and the confidence level.

```
-- Returns one of 'POSITIVE', 'NEGATIVE', 'NEUTRAL', 'MIXED'  
aws_comprehend_detect_sentiment(  
    input_text  
    ,language_code  
    [,max_batch_size] -- default is 25. should be greater than 0  
)  
  
-- Returns a double value that indicates confidence of the result of  
aws_comprehend_detect_sentiment.  
aws_comprehend_detect_sentiment_confidence(  
    input_text  
    ,language_code  
    [,max_batch_size] -- default is 25. should be greater than 0.  
)
```

The `max_batch_size` helps you to tune the performance of the Amazon Comprehend function calls. A large batch size trades off faster performance for greater memory usage on the Aurora cluster. For more information, see [Performance considerations for Aurora machine learning \(p. 937\)](#).

For information about parameters and return types for the sentiment detection functions in Amazon Comprehend, see [DetectSentiment](#)

A typical Amazon Comprehend query looks for rows where the sentiment is a certain value, with a confidence level greater than a certain number. For example, the following query shows how you can determine the average sentiment of documents in your database. The query considers only documents where the confidence of the assessment is at least 80%.

```
SELECT AVG(CASE aws_comprehend_detect_sentiment(productTable.document, 'en')  
    WHEN 'POSITIVE' THEN 1.0  
    WHEN 'NEGATIVE' THEN -1.0  
    ELSE 0.0 END) AS avg_sentiment, COUNT(*) AS total  
FROM productTable  
WHERE productTable.productCode = 1302 AND  
    aws_comprehend_detect_sentiment_confidence(productTable.document, 'en') >= 0.80;
```

#### Note

Amazon Comprehend is currently available only in some AWS Regions. To check in which AWS Regions you can use Amazon Comprehend, see [the AWS Region table page](#).

## Performance considerations for Aurora machine learning

Most of the work in an Aurora machine learning function call happens within the external ML service. This separation enables you to scale the resources for the machine learning service independent of your Aurora cluster. Within Aurora, you mostly focus on making the function calls themselves as efficient as possible.

### Query cache

The Aurora MySQL query cache doesn't work for ML functions. Aurora MySQL doesn't store query results in the query cache for any SQL statements that call ML functions.

### Batch optimization for Aurora machine learning function calls

The main Aurora machine learning performance aspect that you can influence from your Aurora cluster is the batch mode setting for calls to the Aurora machine learning stored functions. Machine learning

functions typically require substantial overhead, making it impractical to call an external service separately for each row. Aurora machine learning can minimize this overhead by combining the calls to the external Aurora machine learning service for many rows into a single batch. Aurora machine learning receives the responses for all the input rows, and delivers the responses, one row at a time, to the query as it runs. This optimization improves the throughput and latency of your Aurora queries without changing the results.

When you create an Aurora stored function that's connected to an SageMaker endpoint, you define the batch size parameter. This parameter influences how many rows are transferred for every underlying call to SageMaker. For queries that process large numbers of rows, the overhead to make a separate SageMaker call for each row can be substantial. The larger the data set processed by the stored procedure, the larger you can make the batch size.

If the batch mode optimization can be applied to an SageMaker function, you can tell by checking the query plan produced by the `EXPLAIN PLAN` statement. In this case, the `extra` column in the execution plan includes `Batched machine learning`. The following example shows a call to an SageMaker function that uses batch mode.

```
mysql> create function anomaly_score(val real) returns real alias
    aws_sagemaker_invoke_endpoint endpoint name 'my-rcf-model-20191126';
Query OK, 0 rows affected (0.01 sec)

mysql> explain select timestamp, value, anomaly_score(value) from nyc_taxi;
+-----+-----+-----+-----+-----+-----+
| id | select_type | table      | partitions | type | possible_keys | key   | key_len | ref   |
| rows | filtered | Extra          |           |       |             |        |         |        |
+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE      | nyc_taxi | NULL      | ALL  | NULL          | NULL  | NULL   | NULL  |
| 48 |    100.00 | Batched machine learning |
+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.01 sec)
```

When you call one of the built-in Amazon Comprehend functions, you can control the batch size by specifying the optional `max_batch_size` parameter. This parameter restricts the maximum number of `input_text` values processed in each batch. By sending multiple items at once, it reduces the number of round trips between Aurora and Amazon Comprehend. Limiting the batch size is useful in situations such as a query with a `LIMIT` clause. By using a small value for `max_batch_size`, you can avoid invoking Amazon Comprehend more times than you have input texts.

The batch optimization for evaluating Aurora machine learning functions applies in the following cases:

- Function calls within the select list or the `WHERE` clause of `SELECT` statements. There are some exceptions, as described following.
- Function calls in the `VALUES` list of `INSERT` and `REPLACE` statements.
- ML functions in `SET` values in `UPDATE` statements.

```
INSERT INTO MY_TABLE (col1, col2, col3) VALUES
    (ML_FUNC(1), ML_FUNC(2), ML_FUNC(3)),
    (ML_FUNC(4), ML_FUNC(5), ML_FUNC(6));
UPDATE MY_TABLE SET col1 = ML_FUNC(col2), SET col3 = ML_FUNC(col4) WHERE ...;
```

## Monitoring Aurora machine learning

To monitor the performance of Aurora machine learning batch operations, Aurora MySQL includes several global variables that you can query as follows.

```
show status like 'Aurora_ml%';
```

You can reset these status variables by using a `FLUSH STATUS` statement. Thus, all of the figures represent totals, averages, and so on, since the last time the variable was reset.

#### `Aurora_ml_logical_response_cnt`

The aggregate response count that Aurora MySQL receives from the ML services across all queries run by users of the DB instance.

#### `Aurora_ml_actual_request_cnt`

The aggregate request count that Aurora MySQL receives from the ML services across all queries run by users of the DB instance.

#### `Aurora_ml_actual_response_cnt`

The aggregate response count that Aurora MySQL receives from the ML services across all queries run by users of the DB instance.

#### `Aurora_ml_cache_hit_cnt`

The aggregate internal cache hit count that Aurora MySQL receives from the ML services across all queries run by users of the DB instance.

#### `Aurora_ml_single_request_cnt`

The aggregate count of ML functions that are evaluated by non-batch mode across all queries run by users of the DB instance.

For information about monitoring the performance of the SageMaker operations called from Aurora machine learning functions, see [Monitor Amazon SageMaker](#).

## Limitations of Aurora machine learning

The following limitations apply to Aurora machine learning.

You can't use an Aurora machine learning function for a generated-always column. The same limitation applies to any Aurora MySQL stored function. Functions aren't compatible with this binary log (binlog) format. For information about generated columns, see [the MySQL documentation](#).

The setting `--binlog-format=STATEMENT` throws an exception for calls to Aurora machine learning functions. The reason for the error is that Aurora machine learning considers all ML functions to be nondeterministic, and nondeterministic stored functions aren't compatible with this binlog format. For information about this binlog format, see [the MySQL documentation](#).

## Amazon Aurora MySQL lab mode

Aurora lab mode is used to enable Aurora features that are available in the current Aurora database version, but are not enabled by default. While Aurora lab mode features are not recommended for use in production DB clusters, you can use Aurora lab mode to enable these features for DB clusters in your development and test environments. For more information about Aurora features available when Aurora lab mode is enabled, see [Aurora lab mode features \(p. 940\)](#).

The `aurora_lab_mode` parameter is an instance-level parameter that is in the default parameter group. The parameter is set to 0 (disabled) in the default parameter group. To enable Aurora lab mode, create a custom parameter group, set the `aurora_lab_mode` parameter to 1 (enabled) in the custom parameter group, and modify one or more DB instances in your Aurora cluster to use the custom parameter group. Then connect to the appropriate instance endpoint to try the lab mode features. For information on modifying a DB parameter group, see [Modifying parameters in a DB](#)

parameter group (p. 231). For information on parameter groups and Amazon Aurora, see [Aurora MySQL configuration parameters \(p. 949\)](#).

## Aurora lab mode features

The following table lists the Aurora features currently available when Aurora lab mode is enabled. You must enable Aurora lab mode before any of these features can be used.

Feature	Description
Scan Batching	Aurora MySQL scan batching speeds up in-memory, scan-oriented queries significantly. The feature boosts the performance of table full scans, index full scans, and index range scans by batch processing.
Hash Joins	This feature can improve query performance when you need to join a large amount of data by using an equijoin. It requires lab mode in Aurora MySQL version 1. You can use this feature without lab mode in Aurora MySQL version 2. For more information about using this feature, see <a href="#">Optimizing large Aurora MySQL join queries with hash joins (p. 945)</a> .
Fast DDL	This feature allows you to run an <code>ALTER TABLE <i>tbl_name</i> ADD COLUMN <i>col_name column_definition</i></code> operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. Since it does not consume temporary storage for a table copy, it makes DDL statements practical even for large tables on small instance classes. Fast DDL is currently only supported for adding a nullable column, without a default value, at the end of a table. For more information about using this feature, see <a href="#">Altering tables in Amazon Aurora using fast DDL (p. 741)</a> .

## Best practices with Amazon Aurora MySQL

This topic includes information on best practices and options for using or migrating data to an Amazon Aurora MySQL DB cluster. The information in this topic summarizes and reiterates some of the guidelines and procedures that you can find in [Managing an Amazon Aurora DB cluster \(p. 243\)](#).

### Contents

- [Determining which DB instance you are connected to \(p. 941\)](#)
- [Best practices for Aurora MySQL performance and scaling \(p. 941\)](#)
  - [Using T instance classes for development and testing \(p. 941\)](#)
  - [Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch \(p. 943\)](#)
    - [Enabling asynchronous key prefetch \(p. 943\)](#)
    - [Optimizing queries for asynchronous key prefetch \(p. 944\)](#)

  - Enabling hash joins (p. 945)
  - Optimizing queries for hash joins (p. 946)
- Using Amazon Aurora to scale reads for your MySQL database (p. 947)
- Best practices for Aurora MySQL high availability (p. 947)
  - Using Amazon Aurora for Disaster Recovery with your MySQL databases (p. 947)
  - Migrating from MySQL to Amazon Aurora MySQL with reduced downtime (p. 948)
- Recommendations for MySQL features (p. 948)
  - Using multithreaded replication in Aurora MySQL version 3 (p. 948)
  - Invoking AWS Lambda functions using native MySQL functions (p. 948)
  - Avoiding XA transactions with Amazon Aurora MySQL (p. 949)
  - Keeping foreign keys turned on during DML statements (p. 949)

## Determining which DB instance you are connected to

To determine which DB instance in an Aurora MySQL DB cluster a connection is connected to, check the `innodb_read_only` global variable, as shown in the following example.

```
SHOW GLOBAL VARIABLES LIKE 'innodb_read_only';
```

The `innodb_read_only` variable is set to `ON` if you are connected to a reader DB instance. This setting is `OFF` if you are connected to a writer DB instance, such as primary instance in a provisioned cluster.

This approach can be helpful if you want to add logic to your application code to balance the workload or to ensure that a write operation is using the correct connection. This technique only applies to Aurora clusters using single-master replication. For multi-master clusters, all the DB instances have the setting `innodb_read_only=OFF`.

## Best practices for Aurora MySQL performance and scaling

You can apply the following best practices to improve the performance and scalability of your Aurora MySQL clusters.

### Topics

- Using T instance classes for development and testing (p. 941)
- Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 943)
- Optimizing large Aurora MySQL join queries with hash joins (p. 945)
- Using Amazon Aurora to scale reads for your MySQL database (p. 947)

## Using T instance classes for development and testing

Amazon Aurora MySQL instances that use the `db.t2`, `db.t3`, or `db.t4g` DB instance classes are best suited for applications that do not support a high workload for an extended amount of time. The T instances are designed to provide moderate baseline performance and the capability to burst to significantly higher performance as required by your workload. They are intended for workloads that don't use the full CPU often or consistently, but occasionally need to burst. We recommend only using the T DB instance classes for development and test servers, or other non-production servers. For more details on the T instance classes, see [Burstable performance instances](#).

If your Aurora cluster is larger than 40 TB, don't use the T instance classes. When your database has a large volume of data, the memory overhead for managing schema objects can exceed the capacity of a T instance.

Don't enable the MySQL Performance Schema on Amazon Aurora MySQL T instances. If the Performance Schema is enabled, the instance might run out of memory.

**Tip**

If your database is sometimes idle but at other times has a substantial workload, you can use Aurora Serverless v2 as an alternative to T instances. With Aurora Serverless v2, you define a capacity range and Aurora automatically scales your database up or down depending on the current workload. For usage details, see [Using Aurora Serverless v2 \(p. 1482\)](#). For the database engine versions that you can use with Aurora Serverless v2, see [Requirements for Aurora Serverless v2 \(p. 1490\)](#).

When you use a T instance as a DB instance in an Aurora MySQL DB cluster, we recommend the following:

- If you use a T instance as a DB instance class in your DB cluster, use the same DB instance class for all instances in your DB cluster. For example, if you use db.t2.medium for your writer instance, then we recommend that you use db.t2.medium for your reader instances also.
- Don't adjust any memory-related configuration settings, such as `innodb_buffer_pool_size`. Aurora uses a highly tuned set of default values for memory buffers on T instances. These special defaults are needed for Aurora to run on memory-constrained instances. If you change any memory-related settings on a T instance, you are much more likely to encounter out-of-memory conditions, even if your change is intended to increase buffer sizes.
- Monitor your CPU Credit Balance (`CPUCreditBalance`) to ensure that it is at a sustainable level. That is, CPU credits are being accumulated at the same rate as they are being used.

When you have exhausted the CPU credits for an instance, you see an immediate drop in the available CPU and an increase in the read and write latency for the instance. This situation results in a severe decrease in the overall performance of the instance.

If your CPU credit balance is not at a sustainable level, then we recommend that you modify your DB instance to use a one of the supported R DB instance classes (scale compute).

For more information on monitoring metrics, see [Viewing metrics in the Amazon RDS console \(p. 449\)](#).

- For your Aurora MySQL DB clusters using single-master replication, monitor the replica lag (`AuroraReplicaLag`) between the writer instance and the reader instances.

If a reader instance runs out of CPU credits before the writer instance does, the resulting lag can cause the reader instance to restart frequently. This result is common when an application has a heavy load of read operations distributed among reader instances, at the same time that the writer instance has a minimal load of write operations.

If you see a sustained increase in replica lag, make sure that your CPU credit balance for the reader instances in your DB cluster is not being exhausted.

If your CPU credit balance is not at a sustainable level, then we recommend that you modify your DB instance to use one of the supported R DB instance classes (scale compute).

- Keep the number of inserts per transaction below 1 million for DB clusters that have binary logging enabled.

If the DB cluster parameter group for your DB cluster has the `binlog_format` parameter set to a value other than OFF, then your DB cluster might experience out-of-memory conditions if the DB cluster receives transactions that contain over 1 million rows to insert. You can monitor the freeable memory (`FreeableMemory`) metric to determine if your DB cluster is running out of available memory. You then check the write operations (`volumeWriteIOPS`) metric to see if a writer instance is

receiving a heavy load of write operations. If this is the case, then we recommend that you update your application to limit the number of inserts in a transaction to less than 1 million. Alternatively, you can modify your instance to use one of the supported R DB instance classes (scale compute).

## Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch

### Note

The asynchronous key prefetch (AKP) feature is available for Amazon Aurora MySQL version 1.15 and later. For more information about Aurora MySQL versions, see [Database engine updates for Amazon Aurora MySQL \(p. 990\)](#).

Amazon Aurora can use AKP to improve the performance of queries that join tables across indexes. This feature improves performance by anticipating the rows needed to run queries in which a JOIN query requires use of the Batched Key Access (BKA) Join algorithm and Multi-Range Read (MRR) optimization features. For more information about BKA and MRR, see [Block nested-loop and batched key access joins](#) and [Multi-range read optimization](#) in the MySQL documentation.

To take advantage of the AKP feature, a query must use both BKA and MRR. Typically, such a query occurs when the JOIN clause of a query uses a secondary index, but also needs some columns from the primary index. For example, you can use AKP when a JOIN clause represents an equijoin on index values between a small outer and large inner table, and the index is highly selective on the larger table. AKP works in concert with BKA and MRR to perform a secondary to primary index lookup during the evaluation of the JOIN clause. AKP identifies the rows required to run the query during the evaluation of the JOIN clause. It then uses a background thread to asynchronously load the pages containing those rows into memory before running the query.

### Enabling asynchronous key prefetch

You can enable the AKP feature by setting `aurora_use_key_prefetch`, a MySQL server variable, to `on`. By default, this value is set to `on`. However, AKP cannot be enabled until you also enable the BKA Join algorithm and disable cost-based MRR functionality. To do so, you must set the following values for `optimizer_switch`, a MySQL server variable:

- Set `batched_key_access` to `on`. This value controls the use of the BKA Join algorithm. By default, this value is set to `off`.
- Set `mrr_cost_based` to `off`. This value controls the use of cost-based MRR functionality. By default, this value is set to `on`.

Currently, you can set these values only at the session level. The following example illustrates how to set these values to enable AKP for the current session by executing SET statements.

```
mysql> set @@session.aurora_use_key_prefetch=on;
mysql> set @@session.optimizer_switch='batched_key_access=on,mrr_cost_based=off';
```

Similarly, you can use SET statements to disable AKP and the BKA Join algorithm and re-enable cost-based MRR functionality for the current session, as shown in the following example.

```
mysql> set @@session.aurora_use_key_prefetch=off;
mysql> set @@session.optimizer_switch='batched_key_access=off,mrr_cost_based=on';
```

For more information about the `batched_key_access` and `mrr_cost_based` optimizer switches, see [Switchable optimizations](#) in the MySQL documentation.

## Optimizing queries for asynchronous key prefetch

You can confirm whether a query can take advantage of the AKP feature. To do so, use the `EXPLAIN` statement to profile the query before running it. The `EXPLAIN` statement provides information about the execution plan to use for a specified query.

In the output for the `EXPLAIN` statement, the `Extra` column describes additional information included with the execution plan. If the AKP feature applies to a table used in the query, this column includes one of the following values:

- Using Key Prefetching
- Using join buffer (Batched Key Access with Key Prefetching)

The following example shows the use of `EXPLAIN` to view the execution plan for a query that can take advantage of AKP.

```
mysql> explain select sql_no_cache
->     ps_partkey,
->     sum(ps_supplycost * ps_availqty) as value
-> from
->     partsupp,
->     supplier,
->     nation
-> where
->     ps_suppkey = s_suppkey
->     and s_nationkey = n_nationkey
->     and n_name = 'ETHIOPIA'
-> group by
->     ps_partkey having
->         sum(ps_supplycost * ps_availqty) > (
->             select
->                 sum(ps_supplycost * ps_availqty) * 0.0000003333
->             from
->                 partsupp,
->                 supplier,
->                 nation
->             where
->                 ps_suppkey = s_suppkey
->                 and s_nationkey = n_nationkey
->                 and n_name = 'ETHIOPIA'
->             )
-> order by
->     value desc;

```

For more information about the `EXPLAIN` output format, see [Extended EXPLAIN output format](#) in the MySQL product documentation.

**Note**

For MySQL 5.6-compatible and older 5.7-compatible versions, you use the `EXPLAIN` statement with the `EXTENDED` keyword. This keyword has been deprecated in MySQL 5.7 and 8.0.

For more information about the extended `EXPLAIN` output format in MySQL 5.6, see [Extended EXPLAIN output format](#) in the MySQL product documentation.

## Optimizing large Aurora MySQL join queries with hash joins

When you need to join a large amount of data by using an equijoin, a hash join can improve query performance. You can enable hash joins for Aurora MySQL.

A hash join column can be any complex expression. In a hash join column, you can compare across data types in the following ways:

- You can compare anything across the category of precise numeric data types, such as `int`, `bigint`, `numeric`, and `bit`.
- You can compare anything across the category of approximate numeric data types, such as `float` and `double`.
- You can compare items across string types if the string types have the same character set and collation.
- You can compare items with date and timestamp data types if the types are the same.

**Note**

You can't compare data types in different categories.

The following restrictions apply to hash joins for Aurora MySQL:

- Left-right outer joins aren't supported for Aurora MySQL versions 1 and 2, but are supported for version 3.
- Semijoins such as subqueries aren't supported, unless the subqueries are materialized first.
- Multiple-table updates or deletes aren't supported.

**Note**

Single-table updates or deletes are supported.

- BLOB and spatial data type columns can't be join columns in a hash join.

## Enabling hash joins

To enable hash joins, set the MySQL server variable `optimizer_switch` to `hash_join=on` (Aurora MySQL version 1 and 2) or `block_nested_loop=on` (Aurora MySQL version 3). Hash joins are turned

on by default in Aurora MySQL version 3. This optimization is turned off by default in Aurora MySQL version 1 and 2. The following example illustrates how to enable hash joins. You can issue the statement `select @@optimizer_switch` first to see what other settings are present in the `SET` parameter string. Updating one setting in the `optimizer_switch` parameter doesn't erase or modify the other settings.

```
For Aurora MySQL version 1 and 2:  
mysql> SET optimizer_switch='hash_join=on';  
  
For Aurora MySQL version 3:  
mysql> SET optimizer_switch='block_nested_loop=on';
```

**Note**

For Aurora MySQL version 3, hash join support is available in all minor versions and is turned on by default.

For Aurora MySQL version 2, hash join support is available in version 2.06 and higher. In Aurora MySQL version 2, the hash join feature is always controlled by the `optimizer_switch` value. Prior to Aurora MySQL version 1.22, the way to enable hash joins in Aurora MySQL version 1 is by enabling the `aurora_lab_mode` session-level setting. In those Aurora MySQL versions, the `optimizer_switch` setting for hash joins is enabled by default and you only need to enable `aurora_lab_mode`.

With this setting, the optimizer chooses to use a hash join based on cost, query characteristics, and resource availability. If the cost estimation is incorrect, you can force the optimizer to choose a hash join. You do so by setting `hash_join_cost_based`, a MySQL server variable, to `off`. The following example illustrates how to force the optimizer to choose a hash join.

```
mysql> SET optimizer_switch='hash_join_cost_based=off';
```

**Note**

This setting overrides the decisions of the cost-based optimizer. While the setting can be useful for testing and development, we recommend that you not use it in production.

## Optimizing queries for hash joins

To find out whether a query can take advantage of a hash join, use the `EXPLAIN` statement to profile the query first. The `EXPLAIN` statement provides information about the execution plan to use for a specified query.

In the output for the `EXPLAIN` statement, the `Extra` column describes additional information included with the execution plan. If a hash join applies to the tables used in the query, this column includes values similar to the following:

- Using where; Using join buffer (Hash Join Outer table `table1_name`)
- Using where; Using join buffer (Hash Join Inner table `table2_name`)

The following example shows the use of `EXPLAIN` to view the execution plan for a hash join query.

```
mysql> explain SELECT sql_no_cache * FROM hj_small, hj_big, hj_big2  
-> WHERE hj_small.col1 = hj_big.col1 and hj_big.col1=hj_big2.col1 ORDER BY 1;  
+-----+-----+-----+-----+-----+-----+-----+-----+-----+  
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra  
|-----+-----+-----+-----+-----+-----+-----+-----+-----+  
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
```

```
| 1 | SIMPLE      | hj_small | ALL  | NULL          | NULL | NULL | NULL | 6 | Using
temporary; Using filesort
| 1 | SIMPLE      | hj_big   | ALL  | NULL          | NULL | NULL | NULL | 10 | Using
where; Using join buffer (Hash Join Outer table hj_big) |
| 1 | SIMPLE      | hj_big2 | ALL  | NULL          | NULL | NULL | NULL | 15 | Using
where; Using join buffer (Hash Join Inner table hj_big2) |
+---+-----+-----+-----+-----+-----+-----+-----+
+-----+
3 rows in set (0.04 sec)
```

In the output, the `Hash Join Inner table` is the table used to build hash table, and the `Hash Join Outer table` is the table that is used to probe the hash table.

For more information about the extended EXPLAIN output format, see [Extended EXPLAIN output format in the MySQL product documentation](#).

In Aurora MySQL 2.08 and higher, you can use SQL hints to influence whether a query uses hash join or not, and which tables to use for the build and probe sides of the join. For details, see [Aurora MySQL hints \(p. 982\)](#).

## Using Amazon Aurora to scale reads for your MySQL database

You can use Amazon Aurora with your MySQL DB instance to take advantage of the read scaling capabilities of Amazon Aurora and expand the read workload for your MySQL DB instance. To use Aurora to read scale your MySQL DB instance, create an Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance. Then connect to the Aurora MySQL cluster to process the read queries. The source database can be an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS. For more information, see [Using Amazon Aurora to scale reads for your MySQL database \(p. 854\)](#).

## Best practices for Aurora MySQL high availability

You can apply the following best practices to improve the availability of your Aurora MySQL clusters.

### Topics

- [Using Amazon Aurora for Disaster Recovery with your MySQL databases \(p. 947\)](#)
- [Migrating from MySQL to Amazon Aurora MySQL with reduced downtime \(p. 948\)](#)

## Using Amazon Aurora for Disaster Recovery with your MySQL databases

You can use Amazon Aurora with your MySQL DB instance to create an offsite backup for disaster recovery. To use Aurora for disaster recovery of your MySQL DB instance, create an Amazon Aurora DB cluster and make it a read replica of your MySQL DB instance. This applies to an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS.

### Important

When you set up replication between a MySQL DB instance and an Amazon Aurora MySQL DB cluster, you should monitor the replication to ensure that it remains healthy and repair it if necessary.

For instructions on how to create an Amazon Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance, follow the procedure in [Using Amazon Aurora to scale reads for your MySQL database \(p. 947\)](#).

For more information on disaster recovery models, see [How to choose the best disaster recovery option for your Amazon Aurora MySQL cluster](#).

## Migrating from MySQL to Amazon Aurora MySQL with reduced downtime

When importing data from a MySQL database that supports a live application to an Amazon Aurora MySQL DB cluster, you might want to reduce the time that service is interrupted while you migrate. To do so, you can use the procedure documented in [Importing data to a MySQL or MariaDB DB instance with reduced downtime](#) in the *Amazon Relational Database Service User Guide*. This procedure can especially help if you are working with a very large database. You can use the procedure to reduce the cost of the import by minimizing the amount of data that is passed across the network to AWS.

The procedure lists steps to transfer a copy of your database data to an Amazon EC2 instance and import the data into a new RDS for MySQL DB instance. Because Amazon Aurora is compatible with MySQL, you can instead use an Amazon Aurora DB cluster for the target Amazon RDS MySQL DB instance.

## Recommendations for MySQL features

The following features are available in Aurora MySQL for MySQL compatibility. However, they have performance, scalability, stability, or compatibility issues in the Aurora environment. Thus, we recommend that you follow certain guidelines in your use of these features. For example, we recommend that you don't use certain features for production Aurora deployments.

### Topics

- [Using multithreaded replication in Aurora MySQL version 3 \(p. 948\)](#)
- [Invoking AWS Lambda functions using native MySQL functions \(p. 948\)](#)
- [Avoiding XA transactions with Amazon Aurora MySQL \(p. 949\)](#)
- [Keeping foreign keys turned on during DML statements \(p. 949\)](#)

## Using multithreaded replication in Aurora MySQL version 3

By default, Aurora uses single-threaded replication when an Aurora MySQL DB cluster is used as a read replica for binary log replication.

Although Aurora MySQL doesn't prohibit multithreaded replication, this feature is only supported in Aurora MySQL version 3 and higher.

Aurora MySQL version 1 and 2 inherited several issues regarding multithreaded replication from MySQL. For those versions, we recommend that you don't use multithreaded replication in production.

If you do use multithreaded replication, we recommend that you test any use thoroughly.

For more information about using replication in Amazon Aurora, see [Replication with Amazon Aurora \(p. 73\)](#). For information about multithreaded replication in Aurora MySQL version 3, see [Multithreaded binary log replication \(Aurora MySQL version 3 and higher\) \(p. 857\)](#).

## Invoking AWS Lambda functions using native MySQL functions

If you are using Amazon Aurora version 1.16 or later, we recommend using the native MySQL functions `lambda_sync` and `lambda_async` to invoke Lambda functions.

If you are using the deprecated `mysql.lambda_async` procedure, we recommend that you wrap calls to the `mysql.lambda_async` procedure in a stored procedure. You can call this stored procedure from different sources, such as triggers or client code. This approach can help to avoid impedance mismatch issues and make it easier for your database programmers to invoke Lambda functions.

For more information on invoking Lambda functions from Amazon Aurora, see [Invoking a Lambda function from an Amazon Aurora MySQL DB cluster \(p. 917\)](#).

## Avoiding XA transactions with Amazon Aurora MySQL

We recommend that you don't use eXtended Architecture (XA) transactions with Aurora MySQL, because they can cause long recovery times if the XA was in the `PREPARED` state. If you must use XA transactions with Aurora MySQL, follow these best practices:

- Don't leave an XA transaction open in the `PREPARED` state.
- Keep XA transactions as small as possible.

For more information about using XA transactions with MySQL, see [XA transactions](#) in the MySQL documentation.

## Keeping foreign keys turned on during DML statements

We strongly recommend that you don't run any data definition language (DDL) statements when the `foreign_key_checks` variable is set to 0 (off).

If you need to insert or update rows that require a transient violation of foreign keys, follow these steps:

1. Set `foreign_key_checks` to 0.
2. Make your data manipulation language (DML) changes.
3. Make sure that your completed changes don't violate any foreign key constraints.
4. Set `foreign_key_checks` to 1 (on).

In addition, follow these other best practices for foreign key constraints:

- Make sure that your client applications don't set the `foreign_key_checks` variable to 0 as a part of the `init_connect` variable.
- If a restore from a logical backup such as `mysqldump` fails or is incomplete, make sure that `foreign_key_checks` is set to 1 before starting any other operations in the same session. A logical backup sets `foreign_key_checks` to 0 when it starts.

## Amazon Aurora MySQL reference

This reference includes information about Aurora MySQL parameters, status variables, and general SQL extensions or differences from the community MySQL database engine.

### Topics

- [Aurora MySQL configuration parameters \(p. 949\)](#)
- [MySQL parameters that don't apply to Aurora MySQL \(p. 969\)](#)
- [MySQL status variables that don't apply to Aurora MySQL \(p. 970\)](#)
- [Aurora MySQL wait events \(p. 971\)](#)
- [Aurora MySQL thread states \(p. 975\)](#)
- [Aurora MySQL isolation levels \(p. 978\)](#)
- [Aurora MySQL hints \(p. 982\)](#)
- [Aurora MySQL stored procedures \(p. 984\)](#)

## Aurora MySQL configuration parameters

You manage your Amazon Aurora MySQL DB cluster in the same way that you manage other Amazon RDS DB instances, by using parameters in a DB parameter group. Amazon Aurora differs from other DB engines in that you have a DB cluster that contains multiple DB instances. As a result, some of the parameters that you use to manage your Aurora MySQL DB cluster apply to the entire cluster. Other parameters apply only to a particular DB instance in the DB cluster.

To manage cluster-level parameters, you use DB cluster parameter groups. To manage instance-level parameters, you use DB parameter groups. Each DB instance in an Aurora MySQL DB cluster is compatible with the MySQL database engine. However, you apply some of the MySQL database engine parameters at the cluster level, and you manage these parameters using DB cluster parameter groups. You can't find cluster-level parameters in the DB parameter group for an instance in an Aurora DB cluster. A list of cluster-level parameters appears later in this topic.

You can manage both cluster-level and instance-level parameters using the AWS Management Console, the AWS CLI, or the Amazon RDS API. You use separate commands for managing cluster-level parameters and instance-level parameters. For example, you can use the [modify-db-cluster-parameter-group](#) CLI command to manage cluster-level parameters in a DB cluster parameter group. You can use the [modify-db-parameter-group](#) CLI command to manage instance-level parameters in a DB parameter group for a DB instance in a DB cluster.

You can view both cluster-level and instance-level parameters in the console, or by using the CLI or RDS API. For example, you can use the [describe-db-cluster-parameters](#) AWS CLI command to view cluster-level parameters in a DB cluster parameter group. You can use the [describe-db-parameters](#) CLI command to view instance-level parameters in a DB parameter group for a DB instance in a DB cluster.

**Note**

Each [default parameter group](#) (p. 215) contains the default values for all parameters in the parameter group. If the parameter has "engine default" for this value, see the version-specific MySQL or PostgreSQL documentation for the actual default value.

For more information on DB parameter groups, see [Working with parameter groups](#) (p. 215). For rules and restrictions for Aurora Serverless clusters, see [Parameter groups for Aurora Serverless v1](#) (p. 1554).

**Topics**

- [Cluster-level parameters](#) (p. 950)
- [Instance-level parameters](#) (p. 956)

## Cluster-level parameters

The following table shows all of the parameters that apply to the entire Aurora MySQL DB cluster.

Parameter name	Modifiable	Notes
aurora_binlog_read_buffer_size	Yes	Only affects clusters that use binary log (binlog) replication. For information about binlog replication, see <a href="#">Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)</a> (p. 841). Removed from Aurora MySQL version 3.
aurora_binlog_replication_max_yield_time	Yes	Only affects clusters that use binary log (binlog) replication. For information about binlog replication, see <a href="#">Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)</a> (p. 841).

Parameter name	Modifiable	Notes
aurora_binlog_use_large_read_buffer	Yes	Only affects clusters that use binary log (binlog) replication. For information about binlog replication, see <a href="#">Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 841)</a> . Removed from Aurora MySQL version 3.
aurora_enable_replica_log_compression	Yes	For more information, see <a href="#">Performance considerations for Amazon Aurora MySQL replication (p. 828)</a> . Doesn't apply to clusters that are part of an Aurora global database. Removed from Aurora MySQL version 3.
aurora_enable_repl_bin_log_filtering	Yes	For more information, see <a href="#">Performance considerations for Amazon Aurora MySQL replication (p. 828)</a> . Doesn't apply to clusters that are part of an Aurora global database. Removed from Aurora MySQL version 3.
aurora_enable_staggered_replica_restart	Yes	This setting is available in Aurora MySQL versions 1 and 3, but it isn't used.
aurora_enable_zdr	Yes	This setting is turned on by default in Aurora MySQL 2.10 and higher. For more information, see <a href="#">Zero-downtime restart (ZDR) for Amazon Aurora MySQL (p. 829)</a> .
aurora_load_from_s3_role	Yes	For more information, see <a href="#">Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 903)</a> . Currently not available in Aurora MySQL version 3. Use <code>aws_default_s3_role</code> .
aurora_select_into_s3_role	Yes	For more information, see <a href="#">Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 911)</a> . Currently not available in Aurora MySQL version 3. Use <code>aws_default_s3_role</code> .
auto_increment_increment	Yes	
auto_increment_offset	Yes	
aws_default_lambda_role	Yes	For more information, see <a href="#">Invoking a Lambda function from an Amazon Aurora MySQL DB cluster (p. 917)</a> .
aws_default_s3_role	Yes	

Parameter name	Modifiable	Notes
binlog_checksum	Yes	The AWS CLI and RDS API report a value of <code>None</code> if this parameter isn't set. In that case, Aurora MySQL uses the engine default value, which is <code>CRC32</code> . This is different than the explicit setting of <code>NONE</code> , which turns off the checksum. For a bug fix related to this parameter, see <a href="#">Aurora MySQL database engine updates 2020-09-02 (version 1.23.0)</a> and <a href="#">Aurora MySQL database engine updates 2020-03-05 (version 1.22.2)</a> in the <i>Release Notes for Aurora MySQL</i> .
binlog-do-db	Yes	This parameter applies to Aurora MySQL version 3 and higher.
binlog_format	Yes	For more information, see <a href="#">Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 841)</a> .
binlog_group_commit_sync_delay	Yes	This parameter applies to Aurora MySQL version 3 and higher.
binlog_group_commit_sync_no_delay_Yes_nt	Yes	This parameter applies to Aurora MySQL version 3 and higher.
binlog-ignore-db	Yes	This parameter applies to Aurora MySQL version 3 and higher.
binlog_row_image	No	
binlog_row_metadata	Yes	This parameter applies to Aurora MySQL version 3 and higher.
binlog_row_value_options	Yes	This parameter applies to Aurora MySQL version 3 and higher.
binlog_rows_query_log_events	Yes	
binlog_transaction_compression	Yes	This parameter applies to Aurora MySQL version 3 and higher.
binlog_transaction_compression_level_Yes_zstd	Yes	This parameter applies to Aurora MySQL version 3 and higher.
binlog_transaction_dependency_history_size_Yes_size	Yes	This parameter applies to Aurora MySQL version 3 and higher.
binlog_transaction_dependency_tracking_Yes_ng	Yes	This parameter applies to Aurora MySQL version 3 and higher.
character-set-client-handshake	Yes	
character_set_client	Yes	
character_set_connection	Yes	

Parameter name	Modifiable	Notes
character_set_database	Yes	
character_set_filesystem	Yes	
character_set_results	Yes	
character_set_server	Yes	
collation_connection	Yes	
collation_server	Yes	
completion_type	Yes	
default_storage_engine	No	Aurora MySQL clusters use the InnoDB storage engine for all of your data.
enforce_gtid_consistency	Sometimes	Modifiable in Aurora MySQL version 2.04 and later.
event_scheduler	Yes	Indicates the status of the Event Scheduler.  Modifiable only at the cluster level in Aurora MySQL version 3.
gtid-mode	Sometimes	Modifiable in Aurora MySQL version 2.04 and later.
innodb_autoinc_lock_mode	Yes	
innodb_checksums	No	Removed from Aurora MySQL version 3.
innodb_cmp_per_index_enabled	Yes	
innodb_commit_concurrency	Yes	
innodb_data_home_dir	No	Aurora MySQL uses managed instances where you don't access the file system directly.
innodb_deadlock_detect	Yes	This option is used to disable deadlock detection on Aurora MySQL version 3.  On high-concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. Consult the MySQL documentation for more information on this parameter.
innodb_file_per_table	Yes	
innodb_flush_log_at_trx_commit	Yes (Aurora MySQL version 1 and 2), No (Aurora MySQL version 3)	For Aurora MySQL version 3, Aurora always uses the default value of 1.

Parameter name	Modifiable	Notes
innodb_ft_max_token_size	Yes	
innodb_ft_min_token_size	Yes	
innodb_ft_num_word_optimize	Yes	
innodb_ft_sort_pll_degree	Yes	
innodb_online_alter_log_max_size	Yes	
innodb_optimize_fulltext_only	Yes	
innodb_page_size	No	
innodb_purge_batch_size	Yes	
innodb_purge_threads	Yes	
innodb_rollback_on_timeout	Yes	
innodb_rollback_segments	Yes	
innodb_spin_wait_delay	Yes	
innodb_strict_mode	Yes	
innodb_support_xa	Yes	Removed from Aurora MySQL version 3.
innodb_sync_array_size	Yes	
innodb_sync_spin_loops	Yes	
innodb_table_locks	Yes	
innodb_undo_directory	No	Aurora MySQL uses managed instances where you don't access the file system directly.
innodb_undo_logs	Yes	Removed from Aurora MySQL version 3.
innodb_undo_tablespaces	No	Removed from Aurora MySQL version 3.
internal_tmp_mem_storage_engine	Yes	This parameter applies to Aurora MySQL version 3 and higher.
lc_time_names	Yes	

Parameter name	Modifiable	Notes
<code>lower_case_table_names</code>	Yes (Aurora MySQL version 1 and 2), only at cluster creation time (Aurora MySQL version 3)	In Aurora MySQL version 2.10 and higher 2.x versions, make sure to reboot all reader instances after changing this setting and rebooting the writer instance. For details, see <a href="#">Rebooting an Aurora MySQL cluster (version 2.10 and higher) (p. 330)</a> . In Aurora MySQL version 3, the value of this parameter is set permanently at the time the cluster is created. If you use a nondefault value for this option, set up your Aurora MySQL version 3 custom parameter group before upgrading, and specify the parameter group during the snapshot restore operation that creates the version 3 cluster.
<code>master-info-repository</code>	Yes	Removed from Aurora MySQL version 3.
<code>master_verify_checksum</code>	Yes	Aurora MySQL version 1 and 2. Use <code>source_verify_checksum</code> in Aurora MySQL version 3.
<code>partial_revokes</code>	No	This parameter applies to Aurora MySQL version 3 and higher.
<code>relay-log-space-limit</code>	Yes	This parameter applies to Aurora MySQL version 3 and higher.
<code>replica_preserve_commit_order</code>	Yes	This parameter applies to Aurora MySQL version 3 and higher.
<code>replica_transaction_retries</code>	Yes	This parameter applies to Aurora MySQL version 3 and higher.
<code>replicate-do-db</code>	Yes	This parameter applies to Aurora MySQL version 3 and higher.
<code>replicate-do-table</code>	Yes	This parameter applies to Aurora MySQL version 3 and higher.
<code>replicate-ignore-db</code>	Yes	This parameter applies to Aurora MySQL version 3 and higher.
<code>replicate-ignore-table</code>	Yes	This parameter applies to Aurora MySQL version 3 and higher.
<code>replicate-wild-do-table</code>	Yes	This parameter applies to Aurora MySQL version 3 and higher.
<code>replicate-wild-ignore-table</code>	Yes	This parameter applies to Aurora MySQL version 3 and higher.
<code>require_secure_transport</code>	Yes	For more information, see <a href="#">Using SSL/TLS with Aurora MySQL DB clusters (p. 683)</a> .
<code>rpl_read_size</code>	Yes	This parameter applies to Aurora MySQL version 3 and higher.

Parameter name	Modifiable	Notes
server_audit_events	Yes	
server_audit_excl_users	Yes	
server_audit_incl_users	Yes	
server_audit_logging	Yes	For instructions on uploading the logs to Amazon CloudWatch Logs, see <a href="#">Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs (p. 924)</a> .
server_id	No	
skip-character-set-client-handshake	Yes	
skip_name_resolve	No	
slave-skip-errors	Yes	Only applies to Aurora MySQL version 2 clusters, with MySQL 5.7 compatibility.
source_verify_checksum	Yes	Aurora MySQL version 3 and higher
sync_frm	Yes	Removed from Aurora MySQL version 3.
time_zone	Yes	
tls_version	Yes	For more information, see <a href="#">TLS versions for Aurora MySQL (p. 684)</a> .

## Instance-level parameters

The following table shows all of the parameters that apply to a specific DB instance in an Aurora MySQL DB cluster.

Parameter name	Modifiable	Notes
activate_all_roles_on_login	Yes	This parameter applies to Aurora MySQL version 3 and higher.
allow-suspicious-udfs	No	
aurora_lab_mode	Yes	For more information, see <a href="#">Amazon Aurora MySQL lab mode (p. 939)</a> . Removed from Aurora MySQL version 3.
aurora_oom_response	Yes	This parameter only applies to Aurora MySQL version 1.18 and higher. It isn't used in Aurora MySQL version 2 or 3. For more information, see <a href="#">Amazon Aurora MySQL out of memory issues (p. 1765)</a> .
aurora_parallel_query	Yes	Set to ON to turn on parallel query in Aurora MySQL versions 1.23 and 2.09 or higher. The old aurora_pq parameter isn't used in these versions.

Parameter name	Modifiable	Notes
		For more information, see <a href="#">Working with parallel query for Amazon Aurora MySQL (p. 790)</a> .
aurora_pq	Yes	Set to OFF to turn off parallel query for specific DB instances in Aurora MySQL versions before 1.23 and 2.09. In 1.23 and 2.09 or higher, turn parallel query on and off with <code>aurora_parallel_query</code> instead. For more information, see <a href="#">Working with parallel query for Amazon Aurora MySQL (p. 790)</a> .
autocommit	Yes	
automatic_sp_privileges	Yes	
back_log	Yes	
basedir	No	Aurora MySQL uses managed instances where you don't access the file system directly.
binlog_cache_size	Yes	
binlog_max_flush_queue_time	Yes	
binlog_order_commits	Yes	
binlog_stmt_cache_size	Yes	
binlog_transaction_compression	Yes	This parameter applies to Aurora MySQL version 3 and higher.
binlog_transaction_compression_level	Yes_zstd	This parameter applies to Aurora MySQL version 3 and higher.
bulk_insert_buffer_size	Yes	
concurrent_insert	Yes	
connect_timeout	Yes	
core-file	No	Aurora MySQL uses managed instances where you don't access the file system directly.
datadir	No	Aurora MySQL uses managed instances where you don't access the file system directly.
default_authentication_plugin	No	This parameter applies to Aurora MySQL version 3 and higher.
default_time_zone	No	
default_tmp_storage_engine	Yes	
default_week_format	Yes	

Parameter name	Modifiable	Notes
delay_key_write	Yes	
delayed_insert_limit	Yes	
delayed_insert_timeout	Yes	
delayed_queue_size	Yes	
div_precision_increment	Yes	
end_markers_in_json	Yes	
eq_range_index_dive_limit	Yes	
event_scheduler	Sometimes	Indicates the status of the Event Scheduler.  Modifiable only at the cluster level in Aurora MySQL version 3.
explicit_defaults_for_timestamp	Yes	
flush	No	
flush_time	Yes	
ft_boolean_syntax	No	
ft_max_word_len	Yes	
ft_min_word_len	Yes	
ft_query_expansion_limit	Yes	
ft_stopword_file	Yes	
general_log	Yes	For instructions on uploading the logs to CloudWatch Logs, see <a href="#">Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs (p. 924)</a> .
general_log_file	No	Aurora MySQL uses managed instances where you don't access the file system directly.
group_concat_max_len	Yes	
host_cache_size	Yes	
init_connect	Yes	
innodb_adaptive_hash_index	Yes	
innodb_adaptive_max_sleep_delay	Yes	Modifying this parameter has no effect, because innodb_thread_concurrency is always 0 for Aurora.
innodb_autoextend_increment	Yes	
innodb_buffer_pool_dump_at_shutdown	No	

Parameter name	Modifiable	Notes
innodb_buffer_pool_dump_now	No	
innodb_buffer_pool_filename	No	
innodb_buffer_pool_load_abort	No	
innodb_buffer_pool_load_at_startup	No	
innodb_buffer_pool_load_now	No	
innodb_buffer_pool_size	Yes	The default value is represented by a formula. For details about how the DBInstanceClassMemory value in the formula is calculated, see <a href="#">DB parameter formula variables (p. 239)</a> .
innodb_change_buffer_max_size	No	Aurora MySQL doesn't use the InnoDB change buffer at all.
innodb_compression_failure_threshold_pct	Yes	
innodb_compression_level	Yes	
innodb_compression_pad_pct_max	Yes	
innodb_concurrency_tickets	Yes	Modifying this parameter has no effect, because innodb_thread_concurrency is always 0 for Aurora.
innodb_deadlock_detect	Yes	This option is used to disable deadlock detection on Aurora MySQL version 3.  On high-concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. Consult the MySQL documentation for more information on this parameter.
innodb_file_format	Yes	Removed from Aurora MySQL version 3.
innodb_flush_log_at_timeout	No	
innodb_flushing_avg_loops	No	
innodb_force_load_corrupted	No	
innodb_ft_aux_table	Yes	
innodb_ft_cache_size	Yes	
innodb_ft_enable_stopword	Yes	
innodb_ft_server_stopword_table	Yes	
innodb_ft_user_stopword_table	Yes	
innodb_large_prefix	Yes	Removed from Aurora MySQL version 3.
innodb_lock_wait_timeout	Yes	

Parameter name	Modifiable	Notes
innodb_log_compressed_pages	No	
innodb_lru_scan_depth	Yes	
innodb_max_purge_lag	Yes	
innodb_max_purge_lag_delay	Yes	
innodb_monitor_disable	Yes	
innodb_monitor_enable	Yes	
innodb_monitor_reset	Yes	
innodb_monitor_reset_all	Yes	
innodb_old_blocks_pct	Yes	
innodb_old_blocks_time	Yes	
innodb_open_files	Yes	
innodb_print_all_deadlocks	Yes	
innodb_random_read_ahead	Yes	
innodb_read_ahead_threshold	Yes	
innodb_read_io_threads	No	
innodb_read_only	No	Aurora MySQL manages the read-only and read/write state of DB instances based on the type of cluster. For example, a provisioned cluster has one read/write DB instance (the <i>primary instance</i> ) and any other instances in the cluster are read-only (the Aurora Replicas).
innodb_replication_delay	Yes	
innodb_sort_buffer_size	Yes	
innodb_stats_auto_recalc	Yes	
innodb_stats_method	Yes	
innodb_stats_on_metadata	Yes	
innodb_stats_persistent	Yes	
innodb_stats_persistent_sample_pages	Yes	
innodb_stats_transient_sample_pages	Yes	
innodb_thread_concurrency	No	
innodb_thread_sleep_delay	Yes	Modifying this parameter has no effect, because innodb_thread_concurrency is always 0 for Aurora.

Parameter name	Modifiable	Notes
interactive_timeout	Yes	Aurora evaluates the minimum value of <code>interactive_timeout</code> and <code>wait_timeout</code> . It then uses that minimum as the timeout to end all idle sessions, both interactive and noninteractive.
internal_tmp_mem_storage_engine	Yes	This parameter applies to Aurora MySQL version 3 and higher.
join_buffer_size	Yes	
keep_files_on_create	Yes	
key_cache_age_threshold	Yes	
key_cache_block_size	Yes	
key_cache_division_limit	Yes	
local_infile	Yes	
lock_wait_timeout	Yes	
log-bin	No	Setting <code>binlog_format</code> to STATEMENT, MIXED, or ROW automatically sets <code>log-bin</code> to ON. Setting <code>binlog_format</code> to OFF automatically sets <code>log-bin</code> to OFF. For more information, see <a href="#">Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 841)</a> .
log_bin_trust_function_creators	Yes	
log_bin_use_v1_row_events	Yes	Removed from Aurora MySQL version 3.
log_error	No	
log_output	Yes	
log_queries_not_using_indexes	Yes	
log_slave_updates	No	Aurora MySQL version 1 and 2. Use <code>log_replica_updates</code> in Aurora MySQL version 3.
log_replica_updates	No	Aurora MySQL version 3 and higher
log_throttle_queries_not_using_indexes	Yes	
log_warnings	Yes	Removed from Aurora MySQL version 3.
long_query_time	Yes	
low_priority_updates	Yes	
max_allowed_packet	Yes	

Parameter name	Modifiable	Notes
max_binlog_cache_size	Yes	
max_binlog_size	No	
max_binlog_stmt_cache_size	Yes	
max_connect_errors	Yes	
max_connections	Yes	The default value is represented by a formula. For details about how the DBInstanceClassMemory value in the formula is calculated, see <a href="#">DB parameter formula variables (p. 239)</a> . For the default values depending on the instance class, see <a href="#">Maximum connections to an Aurora MySQL DB instance (p. 722)</a> .
max_delayed_threads	Yes	
max_error_count	Yes	
max_heap_table_size	Yes	
max_insert_delayed_threads	Yes	
max_join_size	Yes	
max_length_for_sort_data	Yes	Removed from Aurora MySQL version 3.
max_prepared_stmt_count	Yes	
max_seeks_for_key	Yes	
max_sort_length	Yes	
max_sp_recursion_depth	Yes	
max_tmp_tables	Yes	Removed from Aurora MySQL version 3.
max_user_connections	Yes	
max_write_lock_count	Yes	
metadata_locks_cache_size	Yes	Removed from Aurora MySQL version 3.
min_examined_row_limit	Yes	
myisam_data_pointer_size	Yes	
myisam_max_sort_file_size	Yes	
myisam mmap_size	Yes	
myisam_sort_buffer_size	Yes	
myisam_stats_method	Yes	
myisam_use mmap	Yes	
net_buffer_length	Yes	

Parameter name	Modifiable	Notes
net_read_timeout	Yes	
net_retry_count	Yes	
net_write_timeout	Yes	
old-style-user-limits	Yes	
old_passwords	Yes	Removed from Aurora MySQL version 3.
optimizer_prune_level	Yes	
optimizer_search_depth	Yes	
optimizer_switch	Yes	For information about Aurora MySQL features that use this switch, see <a href="#">Best practices with Amazon Aurora MySQL (p. 940)</a> .
optimizer_trace	Yes	
optimizer_trace_features	Yes	
optimizer_trace_limit	Yes	
optimizer_trace_max_mem_size	Yes	
optimizer_trace_offset	Yes	
performance-schema-consumer-events-waits-current	Yes	
performance-schema-instrument	Yes	
performance_schema	Yes	
performance_schema_accounts_size	Yes	
performance_schema_consumer_global_instrumentation	Yes	
performance_schema_consumer_thread_instrumentation	Yes	
performance_schema_consumer_events_stages_current	Yes	
performance_schema_consumer_events_stages_history	Yes	
performance_schema_consumer_events_stages_history_long	Yes	
performance_schema_consumer_events_statements_current	Yes	
performance_schema_consumer_events_statements_history	Yes	
performance_schema_consumer_events_statements_history_long	Yes	
performance_schema_consumer_events_waits_history	Yes	
performance_schema_consumer_events_waits_history_long	Yes	
performance_schema_consumer_statements_digest	Yes	
performance_schema_digests_size	Yes	

Parameter name	Modifiable	Notes
performance_schema_events_stages_history_long_size	Yes	
performance_schema_events_stages_history_size	Yes	
performance_schema_events_statements_history_long_size	Yes	
performance_schema_events_statements_history_size	Yes	
performance_schema_events_transactions_history	Yes	Aurora MySQL 2.x only
performance_schema_events_transactions_history	Yes	Aurora MySQL 2.x only
performance_schema_events_waits_history_long_size	Yes	
performance_schema_events_waits_history_size	Yes	
performance_schema_hosts_size	Yes	
performance_schema_max_cond_classes	Yes	
performance_schema_max_cond_instances	Yes	
performance_schema_max_digest_length	Yes	
performance_schema_max_file_classes	Yes	
performance_schema_max_file_handles	Yes	
performance_schema_max_file_instances	Yes	
performance_schema_max_index_stat	Yes	Aurora MySQL 2.x only
performance_schema_max_memory_classes	Yes	Aurora MySQL 2.x only
performance_schema_max_metadata_locks	Yes	Aurora MySQL 2.x only
performance_schema_max_mutex_classes	Yes	
performance_schema_max_mutex_instances	Yes	
performance_schema_max_prepared_statements_instances	Yes	Aurora MySQL 2.x only
performance_schema_max_program_instances	Yes	Aurora MySQL 2.x only
performance_schema_max_rwlock_classes	Yes	
performance_schema_max_rwlock_instances	Yes	
performance_schema_max_socket_classes	Yes	
performance_schema_max_socket_instances	Yes	
performance_schema_max_sql_text_length	Yes	Aurora MySQL 2.x only
performance_schema_max_stage_classes	Yes	
performance_schema_max_statement_classes	Yes	
performance_schema_max_statement_instances	Yes	Aurora MySQL 2.x only
performance_schema_max_table_handles	Yes	

Parameter name	Modifiable	Notes
performance_schema_max_table_instances	Yes	
performance_schema_max_table_lock_time	Yes	Aurora MySQL 2.x only
performance_schema_max_thread_classes	Yes	
performance_schema_max_thread_instances	Yes	
performance_schema_session_connect_attrs_size	Yes	
performance_schema_setup_actors_size	Yes	
performance_schema_setup_objects_size	Yes	
performance_schema_users_size	Yes	
pid_file	No	
plugin_dir	No	Aurora MySQL uses managed instances where you don't access the file system directly.
port	No	Aurora MySQL manages the connection properties and enforces consistent settings for all DB instances in a cluster.
preload_buffer_size	Yes	
profiling_history_size	Yes	
query_alloc_block_size	Yes	
query_cache_limit	Yes	Removed from Aurora MySQL version 3.
query_cache_min_res_unit	Yes	Removed from Aurora MySQL version 3.
query_cache_size	Yes	The default value is represented by a formula. For details about how the DBInstanceClassMemory value in the formula is calculated, see <a href="#">DB parameter formula variables (p. 239)</a> .  Removed from Aurora MySQL version 3.
query_cache_type	Yes	Removed from Aurora MySQL version 3.
query_cache_wlock_invalidate	Yes	Removed from Aurora MySQL version 3.
query_prealloc_size	Yes	
range_alloc_block_size	Yes	
read_buffer_size	Yes	

Parameter name	Modifiable	Notes
<code>read_only</code>	Yes	Aurora MySQL manages the read-only and read/write state of DB instances based on the type of cluster. For example, a provisioned cluster has one read/write DB instance (the <i>primary instance</i> ) and any other instances in the cluster are read-only (the Aurora Replicas). The writer instance can be switched to a read-only state by changing this parameter. Any reader instances are always in a read-only state, regardless of the value of this parameter.
<code>read_rnd_buffer_size</code>	Yes	
<code>relay-log</code>	No	
<code>relay_log_info_repository</code>	Yes	Removed from Aurora MySQL version 3.
<code>relay_log_recovery</code>	No	
<code>safe-user-create</code>	Yes	
<code>secure_auth</code>	Yes	Removed from Aurora MySQL version 3.
<code>secure_file_priv</code>	No	Aurora MySQL uses managed instances where you don't access the file system directly.
<code>skip-slave-start</code>	No	
<code>skip_external_locking</code>	No	
<code>skip_show_database</code>	Yes	
<code>slave_checkpoint_group</code>	Yes	Aurora MySQL version 1 and 2. Use <code>replica_checkpoint_group</code> in Aurora MySQL version 3.
<code>replica_checkpoint_group</code>	Yes	Aurora MySQL version 3 and higher
<code>slave_checkpoint_period</code>	Yes	Aurora MySQL version 1 and 2. Use <code>replica_checkpoint_period</code> in Aurora MySQL version 3.
<code>replica_checkpoint_period</code>	Yes	Aurora MySQL version 3 and higher
<code>slave_parallel_workers</code>	Yes	Aurora MySQL version 1 and 2. Use <code>replica_parallel_workers</code> in Aurora MySQL version 3.
<code>replica_parallel_workers</code>	Yes	Aurora MySQL version 3 and higher
<code>slave_pending_jobs_size_max</code>	Yes	Aurora MySQL version 1 and 2. Use <code>replica_pending_jobs_size_max</code> in Aurora MySQL version 3.
<code>replica_pending_jobs_size_max</code>	Yes	Aurora MySQL version 3 and higher
<code>replica_skip_errors</code>	Yes	Aurora MySQL version 3 and higher

Parameter name	Modifiable	Notes
slave_sql_verify_checksum	Yes	Aurora MySQL version 1 and 2. Use <code>replica_sql_verify_checksum</code> in Aurora MySQL version 3.
replica_sql_verify_checksum	Yes	Aurora MySQL version 3 and higher
slow_launch_time	Yes	
slow_query_log	Yes	For instructions on uploading the logs to CloudWatch Logs, see <a href="#">Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs (p. 924)</a> .
slow_query_log_file	No	Aurora MySQL uses managed instances where you don't access the file system directly.
socket	No	
sort_buffer_size	Yes	
sql_mode	Yes	
sql_select_limit	Yes	
stored_program_cache	Yes	
sync_binlog	No	
sync_master_info	Yes	
sync_source_info	Yes	This parameter applies to Aurora MySQL 3 and higher.
sync_relay_log	Yes	Removed from Aurora MySQL version 3.
sync_relay_log_info	Yes	
sysdate-is-now	Yes	
table_cache_element_ttl	No	
table_definition_cache	Yes	The default value is represented by a formula. For details about how the <code>DBInstanceClassMemory</code> value in the formula is calculated, see <a href="#">DB parameter formula variables (p. 239)</a> .
table_open_cache	Yes	The default value is represented by a formula. For details about how the <code>DBInstanceClassMemory</code> value in the formula is calculated, see <a href="#">DB parameter formula variables (p. 239)</a> .
table_open_cache_instances	Yes	
temp_pool	Yes	Removed from Aurora MySQL version 3.

Parameter name	Modifiable	Notes
temptable_max_mmap	Yes	This parameter applies to Aurora MySQL version 3 and higher. For details, see <a href="#">New temporary table behavior in Aurora MySQL version 3 (p. 655)</a> .
temptable_max_ram	Yes	This parameter applies to Aurora MySQL version 3 and higher. For details, see <a href="#">New temporary table behavior in Aurora MySQL version 3 (p. 655)</a> .
temptable_use_mmap	Yes	This parameter applies to Aurora MySQL version 3 and higher. For details, see <a href="#">New temporary table behavior in Aurora MySQL version 3 (p. 655)</a> .
thread_handling	No	
thread_stack	Yes	
timed_mutexes	Yes	
tmp_table_size	Yes	
tmpdir	No	Aurora MySQL uses managed instances where you don't access the file system directly.
transaction_alloc_block_size	Yes	
transaction_isolation	Yes	This parameter applies to Aurora MySQL version 3 and higher. It replaces <code>tx_isolation</code> .
transaction_prealloc_size	Yes	
tx_isolation	Yes	Removed from Aurora MySQL version 3. It is replaced by <code>transaction_isolation</code> .
updatable_views_with_limit	Yes	
validate_password	No	
validate_password_dictionary_file	No	
validate_password_length	No	
validate_password_mixed_case_count	No	
validate_password_number_count	No	
validate_password_policy	No	
validate_password_special_char_count	No	

Parameter name	Modifiable	Notes
wait_timeout	Yes	Aurora evaluates the minimum value of <code>interactive_timeout</code> and <code>wait_timeout</code> . It then uses that minimum as the timeout to end all idle sessions, both interactive and noninteractive.

## MySQL parameters that don't apply to Aurora MySQL

Because of architectural differences between Aurora MySQL and MySQL, some MySQL parameters don't apply to Aurora MySQL.

The following MySQL parameters don't apply to Aurora MySQL. This list is not exhaustive.

- `activate_all_roles_on_login`. This parameter isn't applicable to Aurora MySQL version 1 and 2. It is available in Aurora MySQL version 3.
- `big_tables`
- `bind_address`
- `character_sets_dir`
- `innodb_adaptive_flushing`
- `innodb_adaptive_flushing_lwm`
- `innodb_change_buffering`
- `innodb_checksum_algorithm`
- `innodb_data_file_path`
- `innodb_deadlock_detect`. This parameter doesn't apply to Aurora MySQL version 1 and 2. It is available in Aurora MySQL version 3.
- `innodb_dedicated_server`
- `innodb_doublewrite`
- `innodb_flush_method`
- `innodb_flush_neighbors`
- `innodb_io_capacity`
- `innodb_io_capacity_max`
- `innodb_buffer_pool_chunk_size`
- `innodb_buffer_pool_instances`
- `innodb_log_buffer_size`
- `innodb_default_row_format`
- `innodb_log_file_size`
- `innodb_log_files_in_group`
- `innodb_log_spin_cpu_abs_lwm`
- `innodb_log_spin_cpu_pct_hwm`
- `innodb_max_dirty_pages_pct`
- `innodb numa_interleave`
- `innodb_page_size`
- `innodb_redo_log_encrypt`

- `innodb_undo_log_encrypt`
- `innodb_undo_log_truncate`
- `innodb_use_native_aio`
- `innodb_write_io_threads`
- `key_buffer_size` – Key cache for MyISAM tables. This parameter doesn't apply to Aurora.
- `thread_cache_size`

## MySQL status variables that don't apply to Aurora MySQL

Because of architectural differences between Aurora MySQL and MySQL, some MySQL status variables don't apply to Aurora MySQL.

The following MySQL status variables don't apply to Aurora MySQL. This list is not exhaustive.

- `innodb_buffer_pool_bytes_dirty`
- `innodb_buffer_pool_pages_dirty`
- `innodb_buffer_pool_pages_flushed`

Aurora MySQL version 3 removes the following status variables that were in Aurora MySQL version 2:

- `AuroraDb_lockmgr_bitmaps0_in_use`
- `AuroraDb_lockmgr_bitmaps1_in_use`
- `AuroraDb_lockmgr_bitmaps_mem_used`
- `AuroraDb_thread_deadlocks`
- `available_alter_table_log_entries`
- `Aurora_lockmgr_memory_used`
- `Aurora_missing_history_on_replica_incidents`
- `Aurora_new_lock_manager_lock_release_cnt`
- `Aurora_new_lock_manager_lock_release_total_duration_micro`
- `Aurora_new_lock_manager_lock_timeout_cnt`
- `Aurora_oom_response`
- `Aurora_total_op_memory`
- `Aurora_total_op_temp_space`
- `Aurora_used_alter_table_log_entries`
- `Aurora_using_new_lock_manager`
- `Aurora_volume_bytes_allocated`
- `Aurora_volume_bytes_left_extent`
- `Aurora_volume_bytes_left_total`
- `Com.Alter_db_upgrade`
- `Compression`
- `External_threads_connected`
- `Innodb_available_undo_logs`
- `Last_query_cost`
- `Last_query_partial_plans`

- Slave\_heartbeat\_period
- Slave\_last\_heartbeat
- Slave\_received\_heartbeats
- Slave\_retried\_transactions
- Slave\_running
- Time\_since\_zero\_connections

These MySQL status variables are available in Aurora MySQL version 1 or 2, but they aren't available in Aurora MySQL version 3:

- Innodb\_redo\_log\_enabled
- Innodb\_undo tablespaces\_total
- Innodb\_undo tablespaces\_implicit
- Innodb\_undo tablespaces\_explicit
- Innodb\_undo tablespaces\_active

## Aurora MySQL wait events

The following are some common wait events for Aurora MySQL.

### Note

For information about the naming conventions used in MySQL wait events, see [Performance Schema instrument naming conventions](#) in the MySQL documentation.

#### cpu

The number of active connections that are ready to run is consistently higher than the number of vCPUs. For more information, see [cpu \(p. 750\)](#).

#### io/aurora\_redo\_log\_flush

A session is persisting data to Aurora storage. Typically, this wait event is for a write I/O operation in Aurora MySQL. For more information, see [io/aurora\\_redo\\_log\\_flush \(p. 753\)](#).

#### io/aurora\_respond\_to\_client

Query processing has completed and results are being returned to the application client for the following Aurora MySQL versions: 2.10.2 and higher 2.10 versions, 2.09.3 and higher 2.09 versions, 2.07.7 and higher 2.07 versions, and 1.22.6 and higher 1.22 versions. Compare the network bandwidth of the DB instance class with the size of the result set being returned. Also, check client-side response times. If the client is unresponsive and can't process the TCP packets, packet drops and TCP retransmissions can occur. This situation negatively affects network bandwidth. In versions lower than 2.10.2, 2.09.3, 2.07.7, and 1.22.6, the wait event erroneously includes idle time. To learn how to tune your database when this wait is prominent, see [io/aurora\\_respond\\_to\\_client \(p. 756\)](#).

#### io/file/csv/data

Threads are writing to tables in comma-separated value (CSV) format. Check your CSV table usage. A typical cause of this event is setting log\_output on a table.

#### io/file/innodb/innodb\_data\_file

Threads are waiting on I/O from storage. This event is more prevalent in I/O-intensive workloads. When this wait event is prevalent, SQL statements might be running disk-intensive queries or requesting data that can't be satisfied from the InnoDB buffer pool. For more information, see [io/file/innodb/innodb\\_data\\_file \(p. 758\)](#).

### **io/file/sql/binlog**

A thread is waiting on a binary log (binlog) file that is being written to disk.

### **io/socket/sql/client\_connection**

The `mysqld` program is busy creating threads to handle incoming new client connections. For more information, see [io/socket/sql/client\\_connection \(p. 760\)](#).

### **io/table/sql/handler**

The engine is waiting for access to a table. This event occurs regardless of whether the data is cached in the buffer pool or accessed on disk. For more information, see [io/table/sql/handler \(p. 762\)](#).

### **lock/table/sql/handler**

This wait event is a table lock wait event handler. For more information about atom and molecule events in the Performance Schema, see [Performance Schema atom and molecule events](#) in the MySQL documentation.

### **synch/cond/mysys/my\_thread\_var::suspend**

The thread is suspended while waiting on a table-level lock because another thread issued `LOCK TABLES ... READ`.

### **synch/cond/sql/MDL\_context::COND\_wait\_status**

Threads are waiting on a table metadata lock. The engine uses this type of lock to manage concurrent access to a database schema and to ensure data consistency. For more information, see [Optimizing locking operations](#) in the MySQL documentation. To learn how to tune your database when this event is prominent, see [synch/cond/sql/MDL\\_context::COND\\_wait\\_status \(p. 766\)](#).

### **synch/cond/sql/MYSQL\_BIN\_LOG::COND\_done**

You have turned on binary logging. There might be a high commit throughput, large number transactions committing, or replicas reading binlogs. Consider using multirow statements or bundling statements into one transaction. In Aurora, use global databases instead of binary log replication, or use the `aurora_binlog_*` parameters.

### **synch/mutex/innodb/aurora\_lock\_thread\_slot\_futex**

Multiple data manipulation language (DML) statements are accessing the same database rows at the same time. For more information, see [synch/mutex/innodb/aurora\\_lock\\_thread\\_slot\\_futex \(p. 773\)](#).

### **synch/mutex/innodb/buf\_pool\_mutex**

The buffer pool isn't large enough to hold the working data set. Or the workload accesses pages from a specific table, which leads to contention in the buffer pool. For more information, see [synch/mutex/innodb/buf\\_pool\\_mutex \(p. 775\)](#).

### **synch/mutex/innodb/fil\_system\_mutex**

The process is waiting for access to the tablespace memory cache. For more information, see [synch/mutex/innodb/fil\\_system\\_mutex \(p. 777\)](#).

### **synch/mutex/innodb/os\_mutex**

This event is part of an event semaphore. It provides exclusive access to variables used for signaling between threads. Uses include statistics threads, full-text search, buffer pool dump and load operations, and log flushes. This wait event is specific to Aurora MySQL version 1.

### **synch/mutex/innodb/trx\_sys\_mutex**

Operations are checking, updating, deleting, or adding transaction IDs in InnoDB in a consistent or controlled manner. These operations require a `trx_sys` mutex call, which is tracked by Performance

Schema instrumentation. Operations include management of the transaction system when the database starts or shuts down, rollbacks, undo cleanups, row read access, and buffer pool loads. High database load with a large number of transactions results in the frequent appearance of this wait event. For more information, see [synch/mutex/innodb/trx\\_sys\\_mutex \(p. 780\)](#).

#### **synch/mutex/mysys/KEY\_CACHE::cache\_lock**

The keycache->cache\_lock mutex controls access to the key cache for MyISAM tables. This wait event doesn't apply to Aurora MySQL, because the MyISAM storage engine isn't supported for persistent tables.

#### **synch/mutex/sql/FILE\_AS\_TABLE::LOCK\_offsets**

The engine acquires this mutex when opening or creating a table metadata file. When this wait event occurs with excessive frequency, the number of tables being created or opened has spiked.

#### **synch/mutex/sql/FILE\_AS\_TABLE::LOCK\_shim\_lists**

The engine acquires this mutex while performing operations such as `reset_size`, `detach_contents`, or `add_contents` on the internal structure that keeps track of opened tables. The mutex synchronizes access to the list contents. When this wait event occurs with high frequency, it indicates a sudden change in the set of tables that were previously accessed. The engine needs to access new tables or let go of the context related to previously accessed tables.

#### **synch/mutex/sql/LOCK\_open**

The number of tables that your sessions are opening exceeds the size of the table definition cache or the table open cache. Increase the size of these caches. For more information, see [How MySQL opens and closes tables](#).

#### **synch/mutex/sql/LOCK\_table\_cache**

The number of tables that your sessions are opening exceeds the size of the table definition cache or the table open cache. Increase the size of these caches. For more information, see [How MySQL opens and closes tables](#).

#### **synch/mutex/sql/LOG**

In this wait event, there are threads waiting on a log lock. For example, a thread might wait for a lock to write to the slow query log file.

#### **synch/mutex/sql/MYSQL\_BIN\_LOG::LOCK\_commit**

In this wait event, there is a thread that is waiting to acquire a lock with the intention of committing to the binary log. Binary logging contention can occur on databases with a very high change rate. Depending on your version of MySQL, there are certain locks being used to protect the consistency and durability of the binary log. In RDS for MySQL, binary logs are used for replication and the automated backup process. In Aurora MySQL, binary logs are not needed for native replication or backups. They are disabled by default but can be enabled and used for external replication or change data capture. For more information, see [The binary log](#) in the MySQL documentation.

#### **sync/mutex/sql/MYSQL\_BIN\_LOG::LOCK\_dump\_thread\_metrics\_collection**

If binary logging is turned on, the engine acquires this mutex when it prints active dump threads metrics to the engine error log and to the internal operations map.

#### **sync/mutex/sql/MYSQL\_BIN\_LOG::LOCK\_inactive\_binlogs\_map**

If binary logging is turned on, the engine acquires this mutex when it adds to, deletes from, or searches through the list of binlog files behind the latest one.

#### **sync/mutex/sql/MYSQL\_BIN\_LOG::LOCK\_io\_cache**

If binary logging is turned on, the engine acquires this mutex during Aurora binlog IO cache operations: allocate, resize, free, write, read, purge, and access cache info. If this event occurs

frequently, the engine is accessing the cache where binlog events are stored. To reduce wait times, reduce commits. Try grouping multiple statements into a single transaction.

#### **synch/mutex/sql/MYSQL\_BIN\_LOG::LOCK\_log**

You have turned on binary logging. There might be high commit throughput, many transactions committing, or replicas reading binlogs. Consider using multirow statements or bundling statements into one transaction. In Aurora, use global databases instead of binary log replication or use the `aurora_binlog_*` parameters.

#### **synch/mutex/sql/SERVER\_THREAD::LOCK\_sync**

The mutex `SERVER_THREAD::LOCK_sync` is acquired during the scheduling, processing, or launching of threads for file writes. The excessive occurrence of this wait event indicates increased write activity in the database.

#### **synch/rwlock/innodb/dict**

The engine acquires the `TABLESPACES:lock` mutex during the following tablespace operations: create, delete, truncate, and extend. The excessive occurrence of this wait event indicates a high frequency of tablespace operations. An example is loading a large amount of data into the database.

#### **synch/rwlock/innodb/dict\_operation\_lock**

In this wait event, there are threads waiting on an rwlock held on the InnoDB data dictionary.

#### **synch/rwlock/innodb/dict sys RW lock**

A high number of concurrent data control language statements (DCLs) in data definition language code (DDFs) are triggered at the same time. Reduce the application's dependency on DDFs during regular application activity.

#### **synch/rwlock/innodb/hash\_table\_locks**

The excessive occurrence of this wait event indicates contention when modifying the hash table that maps the buffer cache. Consider increasing the buffer cache size and improving access paths for the relevant queries. To learn how to tune your database when this wait is prominent, see [synch/rwlock/innodb/hash\\_table\\_locks \(p. 781\)](#).

#### **synch/rwlock/innodb/index\_tree\_rw\_lock**

A large number of similar data manipulation language (DML) statements are accessing the same database object at the same time. Try using multirow statements. Also, spread the workload over different database objects. For example, implement partitioning.

#### **synch/sxlock/innodb/dict\_operation\_lock**

A high number of concurrent data control language statements (DCLs) in data definition language code (DDFs) are triggered at the same time. Reduce the application's dependency on DDFs during regular application activity.

#### **synch/sxlock/innodb/dict\_sys\_lock**

A high number of concurrent data control language statements (DCLs) in data definition language code (DDFs) are triggered at the same time. Reduce the application's dependency on DDFs during regular application activity.

#### **synch/sxlock/innodb/hash\_table\_locks**

The session couldn't find pages in the buffer pool. The engine either needs to read a file or modify the least-recently used (LRU) list for the buffer pool. Consider increasing the buffer cache size and improving access paths for the relevant queries.

### **synch/sxlock/innodb/index\_tree\_rw\_lock**

Many similar data manipulation language (DML) statements are accessing the same database object at the same time. Try using multirow statements. Also, spread the workload over different database objects. For example, implement partitioning.

For more information on troubleshooting synch wait events, see [Why is my MySQL DB instance showing a high number of active sessions waiting on SYNCH wait events in Performance Insights?](#).

## Aurora MySQL thread states

The following are some common thread states for Aurora MySQL.

### **checking permissions**

The thread is checking whether the server has the required privileges to run the statement.

### **checking query cache for query**

The server is checking whether the current query is present in the query cache.

### **cleaned up**

This is the final state of a connection whose work is complete but which hasn't been closed by the client. The best solution is to explicitly close the connection in code. Or you can set a lower value for `wait_timeout` in your parameter group.

### **closing tables**

The thread is flushing the changed table data to disk and closing the used tables. If this isn't a fast operation, verify the network bandwidth consumption metrics against the instance class network bandwidth. Also, check that the parameter values for `table_open_cache` and `table_definition_cache` parameter allow for enough tables to be simultaneously open so that the engine doesn't need to open and close tables frequently. These parameters influence the memory consumption on the instance.

### **converting HEAP to MyISAM**

The query is converting a temporary table from in-memory to on-disk. This conversion is necessary because the temporary tables created by MySQL in the intermediate steps of query processing grew too big for memory. Check the values of `tmp_table_size` and `max_heap_table_size`. In later versions, this thread state name is `converting HEAP to ondisk`.

### **converting HEAP to ondisk**

The thread is converting an internal temporary table from an in-memory table to an on-disk table.

### **copy to tmp table**

The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it. For a thread in this state, you can use the Performance Schema to obtain information about the progress of the copy operation.

### **creating sort index**

Aurora MySQL is performing a sort because it can't use an existing index to satisfy the `ORDER BY` or `GROUP BY` clause of a query. For more information, see [creating sort index \(p. 785\)](#).

### **creating table**

The thread is creating a permanent or temporary table.

### **delayed commit ok done**

An asynchronous commit in Aurora MySQL has received an acknowledgement and is complete.

### **delayed commit ok initiated**

The Aurora MySQL thread has started the async commit process but is waiting for acknowledgement. This is usually the genuine commit time of a transaction.

### **delayed send ok done**

An Aurora MySQL worker thread that is tied to a connection can be freed while a response is sent to the client. The thread can begin other work. The state `delayed_send_ok` means that the asynchronous acknowledgement to the client completed.

### **delayed send ok initiated**

An Aurora MySQL worker thread has sent a response asynchronously to a client and is now free to do work for other connections. The transaction has started an async commit process that hasn't yet been acknowledged.

### **executing**

The thread has begun running a statement.

### **freeing items**

The thread has run a command. Some freeing of items done during this state involves the query cache. This state is usually followed by cleaning up.

### **init**

This state occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions in this state include flushing the binary log or InnoDB log, and some cleanup of the query cache.

### **master has sent all binlog to slave**

The primary node has finished its part of the replication. The thread is waiting for more queries to run so that it can write to the binary log (binlog).

### **opening tables**

The thread is trying to open a table. This operation is fast unless an `ALTER TABLE` or a `LOCK TABLE` statement needs to finish, or it exceeds the value of `table_open_cache`.

### **optimizing**

The server is performing initial optimizations for a query.

### **preparing**

This state occurs during query optimization.

### **query end**

This state occurs after processing a query but before the freeing items state.

### **removing duplicates**

Aurora MySQL couldn't optimize a `DISTINCT` operation in the early stage of a query. Aurora MySQL must remove all duplicated rows before sending the result to the client.

### **searching rows for update**

The thread is finding all matching rows before updating them. This stage is necessary if the `UPDATE` is changing the index that the engine uses to find the rows.

### **sending binlog event to slave**

The thread read an event from the binary log and is sending it to the replica.

### **sending cached result to client**

The server is taking the result of a query from the query cache and sending it to the client.

### **sending data**

The thread is reading and processing rows for a `SELECT` statement but hasn't yet started sending data to the client. The process is identifying which pages contain the results necessary to satisfy the query. For more information, see [sending data \(p. 788\)](#).

### **sending to client**

The server is writing a packet to the client. In earlier MySQL versions, this wait event was labeled `writing to net`.

### **starting**

This is the first stage at the beginning of statement execution.

### **statistics**

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound while performing other work.

### **storing result in query cache**

The server is storing the result of a query in the query cache.

### **system lock**

The thread has called `mysql_lock_tables`, but the thread state hasn't been updated since the call. This general state occurs for many reasons.

### **update**

The thread is preparing to start updating the table.

### **updating**

The thread is searching for rows and is updating them.

### **user lock**

The thread issued a `GET_LOCK` call. The thread either requested an advisory lock and is waiting for it, or is planning to request it.

### **waiting for more updates**

The primary node has finished its part of the replication. The thread is waiting for more queries to run so that it can write to the binary log (binlog).

### **waiting for schema metadata lock**

This is a wait for a metadata lock.

### **waiting for stored function metadata lock**

This is a wait for a metadata lock.

### **waiting for stored procedure metadata lock**

This is a wait for a metadata lock.

### **waiting for table flush**

The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables. Or the thread received notification that the underlying structure for a table changed, so it must reopen the table to get the new structure. To reopen the table, the thread must wait until all other threads have closed the table. This notification takes place if another thread has used one of the following

statements on the table: FLUSH TABLES, ALTER TABLE, RENAME TABLE, REPAIR TABLE, ANALYZE TABLE, or OPTIMIZE TABLE.

#### **waiting for table level lock**

One session is holding a lock on a table while another session tries to acquire the same lock on the same table.

#### **waiting for table metadata lock**

Aurora MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. In this wait event, one session is holding a metadata lock on a table while another session tries to acquire the same lock on the same table. When the Performance Schema is enabled, this thread state is reported as the wait event synch/cond/sql/MDL\_context::COND\_wait\_status.

#### **writing to net**

The server is writing a packet to the network. In later MySQL versions, this wait event is labeled Sending to client.

## Aurora MySQL isolation levels

Following, you can learn how DB instances in an Aurora MySQL cluster implement the database property of isolation. Doing so helps you understand how the Aurora MySQL default behavior balances between strict consistency and high performance. You can also decide when to change the default settings based on the characteristics of your workload.

### Available isolation levels for writer instances

You can use the isolation levels REPEATABLE READ, READ COMMITTED, READ UNCOMMITTED, and SERIALIZABLE on the primary instance of an Aurora MySQL single-master cluster. You can use the isolation levels REPEATABLE READ, READ COMMITTED, and READ UNCOMMITTED on any DB instance in an Aurora MySQL multi-master cluster. These isolation levels work the same in Aurora MySQL as in RDS for MySQL.

### REPEATABLE READ isolation level for reader instances

By default, Aurora MySQL DB instances configured as read-only Aurora Replicas always use the REPEATABLE READ isolation level. These DB instances ignore any SET TRANSACTION ISOLATION LEVEL statements and continue using the REPEATABLE READ isolation level.

### READ COMMITTED isolation level for reader instances

If your application includes a write-intensive workload on the primary instance and long-running queries on the Aurora Replicas, you might experience substantial purge lag. *Purge lag* happens when internal garbage collection is blocked by long-running queries. The symptom that you see is a high value for history list length in output from the SHOW ENGINE INNODB STATUS command. You can monitor this value using the RollbackSegmentHistoryListLength metric in CloudWatch. This condition can reduce the effectiveness of secondary indexes and lead to reduced overall query performance and wasted storage space.

If you experience such issues, you can use an Aurora MySQL session-level configuration setting, aurora\_read\_replica\_read\_committed, to use the READ COMMITTED isolation level on Aurora Replicas. Using this setting can help reduce slowdowns and wasted space that can result from performing long-running queries at the same time as transactions that modify your tables.

We recommend making sure that you understand the specific Aurora MySQL behavior of the READ COMMITTED isolation before using this setting. The Aurora Replica READ COMMITTED behavior

complies with the ANSI SQL standard. However, the isolation is less strict than typical MySQL `READ COMMITTED` behavior that you might be familiar with. Thus, you might see different query results under `READ COMMITTED` on an Aurora MySQL read replica than for the same query under `READ COMMITTED` on the Aurora MySQL primary instance or on RDS for MySQL. You might use the `aurora_read_replica_read_committed` setting for such use cases as a comprehensive report that scans a very large database. You might avoid it for short queries with small result sets, where precision and repeatability are important.

The `READ COMMITTED` isolation level isn't available for sessions within a secondary cluster in an Aurora global database that use the write forwarding feature. For information about write forwarding, see [Using write forwarding in an Amazon Aurora global database \(p. 181\)](#).

## Enabling `READ COMMITTED` for readers

To enable the `READ COMMITTED` isolation level for Aurora Replicas, enable the `aurora_read_replica_read_committed` configuration setting. Enable this setting at the session level while connected to a specific Aurora Replica. To do so, run the following SQL commands.

```
set session aurora_read_replica_read_committed = ON;
set session transaction isolation level read committed;
```

You might enable this configuration setting temporarily to perform interactive ad hoc (one-time) queries. You might also want to run a reporting or data analysis application that benefits from the `READ COMMITTED` isolation level, while leaving the default unchanged for other applications.

When the `aurora_read_replica_read_committed` setting is enabled, use the `SET TRANSACTION ISOLATION LEVEL` command to specify the isolation level for the appropriate transactions.

```
set transaction isolation level read committed;
```

## Differences in `READ COMMITTED` behavior on Aurora replicas

The `aurora_read_replica_read_committed` setting makes the `READ COMMITTED` isolation level available for an Aurora Replica, with consistency behavior that is optimized for long-running transactions. The `READ COMMITTED` isolation level on Aurora Replicas has less strict isolation than on Aurora primary instances or multi-master instances. For that reason, enable this setting only on Aurora Replicas where you know that your queries can accept the possibility of certain types of inconsistent results.

Your queries can experience certain kinds of read anomalies when the `aurora_read_replica_read_committed` setting is turned on. Two kinds of anomalies are especially important to understand and handle in your application code. A *non-repeatable read* occurs when another transaction commits while your query is running. A long-running query can see different data at the start of the query than it sees at the end. A *phantom read* occurs when other transactions cause existing rows to be reorganized while your query is running, and one or more rows are read twice by your query.

Your queries might experience inconsistent row counts as a result of phantom reads. Your queries might also return incomplete or inconsistent results due to non-repeatable reads. For example, suppose that a join operation refers to tables that are concurrently modified by SQL statements such as `INSERT` or `DELETE`. In this case, the join query might read a row from one table but not the corresponding row from another table.

The ANSI SQL standard allows both of these behaviors for the `READ COMMITTED` isolation level. However, those behaviors are different than the typical MySQL implementation of `READ COMMITTED`. Thus, before enabling the `aurora_read_replica_read_committed` setting, check any existing SQL code to verify if it operates as expected under the looser consistency model.

Row counts and other results might not be strongly consistent under the `READ COMMITTED` isolation level while this setting is enabled. Thus, you typically enable the setting only while running analytic queries that aggregate large amounts of data and don't require absolute precision. If you don't have these kinds of long-running queries alongside a write-intensive workload, you probably don't need the `aurora_read_replica_read_committed` setting. Without the combination of long-running queries and a write-intensive workload, you're unlikely to encounter issues with the length of the history list.

### Example Queries showing isolation behavior for READ COMMITTED on Aurora replicas

The following example shows how `READ COMMITTED` queries on an Aurora Replica might return non-repeatable results if transactions modify the associated tables at the same time. The table `BIG_TABLE` contains 1 million rows before any queries start. Other data manipulation language (DML) statements add, remove, or change rows while the are running.

The queries on the Aurora primary instance under the `READ COMMITTED` isolation level produce predictable results. However, the overhead of keeping the consistent read view for the lifetime of every long-running query can lead to expensive garbage collection later.

The queries on the Aurora Replica under the `READ COMMITTED` isolation level are optimized to minimize this garbage collection overhead. The tradeoff is that the results might vary depending on whether the queries retrieve rows that are added, removed, or reorganized by transactions that commit while the query is running. The queries are allowed to consider these rows but aren't required to. For demonstration purposes, the queries check only the number of rows in the table by using the `COUNT(*)` function.

Time	DML statement on Aurora primary instance	Query on Aurora primary instance with <code>READ COMMITTED</code>	Query on Aurora replica with <code>READ COMMITTED</code>
T1	<code>INSERT INTO big_table SELECT * FROM other_table LIMIT 1000000; COMMIT;</code>		
T2		<b>Q1:</b> <code>SELECT COUNT(*) FROM big_table;</code>	<b>Q2:</b> <code>SELECT COUNT(*) FROM big_table;</code>
T3	<code>INSERT INTO big_table (c1, c2) VALUES (1, 'one more row'); COMMIT;</code>		
T4		If Q1 finishes now, result is 1,000,000.	If Q2 finishes now, result is 1,000,000 or 1,000,001.
T5	<code>DELETE FROM big_table LIMIT 2; COMMIT;</code>		
T6		If Q1 finishes now, result is 1,000,000.	If Q2 finishes now, result is 1,000,000 or 1,000,001 or 999,999 or 999,998.
T7	<code>UPDATE big_table SET c2 =</code>		

Time	DML statement on Aurora primary instance	Query on Aurora primary instance with READ COMMITTED	Query on Aurora replica with READ COMMITTED
	CONCAT(c2,c2,c2); COMMIT;		
T8		If Q1 finishes now, result is 1,000,000.	If Q2 finishes now, result is 1,000,000 or 1,000,001 or 999,999, or possibly some higher number.
T9		<b>Q3:</b> SELECT COUNT(*) FROM big_table;	<b>Q4:</b> SELECT COUNT(*) FROM big_table;
T10		If Q3 finishes now, result is 999,999.	If Q4 finishes now, result is 999,999.
T11		<b>Q5:</b> SELECT COUNT(*) FROM parent_table p JOIN child_table c ON (p.id = c.id) WHERE p.id = 1000;	<b>Q6:</b> SELECT COUNT(*) FROM parent_table p JOIN child_table c ON (p.id = c.id) WHERE p.id = 1000;
T12	INSERT INTO parent_table (id, s) VALUES (1000, 'hello'); INSERT INTO child_table (id, s) VALUES (1000, 'world'); COMMIT;		
T13		If Q5 finishes now, result is 0.	If Q6 finishes now, result is 0 or 1.

If the queries finish quickly, before any other transactions perform DML statements and commit, the results are predictable and the same between the primary instance and the Aurora Replica.

The results for Q1 are highly predictable, because `READ COMMITTED` on the primary instance uses a strong consistency model similar to the `REPEATABLE READ` isolation level.

The results for Q2 might vary depending on what transactions commit while that query is running. For example, suppose that other transactions perform DML statements and commit while the queries are running. In this case, the query on the Aurora Replica with the `READ COMMITTED` isolation level might or might not take the changes into account. The row counts are not predictable in the same way as under the `REPEATABLE READ` isolation level. They also aren't as predictable as queries running under the `READ COMMITTED` isolation level on the primary instance, or on an RDS for MySQL instance.

The `UPDATE` statement at T7 doesn't actually change the number of rows in the table. However, by changing the length of a variable-length column, this statement can cause rows to be reorganized internally. A long-running `READ COMMITTED` transaction might see the old version of a row, and later within the same query see the new version of the same row. The query can also skip both the old and new versions of the row. Thus, the row count might be different than expected.

The results of Q5 and Q6 might be identical or slightly different. Query Q6 on the Aurora Replica under `READ COMMITTED` is able to see, but is not required to see, the new rows that are committed while the query is running. It might also see the row from one table but not from the other table. If the join query

doesn't find a matching row in both tables, it returns a count of zero. If the query does find both the new rows in `PARENT_TABLE` and `CHILD_TABLE`, the query returns a count of one. In a long-running query, the lookups from the joined tables might happen at widely separated times.

**Note**

These differences in behavior depend on the timing of when transactions are committed and when the queries process the underlying table rows. Thus, you're most likely to see such differences in report queries that take minutes or hours and that run on Aurora clusters processing OLTP transactions at the same time. These are the kinds of mixed workloads that benefit the most from the `READ COMMITTED` isolation level on Aurora Replicas.

## Aurora MySQL hints

You can use SQL hints with Aurora MySQL queries to fine-tune performance. You can also use hints to prevent execution plans for important queries to change based on unpredictable conditions.

**Tip**

To verify the effect that a hint has on a query, examine the query plan produced by the `EXPLAIN` statement. Compare the query plans with and without the hint.

In Aurora MySQL version 3, you can use all the hints that are available in community MySQL 8.0. For details about these hints, see [Optimizer Hints](#) in the *MySQL Reference Manual*.

The following hints are available in Aurora MySQL 2.08 and higher. These hints apply to queries that use the hash join feature in Aurora MySQL version 2, especially queries that use the parallel query optimization.

### HASH\_JOIN, NO\_HASH\_JOIN

Turns on or off the ability of the optimizer to choose whether to use the hash join optimization method for a query. `HASH_JOIN` enables the optimizer to use hash join if that mechanism is more efficient. `NO_HASH_JOIN` prevents the optimizer from using hash join for the query. This hint is available in Aurora MySQL 2.08 and higher minor versions. It has no effect in Aurora MySQL version 3.

The following examples show how to use this hint.

```
EXPLAIN SELECT /*+ HASH_JOIN(t2) */ f1, f2
    FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ NO_HASH_JOIN(t2) */ f1, f2
    FROM t1, t2 WHERE t1.f1 = t2.f1;
```

### HASH\_JOIN\_PROBING, NO\_HASH\_JOIN\_PROBING

In a hash join query, specifies whether or not to use the specified table for the probe side of the join. The query tests whether column values from the build table exist in the probe table, instead of reading the entire contents of the probe table. You can use `HASH_JOIN_PROBING` and `HASH_JOIN_BUILDING` to specify how hash join queries are processed without reordering the tables within the query text. This hint is available in Aurora MySQL 2.08 and higher minor versions. It has no effect in Aurora MySQL version 3.

The following examples show how to use this hint. Specifying the `HASH_JOIN_PROBING` hint for the table `T2` has the same effect as specifying `NO_HASH_JOIN_PROBING` for the table `T1`.

```
EXPLAIN SELECT /*+ HASH_JOIN(t2) HASH_JOIN_PROBING(t2) */ f1, f2
    FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ HASH_JOIN(t2) NO_HASH_JOIN_PROBING(t1) */ f1, f2
    FROM t1, t2 WHERE t1.f1 = t2.f1;
```

## HASH\_JOIN\_BUILDING, NO\_HASH\_JOIN\_BUILDING

In a hash join query, specifies whether or not to use the specified table for the build side of the join. The query processes all the rows from this table to build the list of column values to cross-reference with the other table. You can use `HASH_JOIN_PROBING` and `HASH_JOIN_BUILDING` to specify how hash join queries are processed without reordering the tables within the query text. This hint is available in Aurora MySQL 2.08 and higher minor versions. It has no effect in Aurora MySQL version 3.

The following examples show how to use this hint. Specifying the `HASH_JOIN_BUILDING` hint for the table `T2` has the same effect as specifying `NO_HASH_JOIN_BUILDING` for the table `T1`.

```
EXPLAIN SELECT /*+ HASH_JOIN(t2) HASH_JOIN_BUILDING(t2) */ f1, f2
    FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ HASH_JOIN(t2) NO_HASH_JOIN_BUILDING(t1) */ f1, f2
    FROM t1, t2 WHERE t1.f1 = t2.f1;
```

## JOIN\_FIXED\_ORDER

Specifies that tables in the query are joined based on the order they are listed in the query. It is especially useful with queries involving three or more tables. It is intended as a replacement for the MySQL `STRAIGHT_JOIN` hint. Equivalent to the MySQL `JOIN_FIXED_ORDER` hint. This hint is available in Aurora MySQL 2.08 and higher.

The following examples show how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_FIXED_ORDER */ f1, f2
    FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

## JOIN\_ORDER

Specifies the join order for the tables in the query. It is especially useful with queries involving three or more tables. Equivalent to the MySQL `JOIN_ORDER` hint. This hint is available in Aurora MySQL 2.08 and higher.

The following examples show how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_ORDER (t4, t2, t1, t3) */ f1, f2
    FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

## JOIN\_PREFIX

Specifies the tables to put first in the join order. It is especially useful with queries involving three or more tables. Equivalent to the MySQL `JOIN_PREFIX` hint. This hint is available in Aurora MySQL 2.08 and higher.

The following examples show how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_ORDER (t4, t2) */ f1, f2
    FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

## JOIN\_SUFFIX

Specifies the tables to put last in the join order. It is especially useful with queries involving three or more tables. Equivalent to the MySQL `JOIN_SUFFIX` hint. This hint is available in Aurora MySQL 2.08 and higher.

The following examples show how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_ORDER (t1, t3) */ f1, f2
    FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

For information about using hash join queries, see [Optimizing large Aurora MySQL join queries with hash joins \(p. 945\)](#).

## Aurora MySQL stored procedures

You can call the following stored procedures while connected to the primary instance in an Aurora MySQL cluster. These procedures control how transactions are replicated from an external database into Aurora MySQL, or from Aurora MySQL to an external database. To learn how to use replication based on global transaction identifiers (GTIDs) with Aurora MySQL, see [Using GTID-based replication for Amazon Aurora MySQL \(p. 863\)](#).

### Topics

- [mysql.rds\\_assign\\_gtids\\_to\\_anonymous\\_transactions \(Aurora MySQL version 3 and higher\) \(p. 984\)](#)
- [mysql.rds\\_set\\_master\\_auto\\_position \(Aurora MySQL version 1 and 2\) \(p. 985\)](#)
- [mysql.rds\\_set\\_source\\_auto\\_position \(Aurora MySQL version 3 and higher\) \(p. 986\)](#)
- [mysql.rds\\_set\\_external\\_master\\_with\\_auto\\_position \(Aurora MySQL version 1 and 2\) \(p. 986\)](#)
- [mysql.rds\\_set\\_external\\_source\\_with\\_auto\\_position \(Aurora MySQL version 3 and higher\) \(p. 988\)](#)
- [mysql.rds\\_skip\\_transaction\\_with\\_gtid \(p. 989\)](#)

## mysql.rds\_assign\_gtids\_to\_anonymous\_transactions (Aurora MySQL version 3 and higher)

### Syntax

```
CALL mysql.rds_assign_gtids_to_anonymous_transactions(gtid_option);
```

### Parameters

#### *gtid\_option*

String value. The allowed values are OFF, LOCAL, or a specified UUID.

### Usage notes

This procedure has the same effect as issuing the statement `CHANGE REPLICATION SOURCE TO ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS = gtid_option` in community MySQL.

GTID must be turned to ON for *gtid\_option* to be set to LOCAL or a specific UUID.

The default is OFF, meaning that the feature is not used.

LOCAL assigns a GTID including the replica's own UUID (the `server_uuid` setting).

Passing a parameter that is a UUID assigns a GTID that includes the specified UUID, such as the `server_uuid` setting for the replication source server.

### Examples

To turn off this feature:

```
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('OFF');
+-----+
| Message |
+-----+
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: OFF |
+-----+
1 row in set (0.07 sec)
```

To use the replica's own UUID:

```
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('LOCAL');
+-----+
| Message |
+-----+
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: LOCAL |
+-----+
1 row in set (0.07 sec)
```

To use a specified UUID:

```
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('317a4760-
f3dd-3b74-8e45-0615ed29de0e');
+-----+
| Message |
+-----+
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: 317a4760-
f3dd-3b74-8e45-0615ed29de0e |
+-----+
1 row in set (0.07 sec)
```

## [mysql.rds\\_set\\_master\\_auto\\_position \(Aurora MySQL version 1 and 2\)](#)

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

### Syntax

```
CALL mysql.rds_set_master_auto_position (auto_position_mode);
```

### Parameters

#### *auto\_position\_mode*

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

### Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The master user must run the `mysql.rds_set_master_auto_position` procedure.

For Aurora, this procedure is supported for Aurora MySQL version 2.04 and later MySQL 5.7-compatible versions. GTID-based replication isn't supported for Aurora MySQL 1.1 or 1.0.

## mysql.rds\_set\_source\_auto\_position (Aurora MySQL version 3 and higher)

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

### Syntax

```
CALL mysql.rds_set_source_auto_position (auto_position_mode);
```

### Parameters

*auto\_position\_mode*

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

### Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The administrative user must run the `mysql.rds_set_source_auto_position` procedure.

## mysql.rds\_set\_external\_master\_with\_auto\_position (Aurora MySQL version 1 and 2)

Configures an Aurora MySQL primary instance to accept incoming replication from an external MySQL instance. This procedure also configures replication based on global transaction identifiers (GTIDs).

This procedure is available for both RDS for MySQL and Aurora MySQL. It works differently depending on the context. When used with Aurora MySQL, this procedure doesn't configure delayed replication. This limitation is because RDS for MySQL supports delayed replication but Aurora MySQL doesn't.

### Syntax

```
CALL mysql.rds_set_external_master_with_auto_position (
  host_name
, host_port
, replication_user_name
, replication_user_password
, ssl_encryption
);
```

### Parameters

*host\_name*

The host name or IP address of the MySQL instance running external to Aurora to become the replication master.

*host\_port*

The port used by the MySQL instance running external to Aurora to be configured as the replication master. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

*replication\_user\_name*

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Aurora. We recommend that you provide an account that is used solely for replication with the external instance.

*replication\_user\_password*

The password of the user ID specified in *replication\_user\_name*.

*ssl\_encryption*

This option is not currently implemented. The default is 0.

## Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The master user must run the `mysql.rds_set_external_master_with_auto_position` procedure. The master user runs this procedure on the primary instance of an Aurora MySQL DB cluster that acts as a replication target. This can be the replication target of an external MySQL DB instance or an Aurora MySQL DB cluster.

For Aurora, this procedure is supported for Aurora MySQL version 2.04 and later MySQL 5.7-compatible versions. GTID-based replication isn't supported for Aurora MySQL 1.1 or 1.0. For Aurora MySQL version 3, use the procedure `mysql.rds_set_external_source_with_auto_position` instead.

Before you run `mysql.rds_set_external_master_with_auto_position`, configure the external MySQL DB instance to be a replication master. To connect to the external MySQL instance, specify values for *replication\_user\_name* and *replication\_user\_password*. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external MySQL instance.

### To configure an external MySQL instance as a replication master

1. Using the MySQL client of your choice, connect to the external MySQL instance and create a user account to be used for replication. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
```

2. On the external MySQL instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl\_user' user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY 'SomePassW0rd'
```

When you call `mysql.rds_set_external_master_with_auto_position`, Amazon RDS records certain information. This information is the time, the user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

To skip a specific GTID-based transaction that is known to cause a problem, you can use the [mysql.rds\\_skip\\_transaction\\_with\\_gtid \(p. 989\)](#) stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication for Amazon Aurora MySQL \(p. 863\)](#).

## Examples

When run on an Aurora primary instance, the following example configures the Aurora cluster to act as a read replica of an instance of MySQL running external to Aurora.

```
call mysql.rds_set_external_master_with_auto_position(
    'Externaldb.some.com',
    3306,
    'repl_user'@'mydomain.com',
    'SomePassW0rd');
```

## [mysql.rds\\_set\\_external\\_source\\_with\\_auto\\_position \(Aurora MySQL version 3 and higher\)](#)

Configures an Aurora MySQL primary instance to accept incoming replication from an external MySQL instance. This procedure also configures replication based on global transaction identifiers (GTIDs).

This procedure is available for both RDS for MySQL and Aurora MySQL. It works differently depending on the context. When used with Aurora MySQL, this procedure doesn't configure delayed replication. This limitation is because RDS for MySQL supports delayed replication but Aurora MySQL doesn't.

## Syntax

```
CALL mysql.rds_set_external_source_with_auto_position (
    host_name
    , host_port
    , replication_user_name
    , replication_user_password
    , ssl_encryption
);
```

## Parameters

### *host\_name*

The host name or IP address of the MySQL instance running external to Aurora to become the replication source.

### *host\_port*

The port used by the MySQL instance running external to Aurora to be configured as the replication source. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

### *replication\_user\_name*

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Aurora. We recommend that you provide an account that is used solely for replication with the external instance.

### *replication\_user\_password*

The password of the user ID specified in *replication\_user\_name*.

### *ssl\_encryption*

This option is not currently implemented. The default is 0.

## Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The administrative user must run the `mysql.rds_set_external_source_with_auto_position` procedure. The administrative user runs this procedure on the primary instance of an Aurora MySQL DB cluster that acts as a replication target. This can be the replication target of an external MySQL DB instance or an Aurora MySQL DB cluster.

For Aurora, this procedure is supported for Aurora MySQL version 2.04 and later MySQL 5.7-compatible versions. It's also supported for Aurora MySQL version 3. GTID-based replication isn't supported for Aurora MySQL 1.1 or 1.0.

Before you run `mysql.rds_set_external_source_with_auto_position`, configure the external MySQL DB instance to be a replication source. To connect to the external MySQL instance, specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external MySQL instance.

### To configure an external MySQL instance as a replication source

1. Using the MySQL client of your choice, connect to the external MySQL instance and create a user account to be used for replication. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
```

2. On the external MySQL instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the '`repl_user`' user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY 'SomePassW0rd'
```

When you call `mysql.rds_set_external_source_with_auto_position`, Amazon RDS records certain information. This information is the time, the user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

To skip a specific GTID-based transaction that is known to cause a problem, you can use the [mysql.rds\\_skip\\_transaction\\_with\\_gtid \(p. 989\)](#) stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication for Amazon Aurora MySQL \(p. 863\)](#).

## Examples

When run on an Aurora primary instance, the following example configures the Aurora cluster to act as a read replica of an instance of MySQL running external to Aurora.

```
call mysql.rds_set_external_source_with_auto_position(  
    'Externaldb.some.com',  
    3306,  
    'repl_user'@'mydomain.com',  
    'SomePassW0rd');
```

## [mysql.rds\\_skip\\_transaction\\_with\\_gtid](#)

Skips replication of a transaction with the specified global transaction identifier (GTID) on an Aurora primary instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

## Syntax

```
CALL mysql.rds_skip_transaction_with_gtid (gtid_to_skip);
```

## Parameters

*gtid\_to\_skip*

The GTID of the replication transaction to skip.

## Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The master user must run the `mysql.rds_skip_transaction_with_gtid` procedure.

For Aurora, this procedure is supported for Aurora MySQL version 2.04 and later MySQL 5.7-compatible versions. It's also supported for Aurora MySQL version 3. GTID-based replication isn't supported for Aurora MySQL 1.1 or 1.0.

# Database engine updates for Amazon Aurora MySQL

Amazon Aurora releases updates regularly. Updates are applied to Aurora DB clusters during system maintenance windows. The timing when updates are applied depends on the region and maintenance window setting for the DB cluster, as well as the type of update.

Amazon Aurora releases are made available to all AWS Regions over the course of multiple days. Some Regions might temporarily show an engine version that isn't available in a different Region yet.

Updates are applied to all instances in a DB cluster at the same time. An update requires a database restart on all instances in a DB cluster, so you experience 20 to 30 seconds of downtime, after which you can resume using your DB cluster or clusters. You can view or change your maintenance window settings from the [AWS Management Console](#).

For details about the Aurora MySQL versions that are supported by Amazon Aurora, see the [Release Notes for Aurora MySQL](#).

Following, you can learn how to choose the right Aurora MySQL version for your cluster, how to specify the version when you create or upgrade a cluster, and the procedures to upgrade a cluster from one version to another with minimal interruption.

- [MySQL bugs fixed by Aurora MySQL database engine updates \(p. 1017\)](#)

- [Security vulnerabilities fixed in Amazon Aurora MySQL \(p. 1017\)](#)

## Aurora MySQL version numbers and special versions

Although Aurora MySQL-Compatible Edition is compatible with the MySQL database engines, Aurora MySQL includes features and bug fixes that are specific to particular Aurora MySQL versions. Application developers can check the Aurora MySQL version in their applications by using SQL. Database administrators can check and specify Aurora MySQL versions when creating or upgrading Aurora MySQL DB clusters and DB instances.

### Topics

- [Checking or specifying Aurora MySQL engine versions through AWS \(p. 991\)](#)
- [Checking Aurora MySQL versions using SQL \(p. 992\)](#)

## Checking or specifying Aurora MySQL engine versions through AWS

When you perform administrative tasks using the AWS Management Console, AWS CLI, or RDS API, you specify the Aurora MySQL version in a descriptive alphanumeric format.

Starting with Aurora MySQL 2.03.2 and 1.17.9, Aurora engine versions have the following syntax.

```
mysql-major-version.mysql_aurora.aurora-mysql-version
```

The *mysql-major-version-* portion is 5 . 6, 5 . 7, or 8 . 0. This value represents the version of the client protocol and general level of MySQL feature support for the corresponding Aurora MySQL version.

The *aurora-mysql-version* is a dotted value with three parts: the Aurora MySQL major version, the Aurora MySQL minor version, and the patch level. The major version is 1, 2, or 3. Those values represent Aurora MySQL compatible with MySQL 5.6, 5.7, or 8.0 respectively. The minor version represents the feature release within the 1.x, 2.x, or 3.x series. The patch level begins at 0 for each minor version, and represents the set of subsequent bug fixes that apply to the minor version. Occasionally, a new feature is incorporated into a minor version but not made visible immediately. In these cases, the feature undergoes fine-tuning and is made public in a later patch level.

All 1.x Aurora MySQL engine versions are wire-compatible with Community MySQL 5.6.10a. All 2.x Aurora MySQL engine versions are wire-compatible with Community MySQL 5.7.12. All 3.x Aurora MySQL engine versions are wire-compatible with MySQL 8.0.23 onwards. You can refer to release notes of specific 3.x version to find the corresponding MySQL compatible version.

For example, the engine versions for Aurora MySQL 3.02.0, 2.03.2, and 1.17.9 are the following.

```
8.0.mysql_aurora.3.02.0
5.7.mysql_aurora.2.03.2
5.6.mysql_aurora.1.17.9
```

### Note

There isn't a one-to-one correspondence between community MySQL versions and the Aurora MySQL 1.x and 2.x versions. For Aurora MySQL version 3, there is a more direct mapping. To check which bug fixes and new features are in a particular Aurora MySQL release, see [Database engine updates for Amazon Aurora MySQL version 3](#), [Database engine updates for Amazon](#)

Aurora MySQL version 2 and [Database engine updates for Amazon Aurora MySQL version 1](#) in the *Release Notes for Aurora MySQL*. For a chronological list of new features and releases, see [Document history \(p. 1771\)](#). To check the minimum version required for a security-related fix, see [Security vulnerabilities fixed in Aurora MySQL](#) in the *Release Notes for Aurora MySQL*.

For Aurora MySQL 2.x, all versions 2.03.1 and lower are represented by the engine version 5.7.12. In the same way, all versions before 1.17.9 are represented by the engine version 5.6.10a. These older version designations don't include the 5.7.mysql\_aurora prefix. When you specified 5.7.12 or 5.6.10a while creating or modifying a cluster, you got the highest version before the 2.03.2 and 1.17.9 versions where the version numbering changed. To determine the exact version number for those older versions, you used the SQL technique explained in [Checking Aurora MySQL versions using SQL \(p. 992\)](#).

You specify the Aurora MySQL engine version in some AWS CLI commands and RDS API operations. For example, you specify the --engine-version option when you run the AWS CLI commands [create-db-cluster](#) and [modify-db-cluster](#). You specify the EngineVersion parameter when you run the RDS API operations [CreateDBCluster](#) and [ModifyDBCluster](#).

In Aurora MySQL 1.17.9 and higher or 2.03.2 and higher, the engine version in the AWS Management Console also includes the Aurora version. Upgrading the cluster changes the displayed value. This change helps you to specify and check the precise Aurora MySQL versions, without the need to connect to the cluster or run any SQL commands.

**Tip**

For Aurora clusters managed through AWS CloudFormation, this change in the EngineVersion setting can trigger actions by AWS CloudFormation. For information about how AWS CloudFormation treats changes to the EngineVersion setting, see the [AWS CloudFormation documentation](#).

Before Aurora MySQL 1.17.9 and 2.03.2, the process to update the engine version is to use the **Apply a Pending Maintenance Action** option for the cluster. This process doesn't change the Aurora MySQL engine version that the console displays. For example, suppose that you see an Aurora MySQL cluster with a reported engine version of 5.6.10a or 5.7.12. To find out the specific version, connect to the cluster and query the AURORA\_VERSION system variable as described previously.

## Checking Aurora MySQL versions using SQL

The Aurora version numbers that you can retrieve in your application using SQL queries use the format <major version>. <minor version>. <patch version>. You can get this version number for any DB instance in your Aurora MySQL cluster by querying the AURORA\_VERSION system variable. To get this version number, use one of the following queries.

```
select aurora_version();
select @@aurora_version;
```

Those queries produce output similar to the following.

```
mysql> select aurora_version(), @@aurora_version;
+-----+-----+
| aurora_version() | @@aurora_version |
+-----+-----+
| 2.08.1           | 2.08.1          |
+-----+-----+
```

The version numbers that the console, CLI, and RDS API return by using the techniques described in [Checking or specifying Aurora MySQL engine versions through AWS \(p. 991\)](#) are typically more descriptive. However, for versions before 2.03.2 and 1.19, AWS always returns the version numbers 5.7.12 or 5.6.10a. For those older versions, use the SQL technique to check the precise version number.

## Aurora MySQL long-term support (LTS) releases

Each new Aurora MySQL version remains available for a certain amount of time for you to use when you create or upgrade a DB cluster. After this period, you must upgrade any clusters that use that version. You can manually upgrade your cluster before the support period ends, or Aurora can automatically upgrade it for you when its Aurora MySQL version is no longer supported.

Aurora designates certain Aurora MySQL versions as long-term support (LTS) releases. DB clusters that use LTS releases can stay on the same version longer and undergo fewer upgrade cycles than clusters that use non-LTS releases. Aurora supports each LTS release for at least three years after that release becomes available. When a DB cluster that's on an LTS release is required to upgrade, Aurora upgrades it to the next LTS release. That way, the cluster doesn't need to be upgraded again for a long time.

During the lifetime of an Aurora MySQL LTS release, new patch levels introduce fixes to important issues. The patch levels don't include any new features. You can choose whether to apply such patches to DB clusters running the LTS release. For certain critical fixes, Amazon might perform a managed upgrade to a patch level within the same LTS release. Such managed upgrades are performed automatically within the cluster maintenance window.

We recommend that you upgrade to the latest release, instead of using the LTS release, for most of your Aurora MySQL clusters. Doing so takes advantage of Aurora as a managed service and gives you access to the latest features and bug fixes. The LTS releases are intended for clusters with the following characteristics:

- You can't afford downtime on your Aurora MySQL application for upgrades outside of rare occurrences for critical patches.
- The testing cycle for the cluster and associated applications takes a long time for each update to the Aurora MySQL database engine.
- The database version for your Aurora MySQL cluster has all the DB engine features and bug fixes that your application needs.

The current LTS releases for Aurora MySQL are the following:

- Aurora MySQL version 2.07.\*. For more details about this version, see [Aurora MySQL database engine updates 2021-11-24 \(version 2.07.7\)](#) in the *Release Notes for Aurora MySQL*.
- Aurora MySQL version 1.22.\*. For more details about this version, see [Aurora MySQL database engine updates 2021-06-03 \(version 1.22.5\)](#) in the *Release Notes for Aurora MySQL*.

These older versions are also designated as LTS releases:

- Aurora MySQL version 2.04.
- Aurora MySQL version 1.19.

## Upgrade paths between 5.6-compatible and 5.7-compatible clusters

For most Aurora MySQL 1.x and 2.x versions, you can upgrade a MySQL 5.6-compatible cluster to any version of a MySQL 5.7-compatible cluster.

However, if your cluster is running Aurora MySQL 1.23 or higher, any upgrade to Aurora MySQL version 2.x must be to Aurora MySQL 2.09 or higher. This restriction applies even when you upgrade by restoring a snapshot to create a new Aurora cluster. Aurora MySQL 1.23 includes improvements in Aurora storage. For example, the maximum size of the cluster volume is larger in Aurora MySQL 1.23 and later. Aurora MySQL 2.09 is the first 2.x version that has the same storage enhancements.

## Preparing for Amazon Aurora MySQL-Compatible Edition version 1 end of life

Amazon Aurora MySQL-Compatible Edition version 1 (with MySQL 5.6 compatibility) is planned to reach end of life on February 28, 2023. Amazon advises that you upgrade all clusters (provisioned and Aurora Serverless) running Aurora MySQL version 1 to Aurora MySQL version 2 (with MySQL 5.7 compatibility) or Aurora MySQL version 3 (with MySQL 8.0 compatibility). Do this before Aurora MySQL version 1 reaches the end of its support period.

For Aurora provisioned DB clusters, you can complete upgrades from Aurora MySQL version 1 to Aurora MySQL version 2 by several methods. You can find instructions for the in-place upgrade mechanism in [How to perform an in-place upgrade \(p. 1006\)](#). Another way to complete the upgrade is to take a snapshot of an Aurora MySQL version 1 cluster and restore the snapshot to an Aurora MySQL version 2 cluster. Or you can follow a multistep process that runs the old and new clusters side by side. For more details about each method, see [Upgrading from Aurora MySQL 1.x to 2.x \(p. 1002\)](#)

For Aurora Serverless v1 DB clusters, you can perform an in-place upgrade from Aurora MySQL version 1 to Aurora MySQL version 2. For more details about this method, see [Modifying an Aurora Serverless v1 DB cluster \(p. 1570\)](#).

For Aurora provisioned DB clusters, you can complete upgrades from Aurora MySQL version 1 to Aurora MySQL version 3 by using a two-stage upgrade process. The first stage requires an upgrade from Aurora MySQL version 1 to Aurora MySQL version 2 using the methods described preceding. The second stage requires an upgrade from Aurora MySQL version 2 to Aurora MySQL version 3. To perform this upgrade, take a snapshot of an Aurora MySQL version 2 cluster and restore the snapshot to an Aurora MySQL version 3 cluster. For more details, see [Upgrading from Aurora MySQL 2.x to 3.x \(p. 1002\)](#). Please note the [Feature differences between Aurora MySQL version 2 and 3 \(p. 658\)](#).

You can find upcoming end-of-life dates for Aurora major versions in [Amazon Aurora versions \(p. 5\)](#). Amazon automatically upgrades any clusters that you don't upgrade yourself before the end-of-life date. After the end-of-life date, these automatic upgrades to the subsequent major version occur during a scheduled maintenance window for clusters.

The following are additional milestones for upgrading Aurora MySQL version 1 clusters (provisioned and Aurora Serverless) that are reaching end of life. For each, the start time is 00:00 Universal Coordinated Time (UTC).

1. Now through February 28, 2023 – You can at any time start upgrades of Aurora MySQL version 1 (with MySQL 5.6 compatibility) clusters to Aurora MySQL version 2 (with MySQL 5.7 compatibility). From Aurora MySQL version 2, you can do a further upgrade to Aurora MySQL version 3 (with MySQL 8.0 compatibility) for Aurora provisioned DB clusters.
2. September 27, 2022 – After this time, you can't create new Aurora MySQL version 1 clusters or instances from either the AWS Management Console or the AWS Command Line Interface (AWS CLI). You also can't add new Secondary Regions to an Aurora global database. This might affect your ability to recover from an unplanned outage as outlined in [Recovering an Amazon Aurora global database from an unplanned outage \(p. 193\)](#), because you can't complete steps 5 and 6 after this time. You will also be unable to create a new cross-Region read replica running Aurora MySQL version 1. You can still do the following for existing Aurora MySQL version 1 clusters until February 28, 2023:
  - Restore a snapshot taken of an Aurora MySQL version 1 cluster.
  - Add read replicas (not applicable for Aurora Serverless DB clusters).
  - Change instance configuration.
  - Perform point-in-time restore.
  - Create clones of existing version 1 clusters.
  - Create a new cross-Region read replica running Aurora MySQL version 2 or higher.

3. February 28, 2023 – After this time, we plan to automatically upgrade Aurora MySQL version 1 clusters to the default version of Aurora MySQL version 2 within a scheduled maintenance window that follows. Restoring Aurora MySQL version 1 DB snapshots results in an automatic upgrade of the restored cluster to the default version of Aurora MySQL version 2 at that time.

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time. After the upgrade is finished, you also might have follow-up work to do. For example, you might need to follow up due to differences in SQL compatibility, the way certain MySQL-related features work, or parameter settings between the old and new versions.

To learn more about the methods, planning, testing, and troubleshooting of Aurora MySQL major version upgrades, be sure to thoroughly read [Upgrading the major version of an Aurora MySQL DB cluster \(p. 1001\)](#).

## Finding clusters affected by this end-of-life process

To find clusters affected by this end-of-life process, use the following procedures.

### Important

Be sure to perform these instructions in every AWS Region where your resources are located.

### Console

#### To find an Aurora MySQL version 1 cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. In the **Filter by databases** box, enter **5.6**.
4. Check for Aurora MySQL in the engine column.

### AWS CLI

To find clusters affected by this end-of-life process using the AWS CLI, call the [describe-db-clusters](#) command. You can use the sample script following.

### Example

```
aws rds describe-db-clusters --include-share --query 'DBClusters[?Engine==`aurora`].{EV:EngineVersion, DBCI:DBClusterIdentifier, EM:EngineMode}' --output table --region us-east-1

+-----+-----+
|       DescribeDBClusters      |
+-----+-----+
|   DBCI    |   EM    |   EV    |
+-----+-----+-----+
| my-database-1| serverless | 5.6.10a |
+-----+-----+
```

### RDS API

To find Aurora MySQL DB clusters running Aurora MySQL version 1, use the RDS [DescribeDBClusters](#) API operation with the following required parameters:

- **DescribeDBClusters**

- Filters.Filter.N
  - Name
    - engine
  - Values.Value.N
    - ['aurora']

## Upgrading Amazon Aurora MySQL DB clusters

You can upgrade an Aurora MySQL DB cluster to get bug fixes, new Aurora MySQL features, or to change to an entirely new version of the underlying database engine. The following sections show how.

### Tip

The type of upgrade that you do depends on how much downtime you can afford for your cluster, how much verification testing you plan to do, how important the specific bug fixes or new features are for your use case, and whether you plan to do frequent small upgrades or occasional upgrades that skip several intermediate versions. For each upgrade, you can change the major version, the minor version, and the patch level for your cluster. If you aren't familiar with the distinction between Aurora MySQL major versions, minor versions, and patch levels, you can read the background information at [Aurora MySQL version numbers and special versions \(p. 991\)](#).

### Topics

- [Upgrading the minor version or patch level of an Aurora MySQL DB cluster \(p. 996\)](#)
- [Upgrading the major version of an Aurora MySQL DB cluster \(p. 1001\)](#)

## Upgrading the minor version or patch level of an Aurora MySQL DB cluster

You can use the following methods to upgrade the minor version of a DB cluster or to patch a DB cluster:

- [Upgrading Aurora MySQL by modifying the engine version \(p. 996\)](#) (for Aurora MySQL 1.19.0 and higher, or 2.03.2 and higher)
- [Enabling automatic upgrades between minor Aurora MySQL versions \(p. 997\)](#)
- [Upgrading Aurora MySQL by applying pending maintenance to an Aurora MySQL DB cluster \(p. 998\)](#) (before Aurora MySQL 1.19.0)

For information about how zero-downtime patching can reduce interruptions during the upgrade process, see [Using zero-downtime patching \(p. 999\)](#).

### Upgrading Aurora MySQL by modifying the engine version

Upgrading the minor version of an Aurora MySQL cluster applies additional fixes and new features to an existing cluster. You can do this type of upgrade for clusters that are running Amazon Aurora MySQL version 1.19.0 and higher, or 2.03.2 and higher.

This kind of upgrade applies to Aurora MySQL clusters where the original version and the upgraded version are both in the Aurora MySQL 1.x series, or both in the Aurora MySQL 2.x series. The process is fast and straightforward because it doesn't involve any conversion for the Aurora MySQL metadata or reorganization of your table data.

You perform this kind of upgrade by modifying the engine version of the DB cluster using the AWS Management Console, AWS CLI, or the RDS API. If your cluster is running Aurora MySQL 1.x, choose a higher 1.x version. If your cluster is running Aurora MySQL 2.x, choose a higher 2.x version.

**Note**

If you're performing a minor upgrade on an Aurora global database, upgrade all of the secondary clusters before you upgrade the primary cluster.

**To modify the engine version of a DB cluster**

- **By using the console** – Modify the properties of your cluster. In the **Modify DB cluster** window, change the Aurora MySQL engine version in the **DB engine version** box. If you aren't familiar with the general procedure for modifying a cluster, follow the instructions at [Modifying the DB cluster by using the console, CLI, and API \(p. 248\)](#).
- **By using the AWS CLI** – Call the `modify-db-cluster` AWS CLI command, and specify the name of your DB cluster for the `--db-cluster-identifier` option and the engine version for the `--engine-version` option.

For example, to upgrade to Aurora MySQL version 2.03.2, set the `--engine-version` option to `5.7.mysql_aurora.2.03.2`. Specify the `--apply-immediately` option to immediately update the engine version for your DB cluster.

- **By using the RDS API** – Call the `ModifyDBCluster` API operation, and specify the name of your DB cluster for the `DBClusterIdentifier` parameter and the engine version for the `EngineVersion` parameter. Set the `ApplyImmediately` parameter to `true` to immediately update the engine version for your DB cluster.

**Enabling automatic upgrades between minor Aurora MySQL versions**

For an Amazon Aurora MySQL DB cluster, you can specify that Aurora upgrades the DB cluster automatically to new minor versions. You do so by using the automatic minor version upgrade property of the DB cluster using the AWS Management Console, AWS CLI, or the RDS API.

The automatic upgrades occur during the maintenance window for the database.

Automatic minor version upgrade doesn't apply to the following kinds of Aurora MySQL clusters:

- Multi-master clusters.
- Clusters that are part of an Aurora global database.
- Clusters that have cross-Region replicas.

The outage duration varies depending on workload, cluster size, the amount of binary log data, and if Aurora can use the zero-downtime patching (ZDP) feature. Aurora restarts the database cluster, so you might experience a short period of unavailability before resuming use of your cluster. In particular, the amount of binary log data affects recovery time. The DB instance processes the binary log data during recovery. Thus, a high volume of binary log data increases recovery time.

**To enable automatic minor version upgrades for an Aurora MySQL DB cluster**

1. Follow the general procedure to modify the DB instances in your cluster, as described in [Modify a DB instance in a DB cluster \(p. 249\)](#). Repeat this procedure for each DB instance in your cluster.
2. Do the following to enable automatic minor version upgrades for your cluster:
  - **By using the console** – Complete the following steps:
    1. Sign in to the Amazon RDS console. Choose **Databases**, and find the DB cluster where you want to turn automatic minor version upgrade on or off.
    2. Choose each DB instance in the DB cluster that you want to modify. Apply the following change for each DB instance in sequence:
      - a. Choose **Modify**.

- b. Choose the **Enable auto minor version upgrade** setting. This setting is part of the **Maintenance** section.
  - c. Choose **Continue** and check the summary of modifications.
  - d. (Optional) Choose **Apply immediately** to apply the changes immediately.
  - e. On the confirmation page, choose **Modify DB instance**.
- **By using the AWS CLI** – Call the [modify-db-instance](#) AWS CLI command. Specify the name of your DB instance for the `--db-instance-identifier` option and `true` for the `--auto-minor-version-upgrade` option. Optionally, specify the `--apply-immediately` option to immediately enable this setting for your DB instance. Run a separate `modify-db-instance` command for each DB instance in the cluster.
  - **By using the RDS API** – Call the [ModifyDBInstance](#) API operation and specify the name of your DB cluster for the `DBClusterIdentifier` parameter and `true` for the `AutoMinorVersionUpgrade` parameter. Optionally, set the `ApplyImmediately` parameter to `true` to immediately enable this setting for your DB instance. Call a separate `ModifyDBInstance` operation for each DB instance in the cluster.

You can use a CLI command such as the following to check the status of the **Enable auto minor version upgrade** for all of the DB instances in your Aurora MySQL clusters.

```
aws rds describe-db-instances \
--query '*[]'.
{DBClusterIdentifier:DBClusterIdentifier,DBInstanceIdentifier:DBInstanceIdentifier,AutoMinorVersionUpgr...
```

That command produces output similar to the following:

```
[  
 {  
     "DBInstanceIdentifier": "db-t2-medium-instance",  
     "DBClusterIdentifier": "cluster-57-2020-06-03-6411",  
     "AutoMinorVersionUpgrade": true  
 },  
 {  
     "DBInstanceIdentifier": "db-t2-small-original-size",  
     "DBClusterIdentifier": "cluster-57-2020-06-03-6411",  
     "AutoMinorVersionUpgrade": false  
 },  
 {  
     "DBInstanceIdentifier": "instance-2020-05-01-2332",  
     "DBClusterIdentifier": "cluster-57-2020-05-01-4615",  
     "AutoMinorVersionUpgrade": true  
 },  
 ... output omitted ...
```

## Upgrading Aurora MySQL by applying pending maintenance to an Aurora MySQL DB cluster

When upgrading to Aurora MySQL version 1.x versions, new database engine minor versions and patches show as an **available** maintenance upgrade for your DB cluster. You can upgrade or patch the database version of your DB cluster by applying the available maintenance action. We recommend applying the update on a nonproduction DB cluster first, so that you can see how changes in the new version affect your instances and applications.

### To apply pending maintenance actions

- **By using the console** – Complete the following steps:

1. Sign in to the Amazon RDS console, choose **Databases**, and choose the DB cluster that shows the **available** maintenance upgrade.
  2. For **Actions**, choose **Upgrade now** to immediately update the database version for your DB cluster, or **Upgrade at next window** to update the database version for your DB cluster during the next DB cluster maintenance window.
- **By using the AWS CLI** – Call the [apply-pending-maintenance-action](#) AWS CLI command, and specify the Amazon Resource Name (ARN) for your DB cluster for the `--resource-id` option and `system-update` for the `--apply-action` option. Set the `--opt-in-type` option to `immediate` to immediately update the database version for your DB cluster, or `next-maintenance` to update the database version for your DB cluster during the next cluster maintenance window.
  - **By using the RDS API** – Call the [ApplyPendingMaintenanceAction](#) API operation, and specify the ARN for your DB cluster for the `ResourceId` parameter and `system-update` for the `ApplyAction` parameter. Set the `OptInType` parameter to `immediate` to immediately update the database version for your DB cluster, or `next-maintenance` to update the database version for your instance during the next cluster maintenance window.

For more information on how Amazon RDS manages database and operating system updates, see [Maintaining an Amazon Aurora DB cluster \(p. 321\)](#).

**Note**

If your current Aurora MySQL version is 1.14.x but lower than 1.14.4, you can upgrade only to 1.14.4 (which supports db.r4 instance classes). Also, to upgrade from 1.14.x to a higher minor Aurora MySQL version, such as 1.17, the 1.14.x version must be 1.14.4.

## Using zero-downtime patching

Performing upgrades for Aurora MySQL DB clusters involves the possibility of an outage when the database is shut down and while it's being upgraded. By default, if you start the upgrade while the database is busy, you lose all the connections and transactions that the DB cluster is processing. If you wait until the database is idle to perform the upgrade, you might have to wait a long time.

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an Aurora MySQL upgrade. If ZDP completes successfully, application sessions are preserved and the database engine restarts while the upgrade is in progress. The database engine restart can cause a drop in throughput lasting for a few seconds to approximately one minute.

The following table shows the Aurora MySQL versions and DB instance classes where ZDP is available.

Version	db.r* instance classes	db.t* instance classes	db.serverless instance class
2.07.2 and higher 2.07 versions	No	Yes	N/A
2.10.0 and higher 2.10 versions	Yes	Yes	N/A
3.01.0 and 3.01.1	Yes	Yes	N/A
3.02.0 and higher 3.x versions	Yes	Yes	Yes

You can see metrics of important attributes during ZDP in the MySQL error log. You can also see information about when Aurora MySQL uses ZDP or chooses not to use ZDP on the **Events** page in the AWS Management Console.

In Aurora MySQL version 2.10 and higher and version 3, Aurora can perform a zero-downtime patch when binary log replication is enabled. Aurora MySQL automatically drops the connection to the binlog target during a ZDP operation. Aurora MySQL automatically reconnects to the binlog target and resumes replication after the restart finishes.

ZDP also works in combination with the reboot enhancements in Aurora MySQL 2.10 and higher. Patching the writer DB instance automatically patches readers at the same time. After performing the patch, Aurora restores the connections on both the writer and reader DB instances. Before Aurora MySQL 2.10, ZDP applies only to the writer DB instance of a cluster.

ZDP might not complete successfully under the following conditions:

- Long-running queries or transactions are in progress. If Aurora can perform ZDP in this case, any open transactions are canceled.
- Open Secure Socket Layer (SSL) connections exist.
- Temporary tables or table locks are in use, for example while data definition language (DDL) statements run. If Aurora can perform ZDP in this case, any open transactions are canceled.
- Pending parameter changes exist.

If no suitable time window for performing ZDP becomes available because of one or more of these conditions, patching reverts to the standard behavior.

Although connections remain intact following a successful ZDP operation, some variables and features are reinitialized. The following kinds of information aren't preserved through a restart caused by zero-downtime patching:

- Global variables. Aurora restores session variables, but it doesn't restore global variables after the restart.
- Status variables. In particular, the uptime value reported by the engine status is reset after a restart that uses the ZDR or ZDP mechanisms.
- LAST\_INSERT\_ID.
- In-memory auto\_increment state for tables. The in-memory auto-increment state is reinitialized. For more information about auto-increment values, see [MySQL Reference Manual](#).
- Diagnostic information from INFORMATION\_SCHEMA and PERFORMANCE\_SCHEMA tables. This diagnostic information also appears in the output of commands such as SHOW PROFILE and SHOW PROFILES.

The following activities related to zero-downtime restart are reported on the **Events** page:

- Attempting to upgrade the database with zero downtime.
- Attempt to upgrade the database with zero downtime finished. The event reports how long the process took. The event also reports how many connections were preserved during the restart and how many connections were dropped. You can consult the database error log to see more details about what happened during the restart.

The following table summarizes how ZDP works for upgrading from and to specific Aurora MySQL 1.x and 2.x versions. The instance class of the DB instance also affects whether Aurora uses the ZDP mechanism.

Original version	Upgraded version	Does ZDP apply?
Aurora MySQL 1.*	Any	No

Original version	Upgraded version	Does ZDP apply?
Aurora MySQL 2.*, before 2.07.2	Any	No
Aurora MySQL 2.07.2, 2.07.3	2.07.4 and higher 2.07 versions, 2.10.*	Yes, on the writer instance for T2 and T3 instance classes only. Aurora only performs ZDP if a quiet point is found before a timeout occurs. After the timeout, Aurora performs a regular restart.
Aurora MySQL 2.07.4 and higher 2.07 versions	2.10.*	Yes, on the writer instance for T2 and T3 instances only. Aurora rolls back transactions for active and idle transactions. Connections using SSL, temporary tables, table locks, or user locks are disconnected. Aurora might restart the engine and drop all connections if the engine takes too long to start after ZDP finishes.
Aurora MySQL 2.10.*	2.10.*	Yes, on the writer instance for db.t* and db.r* instances. Aurora rolls back transactions for active and idle transactions. Connections using SSL, temporary tables, table locks, or user locks are disconnected. Aurora might restart the engine and drop all connections if the engine takes too long to start after ZDP finishes.

## Alternative blue-green upgrade technique

Blog post: [Performing major version upgrades for Aurora MySQL with minimum downtime](#).

## Upgrading the major version of an Aurora MySQL DB cluster

In an Aurora MySQL version number such as 2.08.1, the 2 represents the major version. Aurora MySQL version 1 is compatible with MySQL 5.6. Aurora MySQL version 2 is compatible with MySQL 5.7. Aurora MySQL version 3 is compatible with MySQL 8.0.23.

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time. After the upgrade is finished, you also might have followup work to do. For example, this might occur due to differences in SQL compatibility, the way certain MySQL-related features work, or parameter settings between the old and new versions.

## Upgrading from Aurora MySQL 2.x to 3.x

Currently, upgrading to Aurora MySQL version 3 requires restoring a snapshot of an Aurora MySQL version 2 cluster to create a new version 3 cluster. If your original cluster is running Aurora MySQL version 1, you first upgrade to version 2 and then use the snapshot restore technique to create the version 3 cluster. For general information about Aurora MySQL version 3 and the new features that you can use after you upgrade, see [Aurora MySQL version 3 compatible with MySQL 8.0 \(p. 653\)](#). For details and examples of performing this type of upgrade, see [Upgrade planning for Aurora MySQL version 3 \(p. 667\)](#) and [Upgrading to Aurora MySQL version 3 \(p. 666\)](#).

### Tip

When you upgrade the major version of your cluster from 2.x to 3.x, the original cluster and the upgraded one both use the same `aurora-mysql` value for the `engine` attribute.

## Upgrading from Aurora MySQL 1.x to 2.x

Upgrading the major version from 1.x to 2.x changes the `engine` attribute of the cluster from `aurora` to `aurora-mysql`. Make sure to update any AWS CLI or API automation that you use with this cluster to account for the changed `engine` value.

If you have a MySQL 5.6-compatible cluster and want to upgrade it to a MySQL-5.7 compatible cluster, you can do so by running an upgrade process on the cluster itself. This kind of upgrade is an *in-place upgrade*, in contrast to upgrades that you do by creating a new cluster. This technique keeps the same endpoint and other characteristics of the cluster. The upgrade is relatively fast because it doesn't require copying all your data to a new cluster volume. This stability helps to minimize any configuration changes in your applications. It also helps to reduce the amount of testing for the upgraded cluster, because the number of DB instances and their instance classes all stay the same.

The in-place upgrade mechanism involves shutting down your DB cluster while the operation takes place. Aurora performs a clean shutdown and completes outstanding operations such as transaction rollback and undo purge.

The in-place upgrade is convenient, because it is simple to perform and minimizes configuration changes to associated applications. For example, an in-place upgrade preserves the endpoints and set of DB instances for your cluster. However, the time needed for an in-place upgrade can vary depending on the properties of your schema and how busy the cluster is. Thus, depending on the needs for your cluster, you can choose between in-place upgrade, snapshot restore as described in [Restoring from a DB cluster snapshot \(p. 375\)](#), or other upgrade techniques such as the one described in [Alternative blue-green upgrade technique \(p. 1016\)](#).

If your cluster is running a version that's lower than 1.22.3, the upgrade might take longer because Aurora MySQL automatically performs an upgrade to 1.22.3 as a first step. To minimize downtime during the major version upgrade, you can do an initial minor version upgrade to Aurora MySQL 1.22.3 in advance.

## Planning a major version upgrade for an Aurora MySQL cluster

To make sure that your applications and administration procedures work smoothly after upgrading a cluster between major versions, you can do some advance planning and preparation. To see what sorts of management code to update for your AWS CLI scripts or RDS API-based applications, see [How in-place upgrades affect the parameter groups for a cluster \(p. 1008\)](#) and [Changes to cluster properties between Aurora MySQL version 1 and 2 \(p. 1008\)](#).

You can learn the sorts of issues that you might encounter during the upgrade by reading [Troubleshooting for Aurora MySQL in-place upgrade \(p. 1010\)](#). For issues that might cause the upgrade to take a long time, you can test those conditions in advance and correct them.

To verify application compatibility, performance, maintenance procedures, and similar considerations for the upgraded cluster, you can perform a simulation of the upgrade before doing the real upgrade. This

technique can be especially useful for production clusters. Here, it's important to minimize downtime and have the upgraded cluster ready to go as soon as the upgrade is finished.

**Note**

This technique applies to upgrades from Aurora MySQL version 1 to version 2. Currently, you can't upgrade from Aurora MySQL version 2 to 3 by using cloning.

Use the following steps:

1. Create a clone of the original cluster. Follow the procedure in [Cloning a volume for an Amazon Aurora DB cluster \(p. 280\)](#).
2. Set up a similar set of writer and reader DB instances as in the original cluster.
3. Perform an in-place upgrade of the cloned cluster. Follow the procedure in [How to perform an in-place upgrade \(p. 1006\)](#). Start the upgrade immediately after creating the clone. That way, the cluster volume is still identical to the state of the original cluster. If the clone sits idle before you do the upgrade, Aurora performs database cleanup processes in the background. In that case, the upgrade of the clone isn't an accurate simulation of upgrading the original cluster.
4. Test application compatibility, performance, administration procedures, and so on, using the cloned cluster.
5. If you encounter any issues, adjust your upgrade plans to account for them. For example, adapt any application code to be compatible with the feature set of the higher version. Estimate how long the upgrade is likely to take based on the amount of data in your cluster. You might also choose to schedule the upgrade for a time when the cluster isn't busy.
6. After you are satisfied that your applications and workload work properly with the test cluster, you can perform the in-place upgrade for your production cluster.
7. To minimize the total downtime of your cluster during a major version upgrade, make sure that the workload on the cluster is low or zero at the time of the upgrade. In particular, make sure that there are no long running transactions in progress when you start the upgrade.

## Aurora MySQL major version upgrade paths

Not all kinds or versions of Aurora MySQL clusters can use the in-place upgrade mechanism. You can learn the appropriate upgrade path for each Aurora MySQL cluster by consulting the following table.

Type of Aurora MySQL DB cluster	Can it use in-place upgrade?	Action
Aurora MySQL provisioned cluster, 1.22.3 or higher	Yes	This is the fastest upgrade path. Aurora doesn't need to perform an intermediate upgrade first.
Aurora MySQL provisioned cluster, lower than 1.22.3	Yes	If your cluster is running a version that's lower than Aurora MySQL 1.22.3, the upgrade might take longer because Aurora MySQL automatically performs an upgrade to 1.22.3 as a first step. To minimize downtime during the major version upgrade, you can do an initial minor version upgrade to Aurora MySQL 1.22.3 in advance.
Aurora MySQL provisioned cluster, 2.0 or higher	No	In-place upgrade is only for 5.6-compatible Aurora MySQL clusters, to make possible compatibility with MySQL 5.7. Aurora MySQL version 2 is already compatible with 5.7. Use the procedure for upgrading the minor version or patch level to change from one 5.7-compatible version to another.

Type of Aurora MySQL DB cluster	Can it use in-place upgrade?	Action
Aurora MySQL provisioned cluster, 3.1.0 or higher	No	For information about upgrading to Aurora MySQL version 3, see <a href="#">Upgrade planning for Aurora MySQL version 3 (p. 667)</a> and <a href="#">Upgrading to Aurora MySQL version 3 (p. 666)</a> .
Aurora Serverless v1 cluster	Yes	You can upgrade from a MySQL 5.6-compatible Aurora Serverless v1 version to a MySQL 5.7-compatible one by performing an in-place upgrade. For more information, see <a href="#">Modifying an Aurora Serverless v1 DB cluster (p. 1570)</a> .
Cluster in an Aurora global database	Yes	Follow the <a href="#">procedure for doing an in-place upgrade (p. 1006)</a> for clusters in an Aurora global database. Perform the upgrade on the primary cluster in the global database. Aurora upgrades the primary cluster and all the secondary clusters in the global database at the same time. If you use the AWS CLI or RDS API, call the <code>modify-global-cluster</code> command or <code>ModifyGlobalCluster</code> operation instead of <code>modify-db-cluster</code> or <code>ModifyDBCluster</code> .
Multi-master cluster	No	Currently, multi-master replication isn't available for Aurora MySQL 5.7-compatible clusters. You also can't upgrade a multi-master cluster by performing a snapshot restore. If you need to move your data from a multi-master cluster to an Aurora MySQL 5.7-compatible or 8.0-compatible cluster, use a logical dump produced by a tool such as AWS Database Migration Service (AWS DMS) or the <code>mysqldump</code> command.
Parallel query cluster	Maybe	If you have an existing parallel query cluster using an older Aurora MySQL version, upgrade the cluster to Aurora MySQL 1.23 first. Follow the procedure in <a href="#">Upgrade considerations for parallel query (p. 802)</a> . You make some changes to configuration parameters to turn parallel query back on after this initial upgrade. Then you can perform an in-place upgrade. In this case, choose 2.09.1 or higher for the Aurora MySQL version.
Cluster that is the target of binary log replication	Maybe	If the binary log replication is from a 5.6-compatible Aurora MySQL cluster, you can perform an in-place upgrade. You can't perform the upgrade if the binary log replication is from an RDS MySQL or an on-premises MySQL DB instance. In that case, you can upgrade using the snapshot restore mechanism.

Type of Aurora MySQL DB cluster	Can it use in-place upgrade?	Action
Cluster with zero DB instances	No	<p>Using the AWS CLI or the RDS API, you can create an Aurora MySQL cluster without any attached DB instances. In the same way, you can also remove all DB instances from an Aurora MySQL cluster while leaving the data in the cluster volume intact. While a cluster has zero DB instances, you can't perform an in-place upgrade.</p> <p>The upgrade mechanism requires a writer instance in the cluster to perform conversions on the system tables, data files, and so on. In this case, use the AWS CLI or the RDS API to create a writer instance for the cluster. Then you can perform an in-place upgrade.</p>
Cluster with backtrack enabled	Yes	You can perform an in-place upgrade for an Aurora MySQL cluster that uses the backtrack feature. However, after the upgrade, you can't backtrack the cluster to a time before the upgrade.

## How the Aurora MySQL in-place major version upgrade works

Aurora MySQL performs a major version upgrade as a multistage process. You can check the current status of an upgrade. Some of the upgrade steps also provide progress information. As each stage begins, Aurora MySQL records an event. You can examine events as they occur on the **Events** page in the RDS console. For more information about working with events, see [Working with Amazon RDS event notification \(p. 572\)](#).

### Important

Once the process begins, it runs until the upgrade either succeeds or fails. You can't cancel the upgrade while it's underway. If the upgrade fails, Aurora rolls back all the changes and your cluster has the same engine version, metadata, and so on as before.

The upgrade process consists of these stages:

1. Aurora performs a series of checks before beginning the upgrade process. Your cluster keeps running while Aurora does these checks. For example, the cluster can't have any XA transactions in the prepared state or be processing any data definition language (DDL) statements. For example, you might need to shut down applications that are submitting certain kinds of SQL statements. Or you might simply wait until certain long-running statements are finished. Then try the upgrade again. Some checks test for conditions that don't prevent the upgrade but might make the upgrade take a long time.

If Aurora detects that any required conditions aren't met, modify the conditions identified in the event details. Follow the guidance in [Troubleshooting for Aurora MySQL in-place upgrade \(p. 1010\)](#). If Aurora detects conditions that might cause a slow upgrade, plan to monitor the upgrade over an extended period.

2. Aurora takes your cluster offline. Then Aurora performs a similar set of tests as in the previous stage, to confirm that no new issues arose during the shutdown process. If Aurora detects any conditions at this point that would prevent the upgrade, Aurora cancels the upgrade and brings the cluster back online. In this case, confirm when the conditions no longer apply and start the upgrade again.
3. Aurora creates a snapshot of your cluster volume. Suppose that you discover compatibility or other kinds of issues after the upgrade is finished. Or suppose that you want to perform testing using both

the original and upgraded clusters. In such cases, you can restore from this snapshot to create a new cluster with the original engine version and the original data.

**Tip**

This snapshot is a manual snapshot. However, Aurora can create it and continue with the upgrade process even if you have reached your quota for manual snapshots. This snapshot remains permanently until you delete it. After you finish all post-upgrade testing, you can delete this snapshot to minimize storage charges.

4. Aurora clones your cluster volume. Cloning is a fast operation that doesn't involve copying the actual table data. If Aurora encounters an issue during the upgrade, it reverts to the original data from the cloned cluster volume and brings the cluster back online. The temporary cloned volume during the upgrade isn't subject to the usual limit on the number of clones for a single cluster volume.
5. Aurora performs a clean shutdown for the writer DB instance. During the clean shutdown, progress events are recorded every 15 minutes for the following operations. You can examine events as they occur on the **Events** page in the RDS console.
  - Aurora purges the undo records for old versions of rows.
  - Aurora rolls back any uncommitted transactions.
6. Aurora upgrades the engine version on the writer DB instance:
  - Aurora installs the binary for the new engine version on the writer DB instance.
  - Aurora uses the writer DB instance to upgrade your data to MySQL 5.7-compatible format. During this stage, Aurora modifies the system tables and performs other conversions that affect the data in your cluster volume. In particular, Aurora upgrades the partition metadata in the system tables to be compatible with the MySQL 5.7 partition format. This stage can take a long time if the tables in your cluster have a large number of partitions.If any errors occur during this stage, you can find the details in the MySQL error logs. After this stage starts, if the upgrade process fails for any reason, Aurora restores the original data from the cloned cluster volume.
7. Aurora upgrades the engine version on the reader DB instances.
8. The upgrade process is completed. Aurora records a final event to indicate that the upgrade process completed successfully. Now your DB cluster is running the new major version.

## How to perform an in-place upgrade

### Console

#### To upgrade the major version of an Aurora MySQL DB cluster

1. (Optional) Review the background material in [How the Aurora MySQL in-place major version upgrade works \(p. 1005\)](#). Perform any pre-upgrade planning and testing, as described in [Planning a major version upgrade for an Aurora MySQL cluster \(p. 1002\)](#).
2. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
3. If you used a custom parameter group with the original 1.x cluster, create a corresponding MySQL 5.7-compatible parameter group. Make any necessary adjustments to the configuration parameters in that new parameter group. For more information, see [How in-place upgrades affect the parameter groups for a cluster \(p. 1008\)](#).
4. In the navigation pane, choose **Databases**.
5. In the list, choose the DB cluster that you want to modify.
6. Choose **Modify**.
7. For **Version**, choose an Aurora MySQL 2.x version.
8. Choose **Continue**.

9. On the next page, specify when to perform the upgrade. Choose **During the next scheduled maintenance window or Immediately**.
10. (Optional) Periodically examine the **Events** page in the RDS console during the upgrade. Doing so helps you to monitor the progress of the upgrade and identify any issues. If the upgrade encounters any issues, consult [Troubleshooting for Aurora MySQL in-place upgrade \(p. 1010\)](#) for the steps to take.
11. If you created a new MySQL 5.7-compatible parameter group at the start of this procedure, associate the custom parameter group with your upgraded cluster. For more information, see [How in-place upgrades affect the parameter groups for a cluster \(p. 1008\)](#).

**Note**

Performing this step requires you to restart the cluster again to apply the new parameter group.

12. (Optional) After you complete any post-upgrade testing, delete the manual snapshot that Aurora created at the beginning of the upgrade.

## AWS CLI

To upgrade the major version of an Aurora MySQL DB cluster, use the AWS CLI [modify-db-cluster](#) command with the following required parameters:

- `--db-cluster-identifier`
- `--engine aurora-mysql`
- `--engine-version`
- `--allow-major-version-upgrade`
- `--apply-immediately` or `--no-apply-immediately`

If your cluster uses any custom parameter groups, also include one or both of the following options:

- `--db-cluster-parameter-group-name`, if the cluster uses a custom cluster parameter group
- `--db-instance-parameter-group-name`, if any instances in the cluster use a custom DB parameter group

The following example upgrades the `sample-cluster` DB cluster to Aurora MySQL version 2.09.0. The upgrade happens immediately, instead of waiting for the next maintenance window.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier sample-cluster \
    --engine aurora-mysql \
    --engine-version 5.7.mysql_aurora.2.09.0 \
    --allow-major-version-upgrade \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier sample-cluster ^
    --engine aurora-mysql ^
    --engine-version 5.7.mysql_aurora.2.09.0 ^
```

```
--allow-major-version-upgrade ^  
--apply-immediately
```

You can combine other CLI commands with `modify-db-cluster` to create an automated end-to-end process for performing and verifying upgrades. For more information and examples, see [Aurora MySQL in-place upgrade tutorial \(p. 1011\)](#).

**Note**

If your cluster is part of an Aurora global database, the in-place upgrade procedure is slightly different. You call the `modify-global-cluster` command operation instead of `modify-db-cluster`. For more information, see [In-place major upgrades for global databases \(p. 1009\)](#).

## RDS API

To upgrade the major version of an Aurora MySQL DB cluster, use the RDS API `ModifyDBCluster` operation with the following required parameters:

- `DBClusterIdentifier`
- `Engine`
- `EngineVersion`
- `AllowMajorVersionUpgrade`
- `ApplyImmediately` (set to `true` or `false`)

**Note**

If your cluster is part of an Aurora global database, the in-place upgrade procedure is slightly different. You call the `ModifyGlobalCluster` operation instead of `ModifyDBCluster`. For more information, see [In-place major upgrades for global databases \(p. 1009\)](#).

## How in-place upgrades affect the parameter groups for a cluster

Aurora parameter groups have different sets of configuration settings for clusters that are compatible with MySQL 5.6 or 5.7. When you perform an in-place upgrade, the upgraded cluster and all its instances must use corresponding 5.7-compatible cluster and instance parameter groups. If your cluster and instances use the default 5.6-compatible parameter groups, the upgraded cluster and instance start with the default 5.7-compatible parameter groups. If your cluster and instances use any custom parameter groups, you must create corresponding 5.7-compatible parameter groups and specify those during the upgrade process.

If your original cluster uses a custom 5.6-compatible cluster parameter group, create a corresponding 5.7-compatible cluster parameter group. You associate that parameter group with the cluster as part of the upgrade process.

Similarly, create any corresponding 5.7-compatible DB parameter group. You associate that parameter group with all the DB instances in the cluster as part of the upgrade process.

**Important**

If you specify any custom parameter group during the upgrade process, you must manually reboot the cluster after the upgrade finishes. Doing so makes the cluster begin using your custom parameter settings.

## Changes to cluster properties between Aurora MySQL version 1 and 2

For MySQL 5.6-compatible clusters, the value that you use for the `engine` parameter in AWS CLI commands or RDS API operations is `aurora`. For MySQL 5.7-compatible or MySQL 8.0-compatible

clusters, the corresponding value is `aurora-mysql`. When you upgrade from Aurora MySQL version 1 to version 2 or version 3, make sure to change any applications or scripts you use to set up or manage Aurora MySQL clusters and DB instances.

Also, change your code that manipulates parameter groups to account for the fact that the default parameter group names are different for MySQL 5.6-, 5.7-, and 8.0-compatible clusters. The default parameter group name for Aurora MySQL version 1 clusters is `default.aurora5.6`. The corresponding parameter group names for Aurora MySQL version 2 and 3 clusters are `default.aurora-mysql5.7` and `default.aurora-mysql8.0`.

For example, you might have code like the following that applies to your cluster before an upgrade.

```
# Add a new DB instance to a MySQL 5.6-compatible cluster.  
aws rds create-db-instance --db-instance-identifier instance-2020-04-28-6889 --db-cluster-  
identifier cluster-2020-04-28-2690 \  
--db-instance-class db.t2.small --engine aurora --region us-east-1  
  
# Find the Aurora MySQL v1.x versions available for minor version upgrades and patching.  
aws rds describe-orderable-db-instance-options --engine aurora --region us-east-1 \  
--query 'OrderableDBInstanceOptions[].[EngineVersion:EngineVersion]' --output text  
  
# Check the default parameter values for MySQL 5.6-compatible clusters.  
aws rds describe-db-parameters --db-parameter-group-name default.aurora5.6 --region us-  
east-1
```

After upgrading the major version of the cluster, modify that code as follows.

```
# Add a new DB instance to a MySQL 5.7-compatible cluster.  
aws rds create-db-instance --db-instance-identifier instance-2020-04-28-3333 --db-cluster-  
identifier cluster-2020-04-28-2690 \  
--db-instance-class db.t2.small --engine aurora-mysql --region us-east-1  
  
# Find the Aurora MySQL v2.x versions available for minor version upgrades and patching.  
aws rds describe-orderable-db-instance-options --engine aurora-mysql --region us-east-1 \  
--query 'OrderableDBInstanceOptions[].[EngineVersion:EngineVersion]' --output text  
  
# Check the default parameter values for MySQL 5.7-compatible clusters.  
aws rds describe-db-parameters --db-parameter-group-name default.aurora-mysql5.7 --region  
us-east-1
```

## In-place major upgrades for global databases

For an Aurora global database, you upgrade the global database cluster. Aurora automatically upgrades all of the clusters at the same time and makes sure that they all run the same engine version. This requirement is because any changes to system tables, data file formats, and so on, are automatically replicated to all the secondary clusters.

Follow the instructions in [How the Aurora MySQL in-place major version upgrade works \(p. 1005\)](#). When you specify what to upgrade, make sure to choose the global database cluster instead of one of the clusters it contains.

If you use the AWS Management Console, choose the item with the role **Global database**.

DB identifier	Role	En
global-cluster	Global database	Au
cluster1	Primary cluster	Au
dbinstance-1	Writer instance	Au
cluster-2	Secondary cluster	Au
dbinstance-2	Reader instance	Au

If you use the AWS CLI or RDS API, start the upgrade process by calling the [modify-global-cluster](#) command or [ModifyGlobalCluster](#) operation instead of `modify-db-cluster` or `ModifyDBCluster`.

**Note**

You can't specify a custom parameter group for the global database cluster while you're performing a major version upgrade of that Aurora global database. Create your custom parameter groups in each Region of the global cluster and then apply them manually to the Regional clusters after the upgrade.

## After the upgrade

If the cluster you upgraded had the backtrack feature enabled, you can't backtrack the upgraded cluster to a time that's before the upgrade.

## Troubleshooting for Aurora MySQL in-place upgrade

Use the following tips to help troubleshoot problems with Aurora MySQL in-place upgrades. These tips don't apply to Aurora Serverless DB clusters.

Reason for in-place upgrade being canceled or slow	Effect	Solution to allow in-place upgrade to complete within maintenance window
Cluster has XA transactions in the prepared state	Aurora cancels the upgrade.	Commit or roll back all prepared XA transactions.
Cluster is processing any data definition language (DDL) statements	Aurora cancels the upgrade.	Consider waiting and performing the upgrade after all DDL statements are finished.
Cluster has uncommitted changes for many rows	Upgrade might take a long time.	The upgrade process rolls back the uncommitted changes. The indicator for this condition is the value of <code>TRX_ROWS_MODIFIED</code> in the <code>INFORMATION_SCHEMA.INNODB_TRX</code> table.  Consider performing the upgrade only after all large transactions are committed or rolled back.
Cluster has high number of undo records	Upgrade might take a long time.	Even if the uncommitted transactions don't affect a large number of rows, they might involve a large volume of data. For example, you

Reason for in-place upgrade being canceled or slow	Effect	Solution to allow in-place upgrade to complete within maintenance window
		<p>might be inserting large BLOBs. Aurora doesn't automatically detect or generate an event for this kind of transaction activity. The indicator for this condition is the history list length. The upgrade process rolls back the uncommitted changes.</p> <p>Consider performing the upgrade only after the history list length is smaller.</p>
Cluster is in the process of committing a large binary log transaction	Upgrade might take a long time.	<p>The upgrade process waits until the binary log changes are applied. More transactions or DDL statements could start during this period, further slowing down the upgrade process.</p> <p>Schedule the upgrade process when the cluster isn't busy with generating binary log replication changes. Aurora doesn't automatically detect or generate an event for this condition.</p>

You can use the following steps to perform your own checks for some of the conditions in the preceding table. That way, you can schedule the upgrade at a time when you know the database is in a state where the upgrade can complete successfully and quickly.

- You can check for open XA transactions by executing the `XA RECOVER` statement. You can then commit or roll back the XA transactions before starting the upgrade.
- You can check for DDL statements by executing a `SHOW PROCESSLIST` statement and looking for `CREATE`, `DROP`, `ALTER`, `RENAME`, and `TRUNCATE` statements in the output. Allow all DDL statements to finish before starting the upgrade.
- You can check the total number of uncommitted rows by querying the `INFORMATION_SCHEMA.INNODB_TRX` table. The table contains one row for each transaction. The `TRX_ROWS_MODIFIED` column contains the number of rows modified or inserted by the transaction.
- You can check the length of the InnoDB history list by executing the `SHOW ENGINE INNODB STATUS` SQL statement and looking for the `History list length` in the output. You can also check the value directly by running the following query:

```
SELECT count FROM information_schema.innodb_metrics WHERE name = 'trx_rseg_history_len';
```

The length of the history list corresponds to the amount of undo information stored by the database to implement multi-version concurrency control (MVCC).

## Aurora MySQL in-place upgrade tutorial

The following Linux examples show how you might perform the general steps of the in-place upgrade procedure using the AWS CLI.

This first example creates an Aurora DB cluster that's running a 1.x version of Aurora MySQL. The cluster includes a writer DB instance and a reader DB instance. The `wait db-instance-available` command pauses until the writer DB instance is available. That's the point when the cluster is ready to be upgraded.

```
$ aws rds create-db-cluster --db-cluster-identifier cluster-56-2020-11-17-3824 --engine aurora \
--db-cluster-version 5.6.mysql_aurora.1.22.3
```

```

...
$ aws rds create-db-instance --db-instance-identifier instance-2020-11-17-7832 \
--db-cluster-identifier cluster-56-2020-11-17-3824 --db-instance-class db.t2.medium --
engine aurora
...
$ aws rds wait db-instance-available --db-instance-identifier instance-2020-11-17-7832 --
region us-east-1

```

The Aurora MySQL 2.x versions that you can upgrade the cluster to depend on the 1.x version that the cluster is currently running and on the AWS Region where the cluster is located. The first command, with `--output text`, just shows the available target version. The second command shows the full JSON output of the response. In that detailed response, you can see details such as the `aurora-mysql` value you use for the engine parameter, and the fact that upgrading to 2.07.3 represents a major version upgrade.

```

$ aws rds describe-db-clusters --db-cluster-identifier cluster-56-2020-11-17-9355 \
--query '*[].[EngineVersion:EngineVersion]' --output text
5.6.mysql_aurora.1.22.3

$ aws rds describe-db-engine-versions --engine aurora --engine-version
5.6.mysql_aurora.1.22.3 \
--query '*[].[ValidUpgradeTarget]'
[
    [
        [
            {
                "Engine": "aurora-mysql",
                "EngineVersion": "5.7.mysql_aurora.2.07.3",
                "Description": "Aurora (MySQL 5.7) 2.07.3",
                "AutoUpgrade": false,
                "IsMajorVersionUpgrade": true
            }
        ]
    ]
]

```

This example shows how if you enter a target version number that isn't a valid upgrade target for the cluster, Aurora won't perform the upgrade. Aurora also won't perform a major version upgrade unless you include the `--allow-major-version-upgrade` parameter. That way, you can't accidentally perform an upgrade that has the potential to require extensive testing and changes to your application code.

```

$ aws rds modify-db-cluster --db-cluster-identifier cluster-56-2020-11-17-9355 \
--engine-version 5.7.mysql_aurora.2.04.9 --region us-east-1 --apply-immediately
An error occurred (InvalidParameterCombination) when calling the ModifyDBCluster
operation: Cannot find upgrade target from 5.6.mysql_aurora.1.22.3 with requested version
5.7.mysql_aurora.2.04.9.

$ aws rds modify-db-cluster --db-cluster-identifier cluster-56-2020-11-17-9355 \
--engine-version 5.7.mysql_aurora.2.09.0 --region us-east-1 --apply-immediately
An error occurred (InvalidParameterCombination) when calling the ModifyDBCluster operation:
The AllowMajorVersionUpgrade flag must be present when upgrading to a new major version.

$ aws rds modify-db-cluster --db-cluster-identifier cluster-56-2020-11-17-9355 \
--engine-version 5.7.mysql_aurora.2.09.0 --region us-east-1 --apply-immediately --allow-
major-version-upgrade
{
    "DBClusterIdentifier": "cluster-56-2020-11-17-9355",
    "Status": "available",
    "Engine": "aurora",
    "EngineVersion": "5.6.mysql_aurora.1.22.3"
}

```

It takes a few moments for the status of the cluster and associated DB instances to change to upgrading. The version numbers for the cluster and DB instances only change when the upgrade is finished. Again, you can use the `wait db-instance-available` command for the writer DB instance to wait until the upgrade is finished before proceeding.

```
$ aws rds describe-db-clusters --db-cluster-identifier cluster-56-2020-11-17-9355 \
--query '*[].[Status,EngineVersion]' --output text
upgrading 5.6.mysql_aurora.1.22.3

$ aws rds describe-db-instances --db-instance-identifier instance-2020-11-17-5158 \
--query '*[.]'
{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceState:DBInstanceState} | [0]{
{
    "DBInstanceIdentifier": "instance-2020-11-17-5158",
    "DBInstanceState": "upgrading"
}

$ aws rds wait db-instance-available --db-instance-identifier instance-2020-11-17-5158
```

At this point, the version number for the cluster matches the one that was specified for the upgrade.

```
$ aws rds describe-db-clusters --region us-east-1 --db-cluster-identifier
cluster-56-2020-11-17-9355 \
--query '*[].[EngineVersion]' --output text
5.7.mysql_aurora.2.09.0
```

The preceding example did an immediate upgrade by specifying the `--apply-immediately` parameter. To let the upgrade happen at a convenient time when the cluster isn't expected to be busy, you can specify the `--no-apply-immediately` parameter. Doing so makes the upgrade start during the next maintenance window for the cluster. The maintenance window defines the period during which maintenance operations can start. A long-running operation might not finish during the maintenance window. Thus, you don't need to define a larger maintenance window even if you expect that the upgrade might take a long time.

The following example upgrades a cluster that's initially running Aurora MySQL version 1.22.2. In the `describe-db-engine-versions` output, the `False` and `True` values represent the `IsMajorVersionUpgrade` property. From version 1.22.2, you can upgrade to some other 1.\* versions. Those upgrades aren't considered major version upgrades and so don't require an in-place upgrade. In-place upgrade is only available for upgrades to the 2.07 and 2.09 versions that are shown in the list.

```
$ aws rds describe-db-clusters --region us-east-1 --db-cluster-identifier
cluster-56-2020-11-17-3824 \
--query '*[].[EngineVersion:EngineVersion]' --output text
5.6.mysql_aurora.1.22.2

$ aws rds describe-db-engine-versions --engine aurora --engine-version
5.6.mysql_aurora.1.22.2 \
--query '*[].[ValidUpgradeTarget]|[0][0]|[*].[EngineVersion,IsMajorVersionUpgrade]' --
output text
5.6.mysql_aurora.1.22.3 False
5.6.mysql_aurora.1.23.0 False
5.6.mysql_aurora.1.23.1 False
5.7.mysql_aurora.2.07.1 True
5.7.mysql_aurora.2.07.1 True
5.7.mysql_aurora.2.07.2 True
5.7.mysql_aurora.2.07.3 True
5.7.mysql_aurora.2.09.1 True

$ aws rds modify-db-cluster --db-cluster-identifier cluster-56-2020-11-17-9355 \
--engine-version 5.7.mysql_aurora.2.09.0 --region us-east-1 --no-apply-immediately --allow-major-version-upgrade
```

...

When a cluster is created without a specified maintenance window, Aurora picks a random day of the week. In this case, the `modify-db-cluster` command is submitted on a Monday. Thus, we change the maintenance window to be Tuesday morning. All times are represented in the UTC time zone. The `tue:10:00-tue:10:30` window corresponds to 2-2:30 AM Pacific time. The change in the maintenance window takes effect immediately.

```
$ aws rds describe-db-clusters --db-cluster-identifier cluster-56-2020-11-17-9355 --region us-east-1 --query '*[].[PreferredMaintenanceWindow]'
[
  [
    "sat:08:20-sat:08:50"
  ]
]

$ aws rds modify-db-cluster --db-cluster-identifier cluster-56-2020-11-17-3824 --preferred-maintenance-window tue:10:00-tue:10:30"
$ aws rds describe-db-clusters --db-cluster-identifier cluster-56-2020-11-17-3824 --region us-east-1 --query '*[].[PreferredMaintenanceWindow]'
[
  [
    "tue:10:00-tue:10:30"
  ]
]
```

```
$ aws rds create-db-cluster --engine aurora --db-cluster-identifier
cluster-56-2020-11-17-9355 \
--region us-east-1 --master-username my_username --master-user-password my_password
{
  "DBClusterIdentifier": "cluster-56-2020-11-17-9355",
  "DBClusterArn": "arn:aws:rds:us-east-1:123456789012:cluster:cluster-56-2020-11-17-9355",
  "Engine": "aurora",
  "EngineVersion": "5.6.mysql_aurora.1.22.2",
  "Status": "creating",
  "Endpoint": "cluster-56-2020-11-17-9355.cluster-ccfbt21ixr91.us-east-1-
integ.rds.amazonaws.com",
  "ReaderEndpoint": "cluster-56-2020-11-17-9355.cluster-ro-ccfbt21ixr91.us-east-1-
integ.rds.amazonaws.com"
}

$ aws rds create-db-instance --db-instance-identifier instance-2020-11-17-5158 \
--db-cluster-identifier cluster-56-2020-11-17-9355 --db-instance-class db.r5.large --
region us-east-1 --engine aurora
{
  "DBInstanceIdentifier": "instance-2020-11-17-5158",
  "DBClusterIdentifier": "cluster-56-2020-11-17-9355",
  "DBInstanceClass": "db.r5.large",
  "DBInstanceStatus": "creating"
}

$ aws rds wait db-instance-available --db-instance-identifier instance-2020-11-17-5158 --
region us-east-1
```

The following example shows how to get a report of the events generated by the upgrade. The `--duration` argument represents the number of minutes to retrieve the event information. This argument is needed because by default, `describe-events` only returns events from the last hour.

```
$ aws rds describe-events --source-type db-cluster --source-identifier
cluster-56-2020-11-17-3824 --duration 20160
{
  "Events": [
```

```

## Alternative blue-green upgrade technique

For situations where the top priority is to perform an immediate switchover from the old cluster to an upgraded one, you can use a multistep process that runs the old and new clusters side-by-side. In this case, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see this blog post: [Performing major version upgrades for Amazon Aurora MySQL with minimum downtime](#).

# Working with Amazon Aurora PostgreSQL

Amazon Aurora PostgreSQL is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed, reliability, and manageability of Amazon Aurora with the simplicity and cost-effectiveness of open-source databases. Aurora PostgreSQL is a drop-in replacement for PostgreSQL and makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. To learn more about Aurora in general, see [What is Amazon Aurora? \(p. 1\)](#).

In addition to the benefits of Aurora, Aurora PostgreSQL offers a convenient migration pathway from Amazon RDS into Aurora, with push-button migration tools that convert your existing RDS for PostgreSQL applications to Aurora PostgreSQL. Routine database tasks such as provisioning, patching, backup, recovery, failure detection, and repair are also easy to manage with Aurora PostgreSQL.

Aurora PostgreSQL can work with many industry standards. For example, you can use Aurora PostgreSQL databases to build HIPAA-compliant applications and to store healthcare related information, including protected health information (PHI), under a completed Business Associate Agreement (BAA) with AWS.

Aurora PostgreSQL is FedRAMP HIGH eligible. For details about AWS and compliance efforts, see [AWS services in scope by compliance program](#).

## Security with Amazon Aurora PostgreSQL

For a general overview of Aurora security, see [Security in Amazon Aurora \(p. 1634\)](#). You can manage security for Amazon Aurora PostgreSQL at a few different levels:

- To control who can perform Amazon RDS management actions on Aurora PostgreSQL DB clusters and DB instances, use AWS Identity and Access Management (IAM). IAM handles the authentication of user identity before the user can access the service. It also handles authorization, that is, whether the user is allowed to do what they're trying to do. IAM database authentication is an additional authentication method that you can choose when you create your Aurora PostgreSQL DB cluster. For more information, see [Identity and access management for Amazon Aurora \(p. 1653\)](#).

If you do use IAM with your Aurora PostgreSQL DB cluster, sign in to the AWS Management Console with your IAM credentials first, before opening the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

- Make sure to create Aurora DB clusters in a virtual public cloud (VPC) based on the Amazon VPC service. To control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance for Aurora DB clusters in a VPC, use a VPC security group. You can make these endpoint and port connections by using Secure Sockets Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see [Amazon VPC VPCs and Amazon Aurora \(p. 1729\)](#).

The supported VPC tenancy depends on the DB instance class used by your Aurora PostgreSQL DB clusters. With default VPC tenancy, the VPC runs on shared hardware. With dedicated VPC tenancy, the VPC runs on a dedicated hardware instance. The burstable performance DB instance classes support default VPC tenancy only. The burstable performance DB instance classes include the db.t3 and db.t4g DB instance classes. All other Aurora PostgreSQL DB instance classes support both default and dedicated VPC tenancy.

For more information about instance classes, see [Aurora DB instance classes \(p. 56\)](#). For more information about default and dedicated VPC tenancy, see [Dedicated instances](#) in the [Amazon Elastic Compute Cloud User Guide](#).

- To grant permissions to the PostgreSQL databases running on your Amazon Aurora DB cluster, you can take the same general approach as with stand-alone instances of PostgreSQL. Commands such as `CREATE ROLE`, `ALTER ROLE`, `GRANT`, and `REVOKE` work just as they do in on-premises databases, as does directly modifying databases, schemas, and tables.

PostgreSQL manages privileges by using *roles*. The `rds_superuser` role is the most privileged role on an Aurora PostgreSQL DB cluster. This role is created automatically, and it's granted to the user that creates the DB cluster (the master user account, `postgres` by default). To learn more, see [Understanding PostgreSQL roles and permissions \(p. 1019\)](#).

Aurora PostgreSQL 14.3 and higher releases support the Salted Challenge Response Authentication Mechanism (SCRAM) for passwords as an alternative to message digest (MD5). We recommend that you use SCRAM because it's more secure than MD5. For more information, including how to migrate database user passwords from MD5 to SCRAM, see [Using SCRAM for PostgreSQL password encryption \(p. 1024\)](#).

## Understanding PostgreSQL roles and permissions

When you create an Aurora PostgreSQL DB cluster using the AWS Management Console, an administrator account is created at the same time. By default, its name is `postgres`, as shown in the following screenshot:

The screenshot shows the 'Credentials Settings' step of the 'Create DB Cluster' wizard. It includes fields for 'Master username' (set to 'postgres'), 'Master password', and 'Confirm password', each with a masked input field.

You can choose another name rather than accept the default (`postgres`). If you do, the name you choose must start with a letter and be between 1 and 16 alphanumeric characters. For simplicity's sake, we refer to this main user account by its default value (`postgres`) throughout this guide.

If you use the `create-db-cluster` AWS CLI rather than the AWS Management Console, you create the user name by passing it with the `master-username` parameter. For more information, see [Create an Aurora PostgreSQL DB cluster \(p. 101\)](#).

Whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API, and whether you use the default `postgres` name or choose a different name, this first database user account is a member of the `rds_superuser` group and has `rds_superuser` privileges.

## Understanding the `rds_superuser` role

In PostgreSQL, a *role* can define a user, a group, or a set of specific permissions granted to a group or user for various objects in the database. PostgreSQL commands to `CREATE USER` and `CREATE GROUP` have been replaced by the more general, `CREATE ROLE` with specific properties to distinguish database users. A database user can be thought of as a role with the `LOGIN` privilege.

#### Note

The `CREATE USER` and `CREATE GROUP` commands can still be used. For more information, see [Database Roles](#) in the PostgreSQL documentation.

The `postgres` user is the most highly privileged database user on your Aurora PostgreSQL DB cluster. It has the characteristics defined by the following `CREATE ROLE` statement.

```
CREATE ROLE postgres WITH LOGIN NOSUPERUSER INHERIT CREATEDB CREATEROLE NOREPLICATION VALID UNTIL 'infinity'
```

The properties `NOSUPERUSER`, `NOREPLICATION`, `INHERIT`, and `VALID UNTIL 'infinity'` are the default options for `CREATE ROLE`, unless otherwise specified.

By default, `postgres` has privileges granted to the `rds_superuser` role. The `rds_superuser` role allows the `postgres` user to do the following:

- Add extensions that are available for use with Aurora PostgreSQL. For more information, see [Working with extensions and foreign data wrappers \(p. 1318\)](#).
- Create roles for users and grant privileges to users. For more information, see [CREATE ROLE](#) and [GRANT](#) in the PostgreSQL documentation.
- Create databases. For more information, see [CREATE DATABASE](#) in the PostgreSQL documentation.
- Grant `rds_superuser` privileges to user roles that don't have these privileges, and revoke privileges as needed. We recommend that you grant this role only to those users who perform superuser tasks. In other words, you can grant this role to database administrators (DBAs) or system administrators.
- Grant (and revoke) the `rds_replication` role to database users that don't have the `rds_superuser` role.
- Grant (and revoke) the `rds_password` role to database users that don't have the `rds_superuser` role.
- Obtain status information about all database connections by using the `pg_stat_activity` view. When needed, `rds_superuser` can stop any connections by using `pg_terminate_backend` or `pg_cancel_backend`.

In the `CREATE ROLE postgres...` statement, you can see that the `postgres` user role specifically disallows PostgreSQL superuser permissions. Aurora PostgreSQL is a managed service, so you can't access the host OS, and you can't connect using the PostgreSQL superuser account. Many of the tasks that require superuser access on a stand-alone PostgreSQL are managed automatically by Aurora.

For more information about granting privileges, see [GRANT](#) in the PostgreSQL documentation.

The `rds_superuser` role is one of several *predefined* roles in an Aurora PostgreSQL DB cluster.

**Note**

In PostgreSQL 13 and earlier releases, *predefined* roles are known as *default* roles.

In the following list, you find some of the other predefined roles that are created automatically for a new Aurora PostgreSQL DB cluster. Predefined roles and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined roles. Attempting to do so results in an error.

- **rds\_password** – A role that can change passwords and set up password constraints for database users. The `rds_superuser` role is granted this role by default, and can grant the role to database users. For more information, see [Controlling user access to the PostgreSQL database \(p. 1022\)](#).
- **rdsadmin** – A role that's created to handle many of the management tasks that the administrator with `superuser` privileges would perform on a standalone PostgreSQL database. This role is used internally by Aurora PostgreSQL for many management tasks.

To see all predefined roles, you can connect to the primary instance of your Aurora PostgreSQL DB cluster and use the `\du` metacommand. The output looks as follows:

List of roles		
Role name	Attributes	Member of
postgres	Create role, Create DB   Password valid until infinity	+  {rds_superuser}
rds_superuser	Cannot login	{pg_monitor,pg_signal_backend, +  rds_replication,rds_password}
...		

In the output, you can see that `rds_superuser` isn't a database user role (it can't login), but it has the privileges of many other roles. You can also see that database user `postgres` is a member of the `rds_superuser` role. As mentioned previously, `postgres` is the default value in the Amazon RDS console's [Create database](#) page. If you chose another name, that name is shown in the list of roles instead.

## Controlling user access to the PostgreSQL database

New databases in PostgreSQL are always created with a default set of privileges in the database's `public` schema that allow all database users and roles to create objects. These privileges allow database users to connect to the database, for example, and create temporary tables while connected.

To better control user access to the databases instances that you create on your Aurora PostgreSQL DB cluster primary node , we recommend that you revoke these default `public` privileges. After doing so, you then grant specific privileges for database users on a more granular basis, as shown in the following procedure.

### To set up roles and privileges for a new database instance

Suppose you're setting up a database on a newly created Aurora PostgreSQL DB cluster for use by several researchers, all of whom need read-write access to the database.

1. Use `psql` (or `pgAdmin`) to connect to the primary DB instance on your Aurora PostgreSQL DB cluster:

```
psql --host=your-cluster-instance-1.666666666666.aws-region.rds.amazonaws.com --  
port=5432 --username=postgres --password
```

When prompted, enter your password. The `psql` client connects and displays the default administrative connection database, `postgres=>`, as the prompt.

2. To prevent database users from creating objects in the `public` schema, do the following:

```
postgres=> REVOKE CREATE ON SCHEMA public FROM PUBLIC;  
REVOKE
```

3. Next, you create a new database instance:

```
postgres=> CREATE DATABASE lab_db;  
CREATE DATABASE
```

4. Revoke all privileges from the `PUBLIC` schema on this new database.

```
postgres=> REVOKE ALL ON DATABASE lab_db FROM public;  
REVOKE
```

5. Create a role for database users.

```
postgres=> CREATE ROLE lab_tech;  
CREATE ROLE
```

6. Give database users that have this role the ability to connect to the database.

```
postgres=> GRANT CONNECT ON DATABASE lab_db TO lab_tech;  
GRANT
```

7. Grant all users with the `lab_tech` role all privileges on this database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_db TO lab_tech;  
GRANT
```

8. Create database users, as follows:

```
postgres=> CREATE ROLE lab_user1 LOGIN PASSWORD 'change_me';
```

```
CREATE ROLE
postgres=> CREATE ROLE lab_user2 LOGIN PASSWORD 'change_me';
CREATE ROLE
```

9. Grant these two users the privileges associated with the lab\_tech role:

```
postgres=> GRANT lab_tech TO lab_user1;
GRANT ROLE
postgres=> GRANT lab_tech TO lab_user2;
GRANT ROLE
```

At this point, lab\_user1 and lab\_user2 can connect to the lab\_db database. This example doesn't follow best practices for enterprise usage, which might include creating multiple database instances, different schemas, and granting limited permissions. For more complete information and additional scenarios, see [Managing PostgreSQL Users and Roles](#).

For more information about privileges in PostgreSQL databases, see the [GRANT command](#) in the PostgreSQL documentation.

## Delegating and controlling user password management

As a DBA, you might want to delegate the management of user passwords. Or, you might want to prevent database users from changing their passwords or reconfiguring password constraints, such as password lifetime. To ensure that only the database users that you choose can change password settings, you can turn on the restricted password management feature. When you activate this feature, only those database users that have been granted the rds\_password role can manage passwords.

### Note

To use restricted password management, your Aurora PostgreSQL DB cluster must be running Amazon Aurora PostgreSQL 10.6 or higher.

By default, this feature is off, as shown in the following:

```
postgres=> SHOW rds.restrict_password_commands;
rds.restrict_password_commands
-----
off
(1 row)
```

To turn on this feature, you use a custom parameter group and change the setting for rds.restrict\_password\_commands to 1. Be sure to reboot your Aurora PostgreSQL's primary DB instance so that the setting takes effect.

With this feature active, rds\_password privileges are needed for the following SQL commands:

```
CREATE ROLE myrole WITH PASSWORD 'mypassword';
CREATE ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword';
ALTER ROLE myrole VALID UNTIL '2023-01-01';
ALTER ROLE myrole RENAME TO myrole2;
```

Renaming a role (ALTER ROLE myrole RENAME TO newname) is also restricted if the password uses the MD5 hashing algorithm.

With this feature active, attempting any of these SQL commands without the rds\_password role permissions generates the following error:

```
ERROR: must be a member of rds_password to alter passwords
```

We recommend that you grant the `rds_password` to only a few roles that you use solely for password management. If you grant `rds_password` privileges to database users that don't have `rds_superuser` privileges, you need to also grant them the `CREATEROLE` attribute.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. If you use your own client-side utility for password related changes, the utility needs to be a member of `rds_password` and have `CREATE ROLE` privileges.

## Using SCRAM for PostgreSQL password encryption

The *Salted Challenge Response Authentication Mechanism (SCRAM)* is an alternative to PostgreSQL's default message digest (MD5) algorithm for encrypting passwords. The SCRAM authentication mechanism is considered more secure than MD5. To learn more about these two different approaches to securing passwords, see [Password Authentication](#) in the PostgreSQL documentation.

We recommend that you use SCRAM rather than MD5 as the password encryption scheme for your Aurora PostgreSQL DB cluster. As of the Aurora PostgreSQL 14 release, SCRAM is supported in all available Aurora PostgreSQL versions, including versions 10, 11, 12, 13, and 14. It's a cryptographic challenge-response mechanism that uses the `scram-sha-256` algorithm for password authentication and encryption.

You might need to update libraries for your client applications to support SCRAM. For example, JDBC versions before 42.2.0 don't support SCRAM. For more information, see [PostgreSQL JDBC Driver](#) in the PostgreSQL JDBC Driver documentation. For a list of other PostgreSQL drivers and SCRAM support, see [List of drivers](#) in the PostgreSQL documentation.

### Note

Aurora PostgreSQL version 14 and higher support `scram-sha-256` for password encryption by default for new DB clusters. That is, the default DB cluster parameter group (`default.aurora-postgresql14`) has its `password_encryption` value set to `scram-sha-256`.

## Setting up Aurora PostgreSQL DB cluster to require SCRAM

For Aurora PostgreSQL 14.3 and higher versions, you can require the Aurora PostgreSQL DB cluster to accept only passwords that use the `scram-sha-256` algorithm.

### Note

Currently, this capability isn't supported with RDS Proxy.

Before making changes to your system, be sure you understand the complete process, as follows:

- Get information about all roles and password encryption for all database users.
- Double-check the parameter settings for your Aurora PostgreSQL DB cluster for the parameters that control password encryption.
- If your Aurora PostgreSQL DB cluster uses a default parameter group, you need to create a custom DB cluster parameter group and apply it to your Aurora PostgreSQL DB cluster so that you can modify parameters when needed. If your Aurora PostgreSQL DB cluster uses a custom parameter group, you can modify the necessary parameters later in the process, as needed.
- Change the `password_encryption` parameter to `scram-sha-256`.
- Notify all database users that they need to update their passwords. Do the same for your `postgres` account. The new passwords are encrypted and stored using the `scram-sha-256` algorithm.
- Verify that all passwords are encrypted using as the type of encryption.

- If all passwords use scram-sha-256, you can change the `rds.accepted_password_auth_method` parameter from `md5+scram` to `scram-sha-256`.

**Warning**

After you change `rds.accepted_password_auth_method` to `scram-sha-256` alone, any users (roles) with `md5`-encrypted passwords can't connect.

## Getting ready to require SCRAM for your Aurora PostgreSQL DB cluster

Before making any changes to your Aurora PostgreSQL DB cluster, check all existing database user accounts. Also, check the type of encryption used for passwords. You can do these tasks by using the `rds_tools` extension. This extension is supported on Aurora PostgreSQL 13.1 and higher releases.

### To get a list of database users (roles) and password encryption methods

1. Use `psql` to connect to the primary instance of your Aurora PostgreSQL DB cluster , as shown in the following.

```
psql --host=cluster-name-instance-1.111122223333.aws-region.rds.amazonaws.com --  
port=5432 --username=postgres --password
```

2. Install the `rds_tools` extension.

```
postgres=> CREATE EXTENSION rds_tools;  
CREATE EXTENSION
```

3. Get a listing of roles and encryption.

```
postgres=> SELECT * FROM  
rds_tools.role_password_encryption_type();
```

You see output similar to the following.

rolname	encryption_type
pg_monitor	
pg_read_all_settings	
pg_read_all_stats	
pg_stat_scan_tables	
pg_signal_backend	
lab_tester	md5
user_465	md5
postgres	md5
(8 rows)	

## Creating a custom DB cluster parameter group

**Note**

If your Aurora PostgreSQL DB cluster already uses a custom parameter group, you don't need to create a new one.

For an overview of parameter groups for Aurora, see [Creating a DB cluster parameter group \(p. 219\)](#).

The password encryption type used for passwords is set in one parameter, `password_encryption`. The encryption that the Aurora PostgreSQL DB cluster allows is set in another parameter, `rds.accepted_password_auth_method`. Changing either of these from the default values requires that you create a custom DB cluster parameter group and apply it to your cluster.

You can also use the AWS Management Console or the RDS API to create a custom DB cluster parameter group . For more information, see [Creating a DB cluster parameter group \(p. 219\)](#).

You can now associate the custom parameter group with your DB instance.

### To create a custom DB cluster parameter group

1. Use the `create-db-cluster-parameter-group` CLI command to create the custom parameter group for the cluster. The following example uses `aurora-postgresql13` as the source for this custom parameter group.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name 'docs-lab-scram-passwords' \
    --db-parameter-group-family aurora-postgresql13 --description 'Custom DB cluster parameter group for SCRAM'
```

For Windows:

```
aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name "docs-lab-scram-passwords" ^
    --db-parameter-group-family aurora-postgresql13 --description "Custom DB cluster parameter group for SCRAM"
```

You can now associate the custom parameter group with your cluster.

2. Use the `modify-db-cluster` CLI command to apply this custom parameter group to your Aurora PostgreSQL DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster --db-cluster-identifier 'your-instance-name' \
    ----db-cluster-parameter-group-name "docs-lab-scram-passwords"
```

For Windows:

```
aws rds modify-db-cluster --db-cluster-identifier "your-instance-name" ^
    ----db-cluster-parameter-group-name "docs-lab-scram-passwords"
```

To resynchronize your Aurora PostgreSQL DB cluster with your custom DB cluster parameter group, reboot the primary and all other instances of the cluster.

### Configuring password encryption to use SCRAM

The password encryption mechanism used by an Aurora PostgreSQL DB cluster is set in the DB cluster parameter group in the `password_encryption` parameter. Allowed values are `unset`, `md5`, or `scram-sha-256`. The default value depends on the Aurora PostgreSQL version, as follows:

- Aurora PostgreSQL 14 – Default is `scram-sha-256`
- Aurora PostgreSQL 13 – Default is `md5`

With a custom DB cluster parameter group attached to your Aurora PostgreSQL DB cluster, you can modify values for the `password_encryption` parameter.

<input type="checkbox"/>	Name	Values ▾	Allowed values	Modifiable ▾	Source ▾	Apply type ▾
<input type="checkbox"/>	password_encryption	scram-sha-256	md5, scram-sha-256	true	system	dynamic
<input type="checkbox"/>	rds.accepted_password_auth_method	md5+scram	md5+scram, scram	true	system	dynamic

### To change password encryption setting to scram-sha-256

- Change the value of the password encryption to scram-sha-256, as shown following. The change can be applied immediately because the parameter is dynamic, so a restart isn't required for the change to take effect.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group --db-parameter-group-name \
  'docs-lab-scram-passwords' --parameters
  'ParameterName=password_encryption,ParameterValue=scram-sha-256,ApplyMethod=immediate'
```

For Windows:

```
aws rds modify-db-parameter-group --db-parameter-group-name ^
  "docs-lab-scram-passwords" --parameters
  "ParameterName=password_encryption,ParameterValue=scram-sha-256,ApplyMethod=immediate"
```

### Migrating passwords for user roles to SCRAM

You can migrate passwords for user roles to SCRAM as described following.

#### To migrate database user (role) passwords from MD5 to SCRAM

- Log in as the administrator user (default user name, `postgres`) as shown following.

```
psql --host=cluster-name-instance-1.111122223333.aws-region.rds.amazonaws.com --
port=5432 --username=postgres --password
```

- Check the setting of the `password_encryption` parameter on your RDS for PostgreSQL DB instance by using the following command.

```
postgres=> SHOW password_encryption;
 password_encryption
-----
 md5
 (1 row)
```

- Change the value of this parameter to `scram-sha-256`. This is a dynamic parameter, so you don't need to reboot the instance after making this change. Check the value again to make sure that it's now set to `scram-sha-256`, as follows.

```
postgres=> SHOW password_encryption;
 password_encryption
-----
 scram-sha-256
 (1 row)
```

4. Notify all database users to change their passwords. Be sure to also change your own password for account `postgres` (the database user with `rds_superuser` privileges).

```
labdb=> ALTER ROLE postgres WITH LOGIN PASSWORD 'change_me';
ALTER ROLE
```

5. Repeat the process for all databases on your Aurora PostgreSQL DB cluster.

### Changing parameter to require SCRAM

This is the final step in the process. After you make the change in the following procedure, any user accounts (roles) that still use `md5` encryption for passwords can't log in to the Aurora PostgreSQL DB cluster.

The `rds.accepted_password_auth_method` specifies the encryption method that the Aurora PostgreSQL DB cluster accepts for a user password during the login process. The default value is `md5+scram`, meaning that either method is accepted. In the following image, you can find the default setting for this parameter.

<input type="checkbox"/>	Name	Values	Allowed values	Modifiable	Source	Apply type
<input type="checkbox"/>	password_encryption	scram-sha-256	md5, scram-sha-256	true	system	dynamic
<input type="checkbox"/>	rds.accepted_password_auth_method	md5+scram	md5+scram, <b>scram</b>	true	system	dynamic

The allowed values for this parameter are `md5+scram` or `scram` alone. Changing this parameter value to `scram` makes this a requirement.

### To change the parameter value to require SCRAM authentication for passwords

1. Verify that all database user passwords for all databases on your Aurora PostgreSQL DB cluster use `scram-sha-256` for password encryption. To do so, query `rds_tools` for the role (user) and encryption type, as follows.

```
postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
   rolname    | encryption_type
-----+-----
 pg_monitor  |
 pg_read_all_settings |
 pg_read_all_stats  |
 pg_stat_scan_tables |
 pg_signal_backend  |
 lab_tester     | scram-sha-256
 user_465      | scram-sha-256
 postgres       | scram-sha-256
( 3 rows )
```

2. Repeat the query across all DB instances in your Aurora PostgreSQL DB cluster.

If all passwords use `scram-sha-256`, you can proceed.

3. Change the value of the accepted password authentication to `scram-sha-256`, as follows.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name 'docs-lab-scram-passwords' \
```

```
--parameters
'ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediate'
```

For Windows:

```
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name "docs-lab-
scram-passwords" ^
--parameters
"ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediate"
```

## Securing Aurora PostgreSQL data with SSL/TLS

Amazon RDS supports Secure Socket Layer (SSL) and Transport Layer Security (TLS) encryption for Aurora PostgreSQL DB clusters. Using SSL/TLS, you can encrypt a connection between your applications and your Aurora PostgreSQL DB clusters. You can also force all connections to your Aurora PostgreSQL DB cluster to use SSL/TLS. Amazon Aurora PostgreSQL supports Transport Layer Security (TLS) versions 1.1 and 1.2. We recommend using TLS 1.2 for encrypted connections.

For general information about SSL/TLS support and PostgreSQL databases, see [SSL support](#) in the PostgreSQL documentation. For information about using an SSL/TLS connection over JDBC, see [Configuring the client](#) in the PostgreSQL documentation.

### Topics

- [Requiring an SSL/TLS connection to an Aurora PostgreSQL DB cluster \(p. 1030\)](#)
- [Determining the SSL/TLS connection status \(p. 1030\)](#)
- [Configuring cipher suites for connections to Aurora PostgreSQL DB clusters \(p. 1031\)](#)

SSL/TLS support is available in all AWS Regions for Aurora PostgreSQL. Amazon RDS creates an SSL/TLS certificate for your Aurora PostgreSQL DB cluster when the DB cluster is created. If you enable SSL/TLS certificate verification, then the SSL/TLS certificate includes the DB cluster endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

### To connect to an Aurora PostgreSQL DB cluster over SSL/TLS

1. Download the certificate.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).

2. Import the certificate into your operating system.
3. Connect to your Aurora PostgreSQL DB cluster over SSL/TLS.

When you connect using SSL/TLS, your client can choose to verify the certificate chain or not. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

When a client, such as `psql` or JDBC, is configured with SSL/TLS support, the client first tries to connect to the database with SSL/TLS by default. If the client can't connect with SSL/TLS, it reverts to connecting without SSL/TLS. The default `sslmode` mode used is different between libpq-based clients (such as `psql`) and JDBC. The libpq-based clients default to `prefer`, where JDBC clients default to `verify-full`.

Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ssl-ca-cert.pem`.

The following is an example of using psql to connect to an Aurora PostgreSQL DB cluster.

```
$ psql -h testpg.cdhmuqifdpib.us-east-1.rds.amazonaws.com -p 5432 \
"dbname=testpg user=testuser sslrootcert=rds-ca-2015-root.pem sslmode=verify-full"
```

## Requiring an SSL/TLS connection to an Aurora PostgreSQL DB cluster

You can require that connections to your Aurora PostgreSQL DB cluster use SSL/TLS by using the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). You can set the `rds.force_ssl` parameter to 1 (on) to require SSL/TLS for connections to your DB cluster. Updating the `rds.force_ssl` parameter also sets the PostgreSQL `ssl` parameter to 1 (on) and modifies your DB cluster's `pg_hba.conf` file to support the new SSL/TLS configuration.

You can set the `rds.force_ssl` parameter value by updating the DB cluster parameter group for your DB cluster. If the DB cluster parameter group isn't the default one, and the `ssl` parameter is already set to 1 when you set `rds.force_ssl` to 1, you don't need to reboot your DB cluster. Otherwise, you must reboot your DB cluster for the change to take effect. For more information on parameter groups, see [Working with parameter groups \(p. 215\)](#).

When the `rds.force_ssl` parameter is set to 1 for a DB cluster, you see output similar to the following when you connect, indicating that SSL/TLS is now required:

```
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser
psql (9.3.12, server 9.4.4)
WARNING: psql major version 9.3, server major version 9.4.
Some psql features might not work.
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.

postgres=>
```

## Determining the SSL/TLS connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB cluster.

```
Password for user master:
psql (9.3.12)
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.

postgres=>
```

You can also load the `sslinfo` extension and then call the `ssl_is_used()` function to determine if SSL/TLS is being used. The function returns `t` if the connection is using SSL/TLS, otherwise it returns `f`.

```
postgres=> create extension sslinfo;
CREATE EXTENSION

postgres=> select ssl_is_used();
 ssl_is_used
-----
t
```

(1 row)

You can use the `select ssl_cipher()` command to determine the SSL/TLS cipher:

```
postgres=> select ssl_cipher();
ssl_cipher
-----
DHE-RSA-AES256-SHA
(1 row)
```

If you enable `set rds.force_ssl` and restart your DB cluster, non-SSL connections are refused with the following message:

```
$ export PGSSLMODE=disable
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser
psql: FATAL: no pg_hba.conf entry for host "host.ip", user "someuser", database "postgres",
      SSL off
$
```

For information about the `sslmode` option, see [Database connection control functions](#) in the PostgreSQL documentation.

## Configuring cipher suites for connections to Aurora PostgreSQL DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client SSL/TLS connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this helps prevent the use of insecure or deprecated ciphers.

Configurable cipher suites is supported in Aurora PostgreSQL versions 11.8 and higher.

To specify the list of permissible ciphers for encrypting connections, modify the `ssl_ciphers` cluster parameter. Set the `ssl_ciphers` parameter in a cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API. To set cluster parameters, see [Modifying parameters in a DB cluster parameter group \(p. 221\)](#).

Set the `ssl_ciphers` parameter to a string of comma-separated cipher values. The valid ciphers include the following:

- ECDHE-RSA-AES128-SHA
- ECDHE-RSA-AES128-SHA256
- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-RSA-AES256-SHA
- ECDHE-RSA-AES256-GCM-SHA384

You can also use the `describe-engine-default-cluster-parameters` CLI command to determine which cipher suites are currently supported for a specific parameter group family. The following example shows how to get the allowed values for the `ssl_cipher` cluster parameter for Aurora PostgreSQL 11.

```
aws rds describe-engine-default-cluster-parameters --db-parameter-group-family aurora-
postresql11
```

```
...some output truncated...
{
  "ParameterName": "ssl_ciphers",
  "Description": "Sets the list of allowed TLS ciphers to be used on secure connections.",
  "Source": "engine-default",
  "ApplyType": "dynamic",
  "DataType": "list",
  "AllowedValues": "ECDHE-RSA-AES256-GCM-SHA384,ECDHE-RSA-AES256-SHA384,AES256-SHA,AES128-SHA,DES-CBC3-SHA,ADH-DES-CBC3-SHA,EDH-RSA-DES-CBC3-SHA,EDH-DSS-DES-CBC3-SHA,ADH-AES256-SHA,DHE-RSA-AES256-SHA,DHE-DSS-AES256-SHA,ADH-AES128-SHA,DHE-RSA-AES128-SHA,DHE-DSS-AES128-SHA,HIGH",
  "IsModifiable": true,
  "MinimumEngineVersion": "11.8",
  "SupportedEngineModes": [
    "provisioned"
  ],
},
...some output truncated...
```

The `ssl_ciphers` parameter has no default string of cipher suites. For more information about ciphers, see the [ssl\\_ciphers](#) variable in the PostgreSQL documentation. For more information about cipher suite formats, see the [openssl-ciphers list format](#) and [openssl-ciphers string format](#) documentation on the OpenSSL website.

## Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your Aurora DB clusters using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB clusters. If they do, you can further check whether those applications require certificate verification to connect.

### Note

Some applications are configured to connect to Aurora PostgreSQL DB clusters only if they can successfully verify the certificate on the server.

For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB clusters. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate \(p. 1644\)](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#). For information about using SSL/TLS with PostgreSQL DB clusters, see [Securing Aurora PostgreSQL data with SSL/TLS \(p. 1029\)](#).

### Topics

- [Determining whether applications are connecting to Aurora PostgreSQL DB clusters using SSL \(p. 1033\)](#)
- [Determining whether a client requires certificate verification in order to connect \(p. 1033\)](#)

- [Updating your application trust store \(p. 1034\)](#)
- [Using SSL/TLS connections for different types of applications \(p. 1034\)](#)

## Determining whether applications are connecting to Aurora PostgreSQL DB clusters using SSL

Check the DB cluster configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see [Working with parameter groups \(p. 215\)](#).

If `rds.force_ssl` isn't set to 1 (on), query the `pg_stat_ssl` view to check connections using SSL. For example, the following query returns only SSL connections and information about the clients using SSL.

```
select datname, username, ssl, client_addr from pg_stat_ssl inner join pg_stat_activity on pg_stat_ssl.pid = pg_stat_activity.pid where ssl is true and username<>'rdsadmin';
```

Only rows using SSL/TLS connections are displayed with information about the connection. The following is sample output.

datname	username	ssl	client_addr
benchdb	pgadmin	t	53.95.6.13
postgres	pgadmin	t	53.95.6.13

(2 rows)

The preceding query displays only the current connections at the time of the query. The absence of results doesn't indicate that no applications are using SSL connections. Other SSL connections might be established at a different time.

## Determining whether a client requires certificate verification in order to connect

When a client, such as `psql` or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as `psql`) and JDBC. The libpq-based clients default to `prefer`, where JDBC clients default to `verify-full`. The certificate on the server is verified only when `sslrootcert` is provided with `sslmode` set to `require`, `verify-ca`, or `verify-full`. An error is thrown if the certificate is invalid.

Use `PGSSLROOTCERT` to verify the certificate with the `PGSSLMODE` environment variable, with `PGSSLMODE` set to `require`, `verify-ca`, or `verify-full`.

```
PGSSLMODE=require PGSSLROOTCERT=/fullpath/rds-ca-2019-root.pem psql -h pgdbidentifier.cxxxxxxxxx.us-east-2.rds.amazonaws.com -U primaryuser -d postgres
```

Use the `sslrootcert` argument to verify the certificate with `sslmode` in connection string format, with `sslmode` set to `require`, `verify-ca`, or `verify-full`.

```
psql "host=pgdbidentifier.cxxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=require sslrootcert=/full/path/rds-ca-2019-root.pem user=primaryuser dbname=postgres"
```

For example, in the preceding case, if you use an invalid root certificate, you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```

## Updating your application trust store

For information about updating the trust store for PostgreSQL applications, see [Secure TCP/IP connections with SSL](#) in the PostgreSQL documentation.

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

## Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store \(p. 1651\)](#).

## Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**

The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are `sslmode` (environment variable `PGSSLMODE`), `sslrootcert` (environment variable `PGSSLROOTCERT`).

For the complete list of options, see [Parameter key words](#) in the PostgreSQL documentation. For the complete list of environment variables, see [Environment variables](#) in the PostgreSQL documentation.

- **pgAdmin**

This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.

For information about configuring connections, see the [pgAdmin documentation](#).

- **JDBC**

JDBC enables database connections with Java applications.

For general information about connecting to a PostgreSQL database with JDBC, see [Connecting to the database](#) in the PostgreSQL documentation. For information about connecting with SSL/TLS, see [Configuring the client](#) in the PostgreSQL documentation.

- **Python**

A popular Python library for connecting to PostgreSQL databases is `psycopg2`.

For information about using `psycopg2`, see the [psycopg2 documentation](#). For a short tutorial on how to connect to a PostgreSQL database, see [Psycopg2 tutorial](#). You can find information about the options the `connect` command accepts in [The psycopg2 module content](#).

**Important**

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance \(p. 1644\)](#).

## Using Kerberos authentication with Aurora PostgreSQL

You can use Kerberos to authenticate users when they connect to your DB cluster running PostgreSQL. In this case, your DB instance works with AWS Directory Service for Microsoft Active Directory to enable Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD.

You create an AWS Managed Microsoft AD directory to store user credentials. You then provide to your PostgreSQL DB cluster the Active Directory's domain and other information. When users authenticate with the PostgreSQL DB cluster, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple DB clusters. Using a directory can also improve your overall security profile.

You can also access credentials from your own on-premises Microsoft Active Directory. To do so you create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL clusters with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use Kerberos, AWS Identity and Access Management (IAM), or both Kerberos and IAM authentication. However, since Kerberos and IAM authentication provide different authentication methods, a specific user can log in to a database using only one or the other authentication method but not both. For more information about IAM authentication, see [IAM database authentication \(p. 1683\)](#).

### Topics

- [Region and version availability \(p. 1035\)](#)
- [Overview of Kerberos authentication for PostgreSQL DB clusters \(p. 1036\)](#)
- [Setting up Kerberos authentication for PostgreSQL DB clusters \(p. 1037\)](#)
- [Managing a DB cluster in a Domain \(p. 1046\)](#)
- [Connecting to PostgreSQL with Kerberos authentication \(p. 1047\)](#)

## Region and version availability

Kerberos authentication is supported on the following engine versions:

- All PostgreSQL 14 and PostgreSQL 13 versions
- PostgreSQL 12.4 and higher 12 versions
- PostgreSQL 11.6 and higher 11 versions
- PostgreSQL 10.11 and higher 10 versions

For more information, see [Amazon Aurora PostgreSQL releases and engine versions \(p. 1414\)](#).

Amazon Aurora supports Kerberos authentication for PostgreSQL DB clusters in the following AWS Regions:

Region name	Region
US East (Ohio)	us-east-2
US East (N. Virginia)	us-east-1
US West (N. California)	us-west-1
US West (Oregon)	us-west-2
Asia Pacific (Mumbai)	ap-south-1
Asia Pacific (Seoul)	ap-northeast-2
Asia Pacific (Singapore)	ap-southeast-1
Asia Pacific (Sydney)	ap-southeast-2
Asia Pacific (Tokyo)	ap-northeast-1
Canada (Central)	ca-central-1
China (Beijing)	cn-north-1
China (Ningxia)	cn-northwest-1
Europe (Frankfurt)	eu-central-1
Europe (Ireland)	eu-west-1
Europe (London)	eu-west-2
Europe (Paris)	eu-west-3
Europe (Stockholm)	eu-north-1
South America (São Paulo)	sa-east-1

## Overview of Kerberos authentication for PostgreSQL DB clusters

To set up Kerberos authentication for a PostgreSQL DB cluster, take the following steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the cluster.
2. Create a role that provides Amazon Aurora access to make calls to your AWS Managed Microsoft AD directory. To do so, create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default

in all AWS Regions, and you can use them without any further actions. For more information, see [Activating and deactivating AWS STS in an AWS Region](#) in the *IAM User Guide*.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see [Manage users and groups in AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.
4. If you plan to locate the directory and the DB instance in different AWS accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see [What is VPC peering?](#) in the *Amazon VPC Peering Guide*.
5. Create or modify a PostgreSQL DB cluster either from the console, CLI, or RDS API using one of the following methods:
  - [Creating a DB cluster and connecting to a database on an Aurora PostgreSQL DB cluster](#) (p. 100)
  - [Modifying an Amazon Aurora DB cluster](#) (p. 248)
  - [Restoring from a DB cluster snapshot](#) (p. 375)
  - [Restoring a DB cluster to a specified time](#) (p. 415)

You can locate the cluster in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the PostgreSQL DB cluster, do the following:

- Provide the domain identifier (`d-*` identifier) that was generated when you created your directory.
  - Provide the name of the IAM role that you created.
  - Ensure that the DB instance security group can receive inbound traffic from the directory security group.
6. Use the RDS master user credentials to connect to the PostgreSQL DB cluster. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB cluster using Kerberos authentication.

## Setting up Kerberos authentication for PostgreSQL DB clusters

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB cluster. To set up Kerberos authentication, take the following steps.

### Topics

- [Step 1: Create a directory using AWS Managed Microsoft AD](#) (p. 1037)
- [Step 2: \(Optional\) create a trust for an on-premises Active Directory](#) (p. 1041)
- [Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service](#) (p. 1042)
- [Step 4: Create and configure users](#) (p. 1043)
- [Step 5: Enable cross-VPC traffic between the directory and the DB instance](#) (p. 1043)
- [Step 6: Create or modify a PostgreSQL DB cluster](#) (p. 1044)
- [Step 7: Create Kerberos authentication PostgreSQL logins](#) (p. 1045)
- [Step 8: Configure a PostgreSQL client](#) (p. 1045)

## Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the user name `Admin` and the specified password. You use this account to manage your directory.

**Important**

Make sure to save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the PostgreSQL DB cluster.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The `Admin` account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The `Admin` account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

## To create a directory with AWS Managed Microsoft AD

1. In the [AWS Directory Service console](#) navigation pane, choose **Directories**, and then choose **Set up directory**.
2. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option currently supported for use with Amazon Aurora.
3. Choose **Next**.
4. On the **Enter directory information** page, provide the following information:

### **Edition**

Choose the edition that meets your requirements.

### **Directory DNS name**

The fully qualified name for the directory, such as `corp.example.com`.

#### Directory NetBIOS name

An optional short name for the directory, such as CORP.

#### Directory description

An optional description for the directory.

#### Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Nonalphanumeric characters (~!@#\$%^&\*\_+=`|\{}{};:"'<>,./?)

#### Confirm password

Retype the administrator password.

#### Important

Make sure that you save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

5. Choose **Next**.
6. On the **Choose VPC and subnets** page, provide the following information:

#### VPC

Choose the VPC for the directory. You can create the PostgreSQL DB cluster in this same VPC or in a different VPC.

#### Subnets

Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose **Next**.
8. Review the directory information. If changes are needed, choose **Previous** and make the changes. When the information is correct, choose **Create directory**.

## Review & create

**Review**

Directory type	VPC
Microsoft AD	vpc-8b6b78e9 ( [REDACTED] )
Directory DNS name	Subnets
corp.example.com	subnet-75128d10 ( [REDACTED], us-east-1a) subnet-f51665dd ( [REDACTED], us-east-1b)
Directory NetBIOS name	
CORP	
Directory description	
My directory	

**Pricing**

Edition	Free trial eligible <a href="#">Learn more</a> 30-day limited trial
Standard	
~USD [REDACTED] *	
* Includes two domain controllers, USD [REDACTED] /mo for each additional domain controller.	

[Cancel](#) [Previous](#) [Create directory](#)

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID** value. You need this value when you create or modify your PostgreSQL DB instance.

The screenshot shows the 'Directory details' page for a Microsoft AD directory. The 'Directory ID' field, which contains the value 'd-90670a8d36', is circled in red. Other visible fields include 'Directory type' (Microsoft AD), 'Edition' (Standard), 'Status' (Active), 'Subnets' (subnet-7d36a227, subnet-a2ab49c6), 'Last updated' (Tuesday, January 7, 2020), 'Launch time' (Tuesday, January 7, 2020), 'Availability zones' (us-east-1c, us-east-1d), 'DNS address' (redacted), 'Directory DNS name' (corp.example.com), 'Directory NetBIOS name' (CORP), and a 'Description' field containing 'My directory'. At the bottom, there are tabs for 'Application management' (which is active), 'Scale & share', 'Networking & security', and 'Maintenance'.

## Step 2: (Optional) create a trust for an on-premises Active Directory

If you don't plan to use your own on-premises Microsoft Active Directory, skip to [Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service \(p. 1042\)](#).

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in [Step 1: Create a directory using AWS Managed Microsoft AD \(p. 1037\)](#)). The trust can be one-way, where the AWS Managed Microsoft AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using AWS Directory Service, see [When to create a trust relationship in the AWS Directory Service Administration Guide](#).

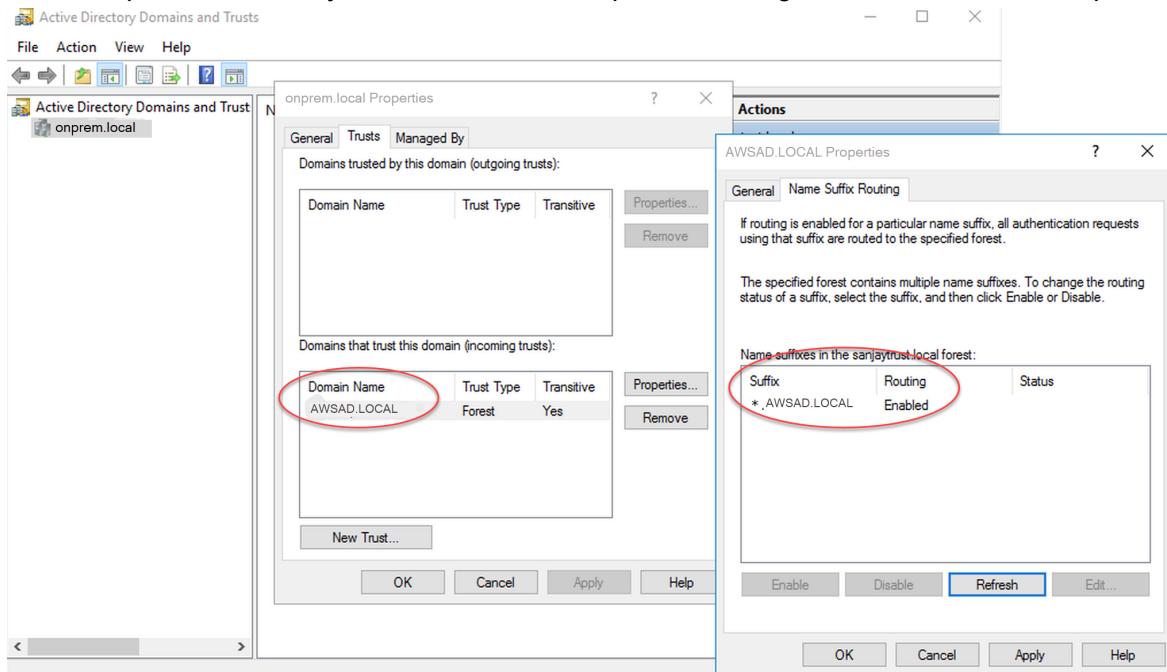

### Note

If you use an on-premises Microsoft Active Directory:

- Windows clients must connect using specialized endpoints as described in [Connecting to PostgreSQL with Kerberos authentication \(p. 1047\)](#).
- Windows clients can't connect with custom endpoints ([p. 38](#)).

- For [global databases \(p. 151\)](#):
  - Windows clients can connect using instance endpoints or cluster endpoints in the primary AWS Region of the global database.
  - Windows clients can't connect using cluster endpoints in secondary AWS Regions.

Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

## Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service

For Amazon Aurora to call AWS Directory Service for you, an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess` is required. This role allows Amazon Aurora to make calls to AWS Directory Service. (Note that this IAM role to access the AWS Directory Service is different than the IAM role used for [IAM database authentication \(p. 1683\)](#).)

When a DB instance is created using the AWS Management Console and the console user has the `iam:CreateRole` permission, the console creates this role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, create the IAM role manually. Choose **RDS** and then **RDS - Directory Service**. Attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to this role.

For more information about creating IAM roles for a service, see [Creating a role to delegate permissions to an AWS service](#) in the [IAM User Guide](#).

### Note

The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon Aurora.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy `AmazonRDSDirectoryServiceAccess`. In this case, the IAM role must have the following IAM trust policy.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "",
    "Effect": "Allow",
    "Principal": {
      "Service": [
        "directoryservice.rds.amazonaws.com",
        "rds.amazonaws.com"
      ]
    },
    "Action": "sts:AssumeRole"
  }
]
```

The role must also have the following IAM role policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

## Step 4: Create and configure users

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. In this case, *users* are individual people or entities who have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance. Also, this EC2 instance must be a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see [Create a user](#) in the *AWS Directory Service Administration Guide*.

## Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB cluster in the same VPC, skip this step and move on to [Step 6: Create or modify a PostgreSQL DB cluster \(p. 1044\)](#).

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or [AWS Transit Gateway](#).

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in [What is VPC peering?](#) in the *Amazon Virtual Private Cloud Peering Guide*.

### To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.

2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

#### To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in [Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join](#) in the *AWS Directory Service Administration Guide*.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this directory ID to join the DB instance to the domain.

## Step 6: Create or modify a PostgreSQL DB cluster

Create or modify a PostgreSQL DB cluster for use with your directory. You can use the console, CLI, or RDS API to associate a DB cluster with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB cluster using the console, the [create-db-cluster](#) CLI command, or the [CreateDBCluster](#) RDS API operation. For instructions, see [Creating a DB cluster and connecting to a database on an Aurora PostgreSQL DB cluster \(p. 100\)](#).
- Modify an existing PostgreSQL DB cluster using the console, the [modify-db-cluster](#) CLI command, or the [ModifyDBCluster](#) RDS API operation. For instructions, see [Modifying an Amazon Aurora DB cluster \(p. 248\)](#).
- Restore a PostgreSQL DB cluster from a DB snapshot using the console, the [restore-db-cluster-from-db-snapshot](#) CLI command, or the [RestoreDBClusterFromDBSnapshot](#) RDS API operation. For instructions, see [Restoring from a DB cluster snapshot \(p. 375\)](#).
- Restore a PostgreSQL DB cluster to a point-in-time using the console, the [restore-db-instance-to-point-in-time](#) CLI command, or the [RestoreDBClusterToPointInTime](#) RDS API operation. For instructions, see [Restoring a DB cluster to a specified time \(p. 415\)](#).

Kerberos authentication is only supported for PostgreSQL DB clusters in a VPC. The DB cluster can be in the same VPC as the directory, or in a different VPC. The DB cluster must use a security group that allows ingress and egress within the directory's VPC so the DB cluster can communicate with the directory.

#### Console

When you use the console to create, modify, or restore a DB cluster, choose **Kerberos authentication** in the **Database authentication** section. Then choose **Browse Directory**. Select the directory or choose **Create a new directory** to use the Directory Service.

#### AWS CLI

When you use the AWS CLI, the following parameters are required for the DB cluster to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-\*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB cluster to use a directory.

```
aws rds modify-db-cluster --db-cluster-identifier mydbinstance --domain d-Directory-ID --domain-iam-role-name role-name
```

**Important**

If you modify a DB cluster to enable Kerberos authentication, reboot the DB cluster after making the change.

## Step 7: Create Kerberos authentication PostgreSQL logins

Use the RDS master user credentials to connect to the PostgreSQL DB cluster as you do with any other DB cluster . The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision PostgreSQL logins and users from the Microsoft Active Directory users and groups in your domain. To manage database permissions, you grant and revoke standard PostgreSQL permissions to these logins.

To allow an Active Directory user to authenticate with PostgreSQL, use the RDS master user credentials. You use these credentials to connect to the PostgreSQL DB cluster as you do with any other DB cluster . After you're logged in, create an externally authenticated user in PostgreSQL and grant the `rds_ad` role to this user.

```
CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;  
GRANT rds_ad TO "username@CORP.EXAMPLE.COM";
```

Replace `username` with the user name and include the domain name in uppercase. Users (both humans and applications) from your domain can now connect to the RDS PostgreSQL cluster from a domain-joined client machine using Kerberos authentication.

Note that a database user can use either Kerberos or IAM authentication but not both, so this user can't also have the `rds_iam` role. This also applies to nested memberships. For more information, see [IAM database authentication \(p. 1683\)](#).

## Step 8: Configure a PostgreSQL client

To configure a PostgreSQL client, take the following steps:

- Create a `krb5.conf` file (or equivalent) to point to the domain.
- Verify that traffic can flow between the client host and AWS Directory Service. Use a network utility such as Netcat for the following:
  - Verify traffic over DNS for port 53.
  - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for AWS Directory Service.
- Verify that traffic can flow between the client host and the DB instance over the database port. For example, use `psql` to connect and access the database.

The following is sample `krb5.conf` content for AWS Managed Microsoft AD.

```
[libdefaults]  
default_realm = EXAMPLE.COM  
[realms]  
EXAMPLE.COM = {  
    kdc = example.com  
    admin_server = example.com  
}  
[domain_realm]
```

```
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
```

The following is sample krb5.conf content for an on-premises Microsoft Active Directory.

```
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
}
ONPREM.COM = {
    kdc = onprem.com
    admin_server = onprem.com
}
[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
.onprem.com = ONPREM.COM
onprem.com = ONPREM.COM
.rds.amazonaws.com = EXAMPLE.COM
.amazonaws.com.cn = EXAMPLE.COM
.amazon.com = EXAMPLE.COM
```

## Managing a DB cluster in a Domain

You can use the console, the CLI, or the RDS API to manage your DB cluster and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB cluster to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the [modify-db-cluster](#) CLI command. Specify the current membership's directory ID for the --domain option.
- To disable Kerberos authentication on a DB instance, use the [modify-db-cluster](#) CLI command. Specify none for the --domain option.
- To move a DB instance from one domain to another, use the [modify-db-cluster](#) CLI command. Specify the domain identifier of the new domain for the --domain option.

## Understanding Domain membership

After you create or modify your DB cluster, the DB instances become members of the domain. You can view the status of the domain membership in the console or by running the [describe-db-instances](#) CLI command. The status of the DB instance can be one of the following:

- **kerberos-enabled** – The DB instance has Kerberos authentication enabled.
- **enabling-kerberos** – AWS is in the process of enabling Kerberos authentication on this DB instance.
- **pending-enable-kerberos** – Enabling Kerberos authentication is pending on this DB instance.
- **pending-maintenance-enable-kerberos** – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **pending-disable-kerberos** – Disabling Kerberos authentication is pending on this DB instance.
- **pending-maintenance-disable-kerberos** – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.

- **enable-kerberos-failed** – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- **disabling-kerberos** – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB cluster. If so, make sure that you are using the correct IAM role, then modify the DB cluster to join the domain.

## Connecting to PostgreSQL with Kerberos authentication

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command-line interface such as psql. For more information about connecting, see [Connecting to an Amazon Aurora PostgreSQL DB cluster \(p. 212\)](#). For information about obtaining the endpoint, port number, and other details needed for connection, see [Viewing the endpoints for an Aurora cluster \(p. 37\)](#).

### pgAdmin

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, enter a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, enter the following information from your Aurora PostgreSQL database.
  - For **Host**, enter the endpoint for the Writer instance of your Aurora PostgreSQL DB cluster. An endpoint looks similar to the following:

```
AUR-cluster-instance.111122223333.aws-region.rds.amazonaws.com
```

To connect to an on-premises Microsoft Active Directory from a Windows client, you use the domain name of the AWS Managed Active Directory instead of `rds.amazonaws.com` in the host endpoint. For example, suppose that the domain name for the AWS Managed Active Directory is `corp.example.com`. Then for **Host**, the endpoint would be specified as follows:

```
AUR-cluster-instance.111122223333.aws-region.corp.example.com
```

- For **Port**, enter the assigned port.
- For **Maintenance database**, enter the name of the initial database to which the client will connect.
- For **Username**, enter the user name that you entered for Kerberos authentication in [Step 7: Create Kerberos authentication PostgreSQL logins \(p. 1045\)](#).

5. Choose **Save**.

### Psq

To use psql to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

```
kinit username
```

Replace `username` with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB cluster is using a publicly accessible VPC, put a private IP address for your DB cluster endpoint in your `/etc/hosts` file on the EC2 client. For example, the following commands obtain the private IP address and then put it in the `/etc/hosts` file.

```
% dig +short PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com
;; Truncated, retrying in TCP mode.
ec2-34-210-197-118.AWS-Region.compute.amazonaws.com.
34.210.197.118

% echo " 34.210.197.118  PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/hosts
```

If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the AWS Managed Active Directory.

For example, suppose that the domain name for your AWS Managed Active Directory is `corp.example.com`. Then use the format `PostgreSQL-endpoint.AWS-Region.corp.example.com` for the endpoint and put it in the `/etc/hosts` file.

```
% echo " 34.210.197.118  PostgreSQL-endpoint.AWS-Region.corp.example.com" >> /etc/hosts
```

3. Use the following `psql` command to log in to a PostgreSQL DB cluster that is integrated with Active Directory. Use a cluster or instance endpoint.

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com postgres
```

To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following `psql` command with the domain name from the previous step (`corp.example.com`):

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.corp.example.com postgres
```

## Migrating data to Amazon Aurora with PostgreSQL compatibility

You have several options for migrating data from your existing database to an Amazon Aurora PostgreSQL-Compatible Edition DB cluster. Your migration options also depend on the database that you are migrating from and the size of the data that you are migrating. Following are your options:

### [Migrating an RDS for PostgreSQL DB instance using a snapshot \(p. 1049\)](#)

You can migrate data directly from an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster.

### [Migrating an RDS for PostgreSQL DB instance using an Aurora read replica \(p. 1054\)](#)

You can also migrate from an RDS for PostgreSQL DB instance by creating an Aurora PostgreSQL read replica of an RDS for PostgreSQL DB instance. When the replica lag between the RDS for

PostgreSQL DB instance and the Aurora PostgreSQL read replica is zero, you can stop replication. At this point, you can make the Aurora read replica a standalone Aurora PostgreSQL DB cluster for reading and writing.

#### **Importing data from Amazon S3 into Aurora PostgreSQL (p. 1230)**

You can migrate data by importing it from Amazon S3 into a table belonging to an Aurora PostgreSQL DB cluster.

#### **Migrating from a database that is not PostgreSQL-compatible**

You can use AWS Database Migration Service (AWS DMS) to migrate data from a database that is not PostgreSQL-compatible. For more information on AWS DMS, see [What is AWS Database Migration Service?](#) in the *AWS Database Migration Service User Guide*.

For a list of AWS Regions where Aurora is available, see [Amazon Aurora](#) in the *AWS General Reference*.

#### **Important**

If you plan to migrate an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster in the near future, we strongly recommend that you turn off auto minor version upgrades for the DB instance early in the migration planning phase. Migration to Aurora PostgreSQL might be delayed if the RDS for PostgreSQL version isn't yet supported by Aurora PostgreSQL.

For information about Aurora PostgreSQL versions, see [Engine versions for Amazon Aurora PostgreSQL](#).

## **Migrating a snapshot of an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster**

To create an Aurora PostgreSQL DB cluster, you can migrate a DB snapshot of an RDS for PostgreSQL DB instance. The new Aurora PostgreSQL DB cluster is populated with the data from the original RDS for PostgreSQL DB instance. For information about creating a DB snapshot, see [Creating a DB snapshot](#).

In some cases, the DB snapshot might not be in the AWS Region where you want to locate your data. If so, use the Amazon RDS console to copy the DB snapshot to that AWS Region. For information about copying a DB snapshot, see [Copying a DB snapshot](#).

You can migrate RDS for PostgreSQL snapshots that are compatible with the Aurora PostgreSQL versions available in the given AWS Region. For example, you can migrate a snapshot from an RDS for PostgreSQL 11.1 DB instance to Aurora PostgreSQL version 11.4, 11.7, 11.8, or 11.9 in the US West (N. California) Region. You can migrate RDS for PostgreSQL 10.11 snapshot to Aurora PostgreSQL 10.11, 10.12, 10.13, and 10.14. In other words, the RDS for PostgreSQL snapshot must use the same or a lower minor version as the Aurora PostgreSQL.

You can also choose for your new Aurora PostgreSQL DB cluster to be encrypted at rest by using an AWS KMS key. This option is available only for unencrypted DB snapshots.

To migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster, you can use the AWS Management Console, the AWS CLI, or the RDS API. When you use the AWS Management Console, the console takes the actions necessary to create both the DB cluster and the primary instance.

### **Console**

#### **To migrate a PostgreSQL DB snapshot by using the RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. Choose **Snapshots**.
3. On the **Snapshots** page, choose the RDS for PostgreSQL snapshot that you want to migrate into an Aurora PostgreSQL DB cluster.
4. Choose **Actions** then choose **Migrate snapshot**.
5. Set the following values on the **Migrate database** page:
  - **DB engine version:** Choose a DB engine version you want to use for the new migrated instance.
  - **DB instance identifier:** Enter a name for the DB cluster that is unique for your account in the AWS Region that you chose. This identifier is used in the endpoint addresses for the instances in your DB cluster. You might choose to add some intelligence to the name, such as including the AWS Region and DB engine that you chose, for example **aurora-cluster1**.

The DB instance identifier has the following constraints:

- It must contain 1–63 alphanumeric characters or hyphens.
- Its first character must be a letter.
- It can't end with a hyphen or contain two consecutive hyphens.
- It must be unique for all DB instances per AWS account, per AWS Region.
- **DB instance class:** Choose a DB instance class that has the required storage and capacity for your database, for example `db.r6g.large`. Aurora cluster volumes automatically grow as the amount of data in your database increases. So you only need to choose a DB instance class that meets your current storage requirements. For more information, see [Overview of Aurora storage \(p. 67\)](#).
- **Virtual private cloud (VPC):** If you have an existing VPC, then you can use that VPC with your Aurora PostgreSQL DB cluster by choosing your VPC identifier, for example `vpc-a464d1c1`. For information about creating a VPC, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\) \(p. 1744\)](#).

Otherwise, you can choose to have Amazon RDS create a VPC for you by choosing **Create new VPC**.

- **DB subnet group:** If you have an existing subnet group, then you can use that subnet group with your Aurora PostgreSQL DB cluster by choosing your subnet group identifier, for example `gs-subnet-group1`.
- **Public access:** Choose **No** to specify that instances in your DB cluster can only be accessed by resources inside of your VPC. Choose **Yes** to specify that instances in your DB cluster can be accessed by resources on the public network.

#### Note

Your production DB cluster might not need to be in a public subnet, because only your application servers require access to your DB cluster. If your DB cluster doesn't need to be in a public subnet, set **Public access to No**.

- **VPC security group:** Choose a VPC security group to allow access to your database.
- **Availability Zone:** Choose the Availability Zone to host the primary instance for your Aurora PostgreSQL DB cluster. To have Amazon RDS choose an Availability Zone for you, choose **No preference**.
- **Database port:** Enter the default port to be used when connecting to instances in the Aurora PostgreSQL DB cluster. The default is 5432.

#### Note

You might be behind a corporate firewall that doesn't allow access to default ports such as the PostgreSQL default port, 5432. In this case, provide a port value that your corporate firewall allows. Remember that port value later when you connect to the Aurora PostgreSQL DB cluster.

- **Enable Encryption:** Choose **Enable Encryption** for your new Aurora PostgreSQL DB cluster to be encrypted at rest. Also choose a KMS key as the **AWS KMS key** value.

- **Auto minor version upgrade:** Choose **Enable auto minor version upgrade** to enable your Aurora PostgreSQL DB cluster to receive minor PostgreSQL DB engine version upgrades automatically when they become available.

The **Auto minor version upgrade** option only applies to upgrades to PostgreSQL minor engine versions for your Aurora PostgreSQL DB cluster. It doesn't apply to regular patches applied to maintain system stability.

6. Choose **Migrate** to migrate your DB snapshot.
7. Choose **Databases** to see the new DB cluster. Choose the new DB cluster to monitor the progress of the migration. On the **Connectivity & security** tab, you can find the cluster endpoint to use for connecting to the primary writer instance of the DB cluster. For more information on connecting to an Aurora PostgreSQL DB cluster, see [Connecting to an Amazon Aurora DB cluster \(p. 207\)](#).

## AWS CLI

Using the AWS CLI to migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL involves two separate AWS CLI commands. First, you use the `restore-db-cluster-from-snapshot` AWS CLI command create a new Aurora PostgreSQL DB cluster. You then use the `create-db-instance` command to create the primary DB instance in the new cluster to complete the migration. The following procedure creates an Aurora PostgreSQL DB cluster with primary DB instance that has the same configuration as the DB instance used to create the snapshot.

### To migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster

1. Use the `describe-db-snapshots` command to obtain information about the DB snapshot you want to migrate. You can specify either the `--db-instance-identifier` parameter or the `--db-snapshot-identifier` in the command. If you don't specify one of these parameters, you get all snapshots.

```
aws rds describe-db-snapshots --db-instance-identifier <your-db-instance-name>
```

2. The command returns all configuration details for any snapshots created from the DB instance specified. In the output, find the snapshot that you want to migrate and locate its Amazon Resource Name (ARN). To learn more about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#). An ARN looks similar to the output following.

```
"DBSnapshotArn": "arn:aws:rds:aws-region:111122223333:snapshot:<snapshot_name>"
```

Also in the output you can find configuration details for the RDS for PostgreSQL DB instance, such as the engine version, allocated storage, whether or not the DB instance is encrypted, and so on.

3. Use the `restore-db-cluster-from-snapshot` command to start the migration. Specify the following parameters:
  - `--db-cluster-identifier` – The name that you want to give to the Aurora PostgreSQL DB cluster. This Aurora DB cluster is the target for your DB snapshot migration.
  - `--snapshot-identifier` – The Amazon Resource Name (ARN) of the DB snapshot to migrate.
  - `--engine` – Specify `aurora-postgresql` for the Aurora DB cluster engine.
  - `--kms-key-id` – This optional parameter lets you create an encrypted Aurora PostgreSQL DB cluster from an unencrypted DB snapshot. It also lets you choose a different encryption key for the DB cluster than the key used for the DB snapshot.

#### Note

You can't create an unencrypted Aurora PostgreSQL DB cluster from an encrypted DB snapshot.

Without the `--kms-key-id` parameter specified as shown following, the [restore-db-cluster-from-snapshot](#) AWS CLI command creates an empty Aurora PostgreSQL DB cluster that's either encrypted using the same key as the DB snapshot or is unencrypted if the source DB snapshot isn't encrypted.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
    --db-cluster-identifier cluster-name \
    --snapshot-identifier arn:aws:rds:aws-region:111122223333:snapshot:your-snapshot-name \
    --engine aurora-postgresql
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
    --db-cluster-identifier new_cluster ^
    --snapshot-identifier arn:aws:rds:aws-region:111122223333:snapshot:your-snapshot-name ^
    --engine aurora-postgresql
```

4. The command returns details about the Aurora PostgreSQL DB cluster that's being created for the migration. You can check the status of the Aurora PostgreSQL DB cluster by using the [describe-db-clusters](#) AWS CLI command.

```
aws rds describe-db-clusters --db-cluster-identifier cluster-name
```

5. When the DB cluster becomes "available", you use [create-db-instance](#) command to populate the Aurora PostgreSQL DB cluster with the DB instance based on your Amazon RDS DB snapshot. Specify the following parameters:

- `--db-cluster-identifier` – The name of the new Aurora PostgreSQL DB cluster that you created in the previous step.
- `--db-instance-identifier` – The name you want to give to the DB instance. This instance becomes the primary node in your Aurora PostgreSQL DB cluster.
- `--db-instance-class` – Specify the DB instance class to use. Choose from among the DB instance classes supported by the Aurora PostgreSQL version to which you're migrating. For more information, see [DB instance class types \(p. 56\)](#) and [Supported DB engines for DB instance classes \(p. 57\)](#).
- `--engine` – Specify `aurora-postgresql` for the DB instance.

You can also create the DB instance with a different configuration than the source DB snapshot, by passing in the appropriate options in the [create-db-instance](#) AWS CLI command. For more information, see the [create-db-instance](#) command.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-cluster-identifier cluster-name \
    --db-instance-identifier --db-instance-class db.instance.class \
    --engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^
```

```
--db-cluster-identifier cluster-name ^
--db-instance-identifier --db-instance-class db.instance.class ^
--engine aurora-postgresql
```

When the migration process completes, the Aurora PostgreSQL cluster has a populated primary DB instance.

# Migrating data from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster using an Aurora read replica

You can use an RDS for PostgreSQL DB instance as the basis for a new Aurora PostgreSQL DB cluster by using an Aurora read replica for the migration process. The Aurora read replica option is available only for migrating within the same AWS Region and account, and it's available only if the Region offers a compatible version of Aurora PostgreSQL for your RDS for PostgreSQL DB instance. By *compatible*, we mean that the Aurora PostgreSQL version is the same as the RDS for PostgreSQL version, or that it is a higher minor version in the same major version family.

For example, to use this technique to migrate an RDS for PostgreSQL 11.14 DB instance, the Region must offer Aurora PostgreSQL version 11.14 or a higher minor version in the PostgreSQL version 11 family.

## Topics

- [Overview of migrating data by using an Aurora read replica \(p. 1054\)](#)
- [Preparing to migrate data by using an Aurora read replica \(p. 1054\)](#)
- [Creating an Aurora read replica \(p. 1055\)](#)
- [Promoting an Aurora read replica \(p. 1061\)](#)

## Overview of migrating data by using an Aurora read replica

Migrating from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster is a multistep procedure. First, you create an Aurora read replica of your source RDS for PostgreSQL DB instance. That starts a replication process from your RDS for PostgreSQL DB instance to a special-purpose DB cluster known as a *Replica cluster*. The Replica cluster consists solely of an Aurora read replica (a reader instance).

Once the Replica cluster exists, you monitor the lag between it and the source RDS for PostgreSQL DB instance. When the replica lag is zero (0), you can promote the Replica cluster. Replication stops, the Replica cluster is promoted to a standalone Aurora DB cluster, and the reader is promoted to writer instance for the cluster. You can then add instances to the Aurora PostgreSQL DB cluster to size your Aurora PostgreSQL DB cluster for your use case. You can also delete the RDS for PostgreSQL DB instance if you have no further need of it.

### Note

It can take several hours per terabyte of data for the migration to complete.

You can't create an Aurora read replica if your RDS for PostgreSQL DB instance already has an Aurora read replica or if it has a cross-Region read replica.

## Preparing to migrate data by using an Aurora read replica

During the migration process using Aurora read replica, updates made to the source RDS for PostgreSQL DB instance are asynchronously replicated to the Aurora read replica of the Replica cluster. The process uses PostgreSQL's native streaming replication functionality which stores write-ahead logs (WAL) segments on the source instance. Before starting this migration process, make sure that your instance has sufficient storage capacity by checking values for the metrics listed in the table.

Metric	Description
FreeStorageSpace	The available storage space.  Units: Bytes

Metric	Description
OldestReplicationSlotLag	The size of the lag for WAL data in the replica that is lagging the most.  Units: Megabytes
RDSToAuroraPostgreSQLReplicaLag	The amount of time in seconds that an Aurora PostgreSQL DB cluster lags behind the source RDS DB instance.
TransactionLogsDiskUsage	The disk space used by the transaction logs.  Units: Megabytes

For more information about monitoring your RDS instance, see [Monitoring](#) in the *Amazon RDS User Guide*.

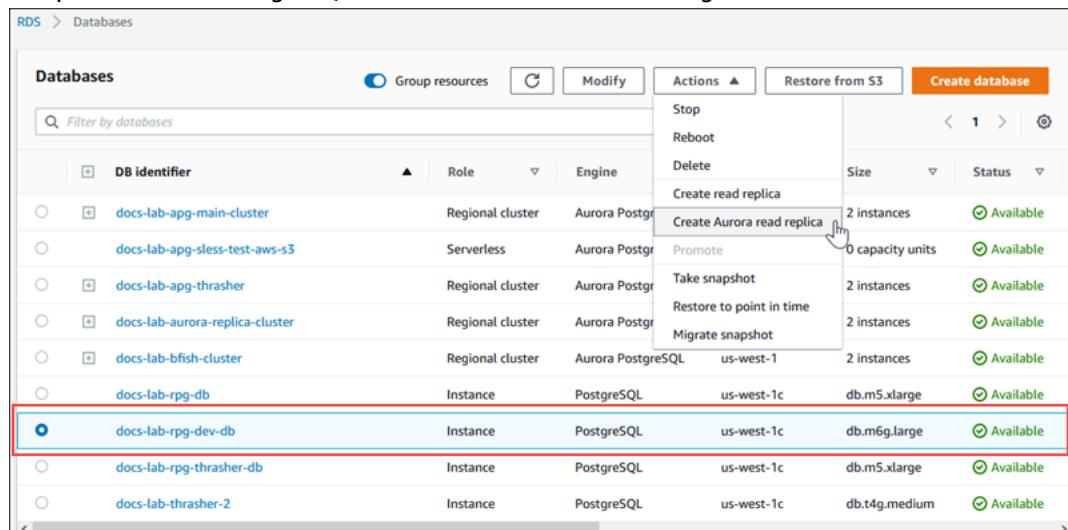

## Creating an Aurora read replica

You can create an Aurora read replica for an RDS for PostgreSQL DB instance by using the AWS Management Console or the AWS CLI. The option to create an Aurora read replica using the AWS Management Console is available only if the AWS Region offers a compatible Aurora PostgreSQL version. That is, it's available only if there's an Aurora PostgreSQL version that is the same as the RDS for PostgreSQL version or a higher minor version in the same major version family.

### Console

#### To create an Aurora read replica from a source PostgreSQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the RDS for PostgreSQL DB instance that you want to use as the source for your Aurora read replica. For **Actions**, choose **Create Aurora read replica**. If this choice doesn't display, it means that a compatible Aurora PostgreSQL version isn't available in the Region.

4. On the Create Aurora read replica settings page, you configure the properties for the Aurora PostgreSQL DB cluster as shown in the following table. The Replica DB cluster is created from a

snapshot of the source DB instance using the same 'master' user name and password as the source, so you can't change these at this time.

Option	Description
<b>DB instance class</b>	Choose a DB instance class that meets the processing and memory requirements primary instance in the DB cluster. For more information, see <a href="#">Aurora DB instance classes (p. 56)</a> .
<b>Multi-AZ deployment</b>	Not available during the migration
<b>DB instance identifier</b>	<p>Enter the name that you want to give to the DB instance. This identifier is used in the endpoint address for the primary instance of the new DB cluster.</p> <p>The DB instance identifier has the following constraints:</p> <ul style="list-style-type: none"> <li>• It must contain 1–63 alphanumeric characters or hyphens.</li> <li>• Its first character must be a letter.</li> <li>• It can't end with a hyphen or contain two consecutive hyphens.</li> <li>• It must be unique for all DB instances for each AWS account, for each AWS Region.</li> </ul>
<b>Virtual Private Cloud (VPC)</b>	Choose the VPC to host the DB cluster. Choose <b>Create new VPC</b> to have Amazon RDS create a VPC for you. For more information, see <a href="#">DB cluster prerequisites (p. 127)</a> .
<b>DB subnet group</b>	Choose the DB subnet group to use for the DB cluster. Choose <b>Create new DB Subnet Group</b> to have Amazon RDS create a DB subnet group for you. For more information, see <a href="#">DB cluster prerequisites (p. 127)</a> .
<b>Public accessibility</b>	Choose <b>Yes</b> to give the DB cluster a public IP address; otherwise, choose <b>No</b> . The instances in your DB cluster can be a mix of both public and private DB instances. For more information about hiding instances from public access, see <a href="#">Hiding a DB cluster in a VPC from the internet (p. 1735)</a> .
<b>Availability zone</b>	Determine if you want to specify a particular Availability Zone. For more information about Availability Zones, see <a href="#">Regions and Availability Zones (p. 11)</a> .
<b>VPC security groups</b>	Choose one or more VPC security groups to secure network access to the DB cluster. Choose <b>Create new VPC security group</b> to have Amazon RDS create a VPC security group for you. For more information, see <a href="#">DB cluster prerequisites (p. 127)</a> .

Option	Description
<b>Database port</b>	Specify the port for applications and utilities to use to access the database. Aurora PostgreSQL DB clusters default to the default PostgreSQL port, 5432. Firewalls at some companies block connections to this port. If your company firewall blocks the default port, choose another port for the new DB cluster.
<b>DB parameter group</b>	Choose a DB parameter group for the Aurora PostgreSQL DB cluster. Aurora has a default DB parameter group you can use, or you can create your own DB parameter group. For more information about DB parameter groups, see <a href="#">Working with parameter groups (p. 215)</a> .
<b>DB cluster parameter group</b>	Choose a DB cluster parameter group for the Aurora PostgreSQL DB cluster. Aurora has a default DB cluster parameter group you can use, or you can create your own DB cluster parameter group. For more information about DB cluster parameter groups, see <a href="#">Working with parameter groups (p. 215)</a> .
<b>Encryption</b>	Choose <b>Enable encryption</b> for your new Aurora DB cluster to be encrypted at rest. If you choose <b>Enable encryption</b> , also choose a KMS key as the <b>AWS KMS key</b> value.
<b>Priority</b>	Choose a failover priority for the DB cluster. If you don't choose a value, the default is <b>tier-1</b> . This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. For more information, see <a href="#">Fault tolerance for an Aurora DB cluster (p. 72)</a> .
<b>Backup retention period</b>	Choose the length of time, 1–35 days, for Aurora to retain backup copies of the database. Backup copies can be used for point-in-time restores (PITR) of your database down to the second.
<b>Enhanced monitoring</b>	Choose <b>Enable enhanced monitoring</b> to enable gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring (p. 518)</a> .
<b>Monitoring Role</b>	Only available if you chose <b>Enable enhanced monitoring</b> . The AWS Identity and Access Management (IAM) role to use for Enhanced Monitoring. For more information, see <a href="#">Setting up and enabling Enhanced Monitoring (p. 519)</a> .
<b>Granularity</b>	Only available if you chose <b>Enable enhanced monitoring</b> . Set the interval, in seconds, between when metrics are collected for your DB cluster.

Option	Description
<b>Auto minor version upgrade</b>	<p>Choose <b>Yes</b> to enable your Aurora PostgreSQL DB cluster to receive minor PostgreSQL DB engine version upgrades automatically when they become available.</p> <p>The <b>Auto minor version upgrade</b> option only applies to upgrades to PostgreSQL minor engine versions for your Aurora PostgreSQL DB cluster. It doesn't apply to regular patches applied to maintain system stability.</p>
<b>Maintenance window</b>	Choose the weekly time range during which system maintenance can occur.

5. Choose **Create read replica**.

### AWS CLI

To create an Aurora read replica from a source RDS for PostgreSQL DB instance by using the AWS CLI, you first use the [create-db-cluster](#) CLI command to create an empty Aurora DB cluster. Once the DB cluster exists, you then use the [create-db-instance](#) command to create the primary instance for your DB cluster. The primary instance is the first instance that's created in an Aurora DB cluster. In this case, it's created initially as an Aurora read replica of your RDS for PostgreSQL DB instance. When the process concludes, your RDS for PostgreSQL DB instance has effectively been migrated to an Aurora PostgreSQL DB cluster.

You don't need to specify the main user account (typically, `postgres`), its password, or the database name. The Aurora read replica obtains these automatically from the source RDS for PostgreSQL DB instance that you identify when you invoke the AWS CLI commands.

You do need to specify the engine version to use for the Aurora PostgreSQL DB cluster and the DB instance. The version you specify should match the source RDS for PostgreSQL DB instance. If the source RDS for PostgreSQL DB instance is encrypted, you need to also specify encryption for the Aurora PostgreSQL DB cluster primary instance. Migrating an encrypted instance to an unencrypted Aurora DB cluster isn't supported.

The following examples create an Aurora PostgreSQL DB cluster named `my-new-aurora-cluster` that's going to use an unencrypted RDS DB source instance. You first create the Aurora PostgreSQL DB cluster by calling the [create-db-cluster](#) CLI command. The example shows how to use the optional `--storage-encrypted` parameter to specify that the DB cluster should be encrypted. Because the source DB isn't encrypted, the `--kms-key-id` is used to specify the key to use. For more information about required and optional parameters, see the list following the example.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
--db-cluster-identifier my-new-aurora-cluster \
--db-subnet-group-name my-db-subnet \
--vpc-security-group-ids sg-11111111 \
--engine aurora-postgresql \
--engine-version same-as-your-rds-instance-version \
--replication-source-identifier arn:aws:rds:aws-region:111122223333:db/rpg-source-db \
--storage-encrypted \
--kms-key-id arn:aws:kms:aws-region:111122223333:key/11111111-2222-3333-444444444444
```

For Windows:

```
aws rds create-db-cluster ^
```

```
--db-cluster-identifier my-new-aurora-cluster ^
--db-subnet-group-name my-db-subnet ^
--vpc-security-group-ids sg-11111111 ^
--engine aurora-postgresql ^
--engine-version same-as-your-rds-instance-version ^
--replication-source-identifier arn:aws:rds:aws-region:111122223333:db/rpg-source-db ^
--storage-encrypted ^
--kms-key-id arn:aws:kms:aws-region:111122223333:key/11111111-2222-3333-444444444444
```

In the following list you can find more information about some of the options shown in the example. Unless otherwise specified, these parameters are required.

- **--db-cluster-identifier** – You need to give your new Aurora PostgreSQL DB cluster a name.
- **--db-subnet-group-name** – Create your Aurora PostgreSQL DB cluster in the same DB subnet as the source DB instance.
- **--vpc-security-group-ids** – Specify the security group for your Aurora PostgreSQL DB cluster.
- **--engine-version** – Specify the version to use for the Aurora PostgreSQL DB cluster. This should be the same as the version used by your source RDS for PostgreSQL DB instance.
- **--replication-source-identifier** – Identify your RDS for PostgreSQL DB instance using its Amazon Resource Name (ARN). For more information about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#) in the *AWS General Reference*. of your DB cluster.
- **--storage-encrypted** – Optional. Use only when needed to specify encryption as follows:
  - Use this parameter when the source DB instance has encrypted storage. The call to [create-db-cluster](#) fails if you don't use this parameter with a source DB instance that has encrypted storage. If you want to use a different key for the Aurora PostgreSQL DB cluster than the key used by the source DB instance, you need to also specify the **--kms-key-id**.
  - Use if the source DB instance's storage is unencrypted but you want the Aurora PostgreSQL DB cluster to use encryption. If so, you also need to identify the encryption key to use with the **--kms-key-id** parameter.
- **--kms-key-id** – Optional. When used, you can specify the key to use for storage encryption (**--storage-encrypted**) by using the key's ARN, ID, alias ARN, or its alias name. This parameter is needed only for the following situations:
  - To choose a different key for the Aurora PostgreSQL DB cluster than that used by the source DB instance.
  - To create an encrypted cluster from an unencrypted source. In this case, you need to specify the key that Aurora PostgreSQL should use for encryption.

After creating the Aurora PostgreSQL DB cluster, you then create the primary instance by using the [create-db-instance](#) CLI command, as shown in the following:

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-cluster-identifier my-new-aurora-cluster \
--db-instance-class db.x2g.16xlarge \
--db-instance-identifier rpg-for-migration \
--engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^
--db-cluster-identifier my-new-aurora-cluster ^
--db-instance-class db.x2g.16xlarge ^
--db-instance-identifier rpg-for-migration ^
--engine aurora-postgresql
```

In the following list, you can find more information about some of the options shown in the example.

- `--db-cluster-identifier` – Specify the name of the Aurora PostgreSQL DB cluster that you created with the [create-db-instance](#) command in the previous steps.
- `--db-instance-class` – The name of the DB instance class to use for your primary instance, such as `db.r4.xlarge`, `db.t4g.medium`, `db.x2g.16xlarge`, and so on. For a list of available DB instance classes, see [DB instance class types \(p. 56\)](#).
- `--db-instance-identifier` – Specify the name to give your primary instance.
- `--engine aurora-postgresql` – Specify `aurora-postgresql` for the engine.

## RDS API

To create an Aurora read replica from a source RDS for PostgreSQL DB instance, first use the RDS API operation [CreateDBCluster](#) to create a new Aurora DB cluster for the Aurora read replica that gets created from your source RDS for PostgreSQL DB instance. When the Aurora PostgreSQL DB cluster is available, you then use the [CreateDBInstance](#) to create the primary instance for the Aurora DB cluster.

You don't need to specify the main user account (typically, `postgres`), its password, or the database name. The Aurora read replica obtains these automatically from the source RDS for PostgreSQL DB instance specified with `ReplicationSourceIdentifier`.

You do need to specify the engine version to use for the Aurora PostgreSQL DB cluster and the DB instance. The version you specify should match the source RDS for PostgreSQL DB instance. If the source RDS for PostgreSQL DB instance is encrypted, you need to also specify encryption for the Aurora PostgreSQL DB cluster primary instance. Migrating an encrypted instance to an unencrypted Aurora DB cluster isn't supported.

To create the Aurora DB cluster for the Aurora read replica, use the RDS API operation [CreateDBCluster](#) with the following parameters:

- `DBClusterIdentifier` – The name of the DB cluster to create.
- `DBSubnetGroupName` – The name of the DB subnet group to associate with this DB cluster.
- `Engine=aurora-postgresql` – The name of the engine to use.
- `ReplicationSourceIdentifier` – The Amazon Resource Name (ARN) for the source PostgreSQL DB instance. For more information about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#) in the *Amazon Web Services General Reference*. If `ReplicationSourceIdentifier` identifies an encrypted source, Amazon RDS uses your default KMS key unless you specify a different key using the `KmsKeyId` option.
- `VpcSecurityGroupIds` – The list of Amazon EC2 VPC security groups to associate with this DB cluster.
- `StorageEncrypted` – Indicates that the DB cluster is encrypted. When you use this parameter without also specifying the `ReplicationSourceIdentifier`, Amazon RDS uses your default KMS key.
- `KmsKeyId` – The key for an encrypted cluster. When used, you can specify the key to use for storage encryption by using the key's ARN, ID, alias ARN, or its alias name.

For more information, see [CreateDBCluster](#) in the *Amazon RDS API Reference*.

Once the Aurora DB cluster is available, you can then create a primary instance for it by using the RDS API operation [CreateDBInstance](#) with the following parameters:

- `DBClusterIdentifier` – The name of your DB cluster.
- `DBInstanceClass` – The name of the DB instance class to use for your primary instance.
- `DBInstanceIdentifier` – The name of your primary instance.

- Engine=aurora-postgresql – The name of the engine to use.

For more information, see [CreateDBInstance](#) in the *Amazon RDS API Reference*.

## Promoting an Aurora read replica

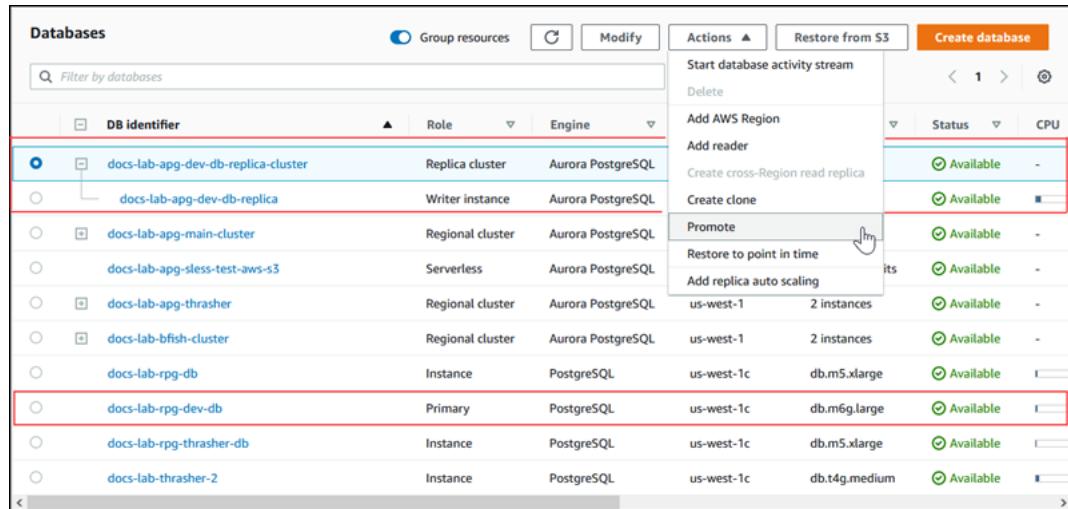

The migration to Aurora PostgreSQL isn't complete until you promote the Replica cluster, so don't delete the RDS for PostgreSQL source DB instance just yet.

Before promoting the Replica cluster, make sure that the RDS for PostgreSQL DB instance doesn't have any in-process transactions or other activity writing to the database. When the replica lag on the Aurora read replica reaches zero (0), you can promote the Replica cluster. For more information about monitoring replica lag, see [Monitoring Aurora PostgreSQL replication \(p. 1224\)](#) and [Instance-level metrics for Amazon Aurora \(p. 531\)](#).

### Console

#### To promote an Aurora read replica to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Replica cluster.

4. For **Actions**, choose **Promote**. This may take a few minutes.

When the process completes, the Aurora Replica cluster is a Regional Aurora PostgreSQL DB cluster, with a Writer instance containing the data from the RDS for PostgreSQL DB instance.

### AWS CLI

To promote an Aurora read replica to a stand-alone DB cluster, use the [promote-read-replica-db-cluster](#) AWS CLI command.

### Example

For Linux, macOS, or Unix:

```
aws rds promote-read-replica-db-cluster \
```

```
--db-cluster-identifier myreadreplicacluster
```

For Windows:

```
aws rds promote-read-replica-db-cluster ^
--db-cluster-identifier myreadreplicacluster
```

## RDS API

To promote an Aurora read replica to a stand-alone DB cluster, use the RDS API operation [PromoteReadReplicaDBCluster](#).

After you promote the Replica cluster, you can confirm that the promotion has completed by checking the event log, as follows.

### To confirm that the Aurora Replica cluster was promoted

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Events**.
3. On the **Events** page, find the name of your cluster in the **Source** list. Each event has a source, type, time, and message. You can see all events that have occurred in your AWS Region for your account. A successful promotion generates the following message.

```
Promoted Read Replica cluster to a stand-alone database cluster.
```

After promotion is complete, the source RDS for PostgreSQL DB instance and the Aurora PostgreSQL DB cluster are unlinked. You can direct your client applications to the endpoint for the Aurora read replica. For more information on the Aurora endpoints, see [Amazon Aurora connection management \(p. 35\)](#). At this point, you can safely delete the DB instance.

# Using Babelfish for Aurora PostgreSQL

Babelfish for Aurora PostgreSQL extends your Aurora PostgreSQL DB cluster with the ability to accept database connections from SQL Server clients. With Babelfish, applications that were originally built for SQL Server can work directly with Aurora PostgreSQL with few code changes compared to a traditional migration and without changing database drivers. For more information about migrating, see [Migrating a SQL Server database to Babelfish for Aurora PostgreSQL \(p. 1093\)](#).

**Note**

Babelfish for Aurora PostgreSQL is available with Aurora PostgreSQL 13.4 and higher versions.

Babelfish provides an additional endpoint for an Aurora PostgreSQL database cluster that allows it to understand the SQL Server wire-level protocol and commonly used SQL Server statements. Client applications that use the Tabular Data Stream (TDS) wire protocol can connect natively to the TDS listener port on Aurora PostgreSQL. To learn more about TDS, see [\[MS-TDS\]: Tabular Data Stream Protocol](#) on the Microsoft website.

**Note**

Babelfish for Aurora PostgreSQL supports TDS versions 7.1 through 7.4.

Babelfish also provides access to data using the native PostgreSQL connection. By default, both SQL dialects supported by Babelfish are available through their native wire protocols at the following ports:

- SQL Server dialect (T-SQL), clients connect to port 1433.
- PostgreSQL dialect (PL/pgSQL), clients connect to port 5432.

Babelfish runs the Transact-SQL (T-SQL) language with some differences. For more information, see [Differences between Babelfish for Aurora PostgreSQL and SQL Server \(p. 1108\)](#).

In the following sections, you can find information about setting up and using a Babelfish for Aurora PostgreSQL DB cluster.

## Topics

- [Understanding Babelfish architecture and configuration \(p. 1064\)](#)
- [Creating a Babelfish for Aurora PostgreSQL DB cluster \(p. 1086\)](#)
- [Migrating a SQL Server database to Babelfish for Aurora PostgreSQL \(p. 1093\)](#)
- [Connecting to a Babelfish DB cluster \(p. 1097\)](#)
- [Working with Babelfish \(p. 1106\)](#)
- [Troubleshooting Babelfish \(p. 1123\)](#)
- [Turning off Babelfish \(p. 1125\)](#)
- [Babelfish version updates \(p. 1126\)](#)
- [Babelfish for Aurora PostgreSQL reference \(p. 1128\)](#)

# Understanding Babelfish architecture and configuration

You manage the Aurora PostgreSQL-Compatible Edition DB cluster running Babelfish much as you would any Aurora DB cluster. That is, you benefit from the scalability, high-availability with failover support, and built-in replication provided by an Aurora DB cluster. To learn more about these capabilities, see [Managing performance and scaling for Aurora DB clusters \(p. 274\)](#), [High availability for Amazon Aurora \(p. 71\)](#), and [Replication with Amazon Aurora \(p. 73\)](#). You also have access to many other AWS tools and utilities, including the following:

- Amazon CloudWatch is a monitoring and observability service that provides you with data and actionable insights. For more information, see [Monitoring Amazon Aurora metrics with Amazon CloudWatch \(p. 452\)](#).
- Performance Insights is a database performance tuning and monitoring feature that helps you quickly assess the load on your database. To learn more, see [Monitoring DB load with Performance Insights on Amazon Aurora \(p. 461\)](#).
- Aurora global databases span multiple AWS Regions, enabling low latency global reads and providing fast recovery from the rare outage that might affect an entire AWS Region. For more information, see [Using Amazon Aurora global databases \(p. 151\)](#).
- Automatic software patching keeps your database up-to-date with the latest security and feature patches when they become available.
- Amazon RDS events notify you by email or SMS message of important database events, such as an automated failover. For more information, see [Monitoring Amazon Aurora events \(p. 568\)](#).

However, not all Aurora features are supported. Currently, Babelfish doesn't support the following:

- AWS Directory Service
- AWS Identity and Access Management
- Database activity streams (DAS)
- Kerberos
- Query plan management (QPM)
- SCRAM (salted challenge response authentication mechanism)
- Zero-downtime patching (ZDP)

Currently, Babelfish isn't a HIPAA eligible service listed in the AWS [HIPAA Eligible Services Reference](#). To learn more, see [Amazon Aurora PostgreSQL in Architecting for HIPAA Security and Compliance on Amazon Web Services](#).

Following, you can learn about Babelfish architecture and how the SQL Server databases that you migrate are handled by Babelfish. When you create your Babelfish DB cluster, you need to make some decisions up front about single database or multiple databases, collations, and other details.

## Topics

- [Babelfish architecture \(p. 1065\)](#)
- [DB cluster parameter group settings for Babelfish \(p. 1068\)](#)
- [Collations supported by Babelfish \(p. 1073\)](#)
- [Managing Babelfish error handling with escape hatches \(p. 1081\)](#)

## Babelfish architecture

When you create an Aurora PostgreSQL cluster with Babelfish turned on, Aurora provisions the cluster with a PostgreSQL database named `babelfish_db`. This database is where all migrated SQL Server objects and structures reside.

### Note

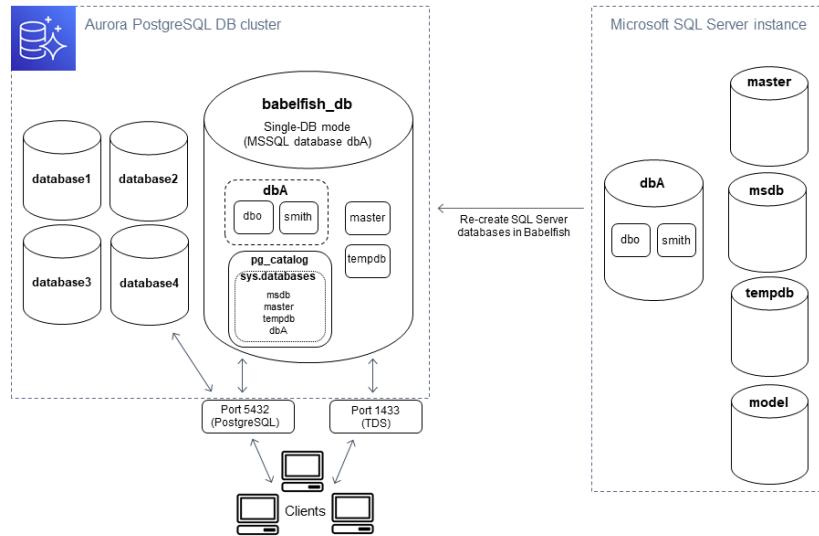

In an Aurora PostgreSQL cluster, the `babelfish_db` database name is reserved for Babelfish. Creating your own "babelfish\_db" database on a Babelfish DB cluster prevents Aurora from successfully provisioning Babelfish.

When you connect to the TDS port, the session is placed in the `babelfish_db` database. From T-SQL, the structure looks similar to being connected to a SQL Server instance. You can see the `master`, `msdb`, and `tempdb` databases, and the `sys.databases` catalog. You can create additional user databases and switch between databases with the `USE` statement. When you create a SQL Server user database, it's flattened into the `babelfish_db` PostgreSQL database. Your database retains cross-database syntax and semantics equal to or similar to those provided by SQL Server.

## Using Babelfish with a single database or multiple databases

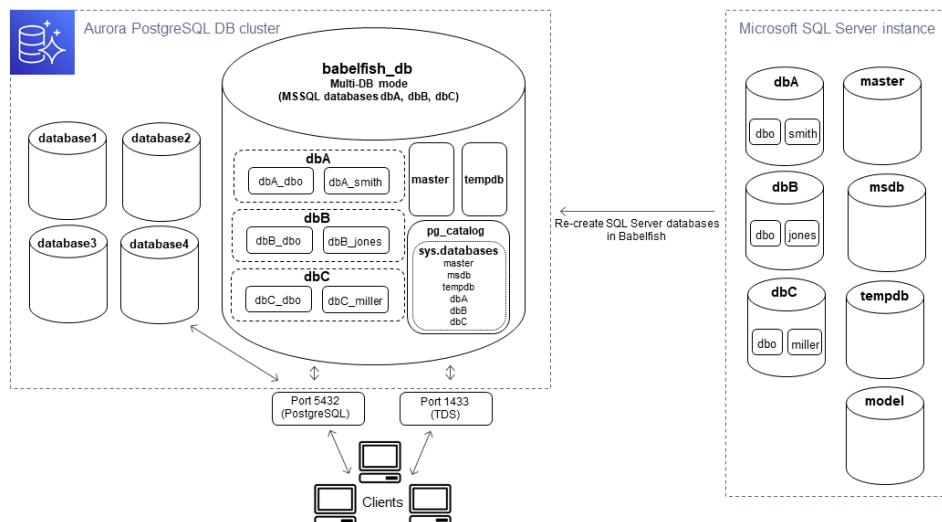

When you create an Aurora PostgreSQL cluster to use with Babelfish, you choose between using a single SQL Server database on its own or multiple SQL Server databases together. Your choice affects how the names of SQL Server schemas inside the `babelfish_db` database appear from Aurora PostgreSQL. The migration mode is stored in the `migration_mode` parameter. You can't change this parameter after creating your cluster.

In single-database mode, the schema names of the user database in the `babelfish_db` database remain the same as in SQL Server. If you choose to move a single database, schemas are recreated inside of the database and can be referenced with the same name used with SQL Server. For example, the `dbo` and `smith` schemas reside inside the `dbA` database.

When connecting through TDS, you can run `USE dbA` to see schemas `dbo` and `smith` from T-SQL, as you would in SQL Server. The unchanged schema names are also visible from PostgreSQL.

In multiple-database mode, the schema names of user databases become `dbname_schemaname` when seen from PostgreSQL. The schema names remain the same when seen from T-SQL.

As shown in the image, multiple-database mode and single-database mode are the same as SQL Server when connecting through the TDS port and using T-SQL. For example, `USE dbA` lists schemas `dbo` and `smith` just as it does in SQL Server. The mapped schema names, such as `dbA_dbo` and `dbA_smith`, are visible from PostgreSQL.

Each database still contains your schemas. The name of each database is prepended to the name of the SQL Server schema, using an underscore as a delimiter, for example:

- dbA contains dbA\_dbo and dbA\_smith.
- dbB contains dbB\_dbo and dbB\_jones.
- dbC contains dbC\_dbo and dbC\_miller.

Inside the `babelfish_db` database, the T-SQL user still needs to run `USE dbname` to change database context, so the look and feel remains similar to SQL Server.

## Choosing a migration mode

Each migration mode has advantages and disadvantages. Choose your migration mode based on the number of user databases you have, and your migration plans. After you create a cluster for use with Babelfish, you can't change the migration mode. When choosing a migration mode, consider the requirements of your user databases and clients.

When you create a cluster for use with Babelfish, Aurora PostgreSQL creates the system databases, `master` and `tempdb`. If you created or modified objects in the system databases (`master` or `tempdb`), make sure to recreate those objects in your new cluster. Unlike SQL Server, Babelfish doesn't reinitialize `tempdb` after a cluster reboot.

Use single database migration mode in the following cases:

- If you are migrating a single SQL Server database. In single database mode, migrated schema names are identical to the original SQL Server schema names. When you migrate your application, you make fewer changes to your SQL code.

- If your end goal is a complete migration to native Aurora PostgreSQL. Before migrating, consolidate your schemas into a single schema (dbo) and then migrate into a single cluster to lessen required changes.

Use multiple database migration mode in the following cases:

- If you are trying out Babelfish and you aren't sure of your future needs.
- If multiple user databases need to be migrated together, and the end goal isn't to perform a fully native PostgreSQL migration.
- If you might be migrating multiple databases in the future.

## DB cluster parameter group settings for Babelfish

When you create an Aurora PostgreSQL DB cluster and choose **Turn on Babelfish**, a DB cluster parameter group is created for you automatically if you choose **Create new**. This DB cluster parameter group is based on the Aurora PostgreSQL DB cluster parameter group for the Aurora PostgreSQL version chosen for the install, for example, Aurora PostgreSQL version 14. It's named using the following general pattern:

custom-aurora-postgresql14-babelfish-compat-3

You can change the following settings during the cluster creation process but some of these can't be changed once they're stored in the custom parameter group, so choose carefully:

- Single database or Multiple databases
- Default collation locale
- Collation name
- Babelfish TDS port
- DB parameter group

To use an existing Aurora PostgreSQL DB cluster version 13 or higher parameter group, edit the group and set the `babelfish_status` parameter to `on`. Specify any Babelfish options before creating your Aurora PostgreSQL cluster. To learn more, see [Working with parameter groups \(p. 215\)](#).

The following parameters control Babelfish preferences. Unless otherwise stated in the Description, parameters are modifiable. The default value is included in the description. To see the allowable values for any parameter, do as follows:

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Parameter groups** from the navigation menu.
3. Choose the `default.aurora-postgresql14` DB cluster parameter group from the list.
4. Enter the name of a parameter in the search field. For example, enter `babelfishpg_tsql.default_locale` in the search field to display this parameter and its default value and allowable settings.

Parameter	Description
<code>babelfishpg_tds.tds_default_numeric_scale</code>	Sets the default scale of numeric type to be sent in the TDS column metadata if the engine doesn't specify one. (Default: 8) (Allowable: 0–38)
<code>babelfishpg_tds.tds_default_numeric_precision</code>	An integer that sets the default precision of numeric type to be sent in the TDS column metadata if the engine doesn't specify one. (Default: 38) (Allowable: 1–38)
<code>babelfishpg_tds.tds_default_packet_size</code>	An integer that sets the default packet size for connecting SQL Server clients. (Default: 4096) (Allowable: 512–32767)
<code>babelfishpg_tds.tds_default_protocol_version</code>	An integer that sets a default TDS protocol version for connecting clients. (Default: DEFAULT) (Allowable: TDSv7.0, TDSv7.1, TDSv7.1.1, TDSv7.2, TDSv7.3A, TDSv7.3B, TDSv7.4, DEFAULT)

Parameter	Description
babelfishpg_tds.default_server_name	A string that identifies the default name of the Babelfish server. (Default: Microsoft SQL Server) (Allowable: null)
babelfishpg_tds.enable_tds_debug_log_level	An integer that sets the logging level in TDS; 0 turns off logging. (Default: 1) (Allowable: 0, 1, 2, 3)
babelfishpg_tds.listen_addresses	A string that sets the host name or IP address or addresses to listen for TDS on. This parameter can't be modified after the Babelfish DB cluster is created. (Default: * ) (Allowable: null)
babelfishpg_tds.port	An integer that specifies the TCP port used for requests in SQL Server syntax. (Default: 1433) (Allowable: 1–65535)
babelfishpg_tds.tds_ssl_encrypt	A boolean that turns encryption on (0) or off (1) for data traversing the TDS listener port. For detailed information about using SSL for client connections, see <a href="#">Babelfish SSL settings and client connections (p. 1071)</a> . (Default: 0) (Allowable: 0, 1)
babelfishpg_tds.tds_ssl_max_protocol_version	A string that specifies the highest SSL/TLS protocol version to use for the TDS session. (Default: 'TLSv1.2') (Allowable: 'TLSv1', 'TLSv1.1', 'TLSv1.2')
babelfishpg_tds.tds_ssl_min_protocol_version	A string that specifies the minimum SSL/TLS protocol version to use for the TDS session. (Default: 'TLSv1') (Allowable: 'TLSv1', 'TLSv1.1', 'TLSv1.2')
babelfishpg_tds.unix_socket_directories	A string that identifies the TDS server Unix socket directory. This parameter can't be modified after the Babelfish DB cluster is created. (Default: /tmp) (Allowable: null)
babelfishpg_tds.unix_socket_group	A string that identifies the TDS server Unix socket group. This parameter can't be modified after the Babelfish DB cluster is created. (Default: rdsdb) (Allowable: null)
babelfishpg_tsql.default_locale	A string that specifies the default locale used for Babelfish collations. The default locale is the locale only and doesn't include any qualifiers.  Set this parameter when you provision a Babelfish DB cluster. After the DB cluster is provisioned, changes to this parameter are ignored. (Default: en_US) (Allowable: See <a href="#">tables (p. 1073)</a> )
babelfishpg_tsql.migration_mode	A non-modifiable list that specifies support for single- or multiple user databases. Set this parameter when you provision a Babelfish DB cluster. After the DB cluster is provisioned, you can't modify this parameter's value. (Default: single-db) (Allowable: single-db, multi-db,null)

Parameter	Description
<code>babelfishpg_tsql.server_collation_name</code>	A string that specifies the name of the collation used for server-level actions. Set this parameter when you provision a Babelfish DB cluster. After the DB cluster is provisioned, don't modify the value of this parameter. (Default: <code>bbf_unicode_general_ci_as</code> ) (Allowable: See <a href="#">tables (p. 1073)</a> )
<code>babelfishpg_tsql.version</code>	A string that sets the output of <code>@@VERSION</code> variable. Don't modify this value for Aurora PostgreSQL DB clusters. (Default: <code>null</code> ) (Allowable: default)
<code>rds.babelfish_status</code>	A string that sets the state of Babelfish functionality. When this parameter is set to <code>datatypesonly</code> , Babelfish is turned off but SQL Server data types are still available. (Default: <code>off</code> ) (Allowable: <code>on</code> , <code>off</code> , <code>datatypesonly</code> )
<code>unix_socket_permissions</code>	An integer that sets the TDS server Unix socket permissions. This parameter can't be modified after the Babelfish DB cluster is created. (Default: <code>0700</code> ) (Allowable: <code>0–511</code> )

## Babelfish SSL settings and client connections

When a client connects to the TDS port (default 1433), Babelfish compares the Secure Sockets Layer (SSL) setting sent during the client handshake to the Babelfish SSL parameter setting (`tds_ssl_encrypt`). Babelfish then determines if a connection is allowed. If a connection is allowed, encryption behavior is either enforced or not, depending on your parameter settings and the support for encryption offered by the client.

The table following shows how Babelfish behaves for each combination.

Client SSL setting	Babelfish SSL setting	Connection allowed?	Value returned to client
ENCRYPT_OFF	<code>tds_ssl_encrypt=false</code>	Allowed, the login packet is encrypted	ENCRYPT_OFF
ENCRYPT_OFF	<code>tds_ssl_encrypt=true</code>	Allowed, the entire connection is encrypted	ENCRYPT_REQ
ENCRYPT_ON	<code>tds_ssl_encrypt=false</code>	Allowed, the entire connection is encrypted	ENCRYPT_ON
ENCRYPT_ON	<code>tds_ssl_encrypt=true</code>	Allowed, the entire connection is encrypted	ENCRYPT_ON
ENCRYPT_NOT_SUP	<code>tds_ssl_encrypt=false</code>	Yes	ENCRYPT_NOT_SUP
ENCRYPT_NOT_SUP	<code>tds_ssl_encrypt=true</code>	No, connection closed	ENCRYPT_REQ
ENCRYPT_REQ	<code>tds_ssl_encrypt=false</code>	Allowed, the entire connection is encrypted	ENCRYPT_ON
ENCRYPT_REQ	<code>tds_ssl_encrypt=true</code>	Allowed, the entire connection is encrypted	ENCRYPT_ON
ENCRYPT_CLIENT_CERT	<code>tds_ssl_encrypt=false</code>	No, connection closed	Unsupported
ENCRYPT_CLIENT_CERT	<code>tds_ssl_encrypt=true</code>	No, connection closed	Unsupported

## Client authentication to Babelfish

Babelfish for Aurora PostgreSQL supports password authentication. Passwords are stored in encrypted form on disk. For more information about authentication on an Aurora PostgreSQL cluster, see [Security with Amazon Aurora PostgreSQL \(p. 1018\)](#).

You might be prompted for credentials each time you connect to Babelfish. Any user migrated to or created on Aurora PostgreSQL can use the same credentials on both the SQL Server port and the PostgreSQL port. Babelfish doesn't enforce password policies, but we recommend that you do the following:

- Require a complex password that's at least eight (8) characters long.
- Enforce a password expiration policy.

To review a complete list of database users, use the command `SELECT * FROM pg_user;`.

## Collations supported by Babelfish

When you create an Aurora PostgreSQL DB cluster with Babelfish, you choose a collation for your data. A *collation* specifies the sort order and bit patterns that produce the text or characters in a given written human language. A collation includes rules comparing data for a given set of bit patterns. Collation is related to localization. Different locales affect character mapping, sort order, and the like. Collation attributes are reflected in the names of various collations. For information about attributes, see the [Babelfish collation attributes table](#).

Babelfish maps SQL Server collations to comparable collations provided by Babelfish. Babelfish predefines Unicode collations with culturally sensitive string comparisons and sort orders. Babelfish also provides a way to translate the collations in your SQL Server DB to the closest-matching Babelfish collation. Locale-specific collations are provided for different languages and regions.

Some collations specify a code page that corresponds to a client-side encoding. Babelfish automatically translates from the server encoding to the client encoding depending on the collation of each output column.

Babelfish supports the collations listed in the [Babelfish supported collations table](#). Babelfish maps SQL Server collations to comparable collations provided by Babelfish.

Babelfish uses version 153.80 of the International Components for Unicode (ICU) collation library. For more information about ICU collations, see [Collation](#) in the ICU documentation. To learn more about PostgreSQL and collation, see [Collation Support](#) in the the PostgreSQL documentation.

## DB cluster parameters that control collation and locale

The following parameters affect collation behavior.

### **`babelfishpg_tsql.default_locale`**

This parameter specifies the default locale used by the collation. This parameter is used in combination with attributes listed in the [Babelfish collation attributes table](#) to customize collations for a specific language and region. The default value for this parameter is `en-US`.

The default locale applies to all Babelfish collation names that start with "BBF" and to all SQL Server collations that are mapped to Babelfish collations. Changing the setting for this parameter on an existing Babelfish DB cluster doesn't affect the locale of existing collations. For the list of collations, see the [Babelfish supported collations table](#).

### **`babelfishpg_tsql.server_collation_name`**

This parameter specifies the default collation for the server (Aurora PostgreSQL DB cluster instance) and the database. The default value is `sql_latin1_general_cp1_ci_as`. The `server_collation_name` has to be a `CI_AS` collation because in T-SQL, the server collation determines how identifiers are compared.

When you create your Babelfish DB cluster, you choose the **Collation name** from the selectable list. These include the collations listed in the [Babelfish supported collations table](#). Don't modify the `server_collation_name` after the Babelfish database is created.

The settings you choose when you create your Babelfish for Aurora PostgreSQL DB cluster are stored in the DB cluster parameter group associated with the cluster for these parameters and set its collation behavior.

## Deterministic and nondeterministic collations and Babelfish

Babelfish supports deterministic and nondeterministic collations:

- A *deterministic collation* evaluates characters that have identical byte sequences as equal. That means that `x` and `X` aren't equal in a deterministic collation. Deterministic collations can be case-sensitive (CS) and accent-sensitive (AS).
- A *nondeterministic collation* doesn't need an identical match. A nondeterministic collation evaluates `x` and `X` as equal. Nondeterministic collations are case-insensitive (CI) and accent-insensitive (AI).

In the table following, you can find some behavior differences between Babelfish and PostgreSQL when using nondeterministic collations.

Babelfish	PostgreSQL
Supports the LIKE clause for CI_AS collations.	Doesn't support the LIKE clause on nondeterministic collations.
Doesn't support the LIKE clause on AI collations.	
Don't support pattern-matching operations on nondeterministic collations.	

For a list of other limitations and behavior differences for Babelfish compared to SQL Server and PostgreSQL, see [Collation limitations and behavior differences \(p. 1078\)](#).

Babelfish and SQL Server follow a naming convention for collations that describe the collation attributes, as shown in the table following.

Attribute	Description
AI	Accent-insensitive.
AS	Accent-sensitive.
BIN2	BIN2 requests data to be sorted in code point order. Unicode code point order is the same character order for UTF-8, UTF-16, and UCS-2 encodings. Code point order is a fast deterministic collation.
CI	Case-insensitive.
CS	Case-sensitive.
PREF	To sort uppercase letters before lowercase letters, use a PREF collation. If comparison is case-insensitive, the uppercase version of a letter sorts before the lowercase version, if there is no other distinction. The ICU library supports uppercase preference with <code>colCaseFirst=upper</code> , but not for CI_AS collations.  PREF can be applied only to CS_AS deterministic collations.

## Collations supported by Babelfish

Use the following collations as a server collation or an object collation.

Collation ID	Notes
bbf_unicode_general_ci_as	Supports case-insensitive comparison and the LIKE operator.
bbf_unicode_cp1_ci_as	<a href="#">Nondeterministic collation</a> also known as CP1252.
bbf_unicode_CP1250_ci_as	<a href="#">Nondeterministic collation</a> used to represent texts in Central European and Eastern European languages that use Latin script.
bbf_unicode_CP1251_ci_as	<a href="#">Nondeterministic collation</a> for languages that use the Cyrillic script.
bbf_unicode_cp1253_ci_as	<a href="#">Nondeterministic collation</a> used to represent modern Greek.
bbf_unicode_cp1254_ci_as	<a href="#">Nondeterministic collation</a> that supports Turkish.
bbf_unicode_cp1255_ci_as	<a href="#">Nondeterministic collation</a> that supports Hebrew.
bbf_unicode_cp1256_ci_as	<a href="#">Nondeterministic collation</a> used to write languages that use Arabic script.
bbf_unicode_cp1257_ci_as	<a href="#">Nondeterministic collation</a> used to support Estonian, Latvian, and Lithuanian languages.
bbf_unicode_cp1258_ci_as	<a href="#">Nondeterministic collation</a> used to write Vietnamese characters.
bbf_unicode_cp874_ci_as	<a href="#">Nondeterministic collation</a> used to write Thai characters.
sql_latin1_general_cp1250_ci_as	<a href="#">Nondeterministic single-byte character encoding</a> used to represent Latin characters.
sql_latin1_general_cp1251_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1253_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1254_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1255_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1256_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1257_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1258_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
chinese_prc_ci_as	Nondeterministic collation that supports Chinese (PRC).
cyrillic_general_ci_as	Nondeterministic collation that supports Cyrillic.
finnish_swedish_ci_as	Nondeterministic collation that supports Finnish.
french_ci_as	Nondeterministic collation that supports French.
japanese_ci_as	Nondeterministic collation that supports Japanese. Supported in Babelfish 2.1.0 and higher releases.
korean_wansung_ci_as	Nondeterministic collation that supports Korean (with dictionary sort).
latin1_general_ci_as	Nondeterministic collation that supports Latin characters.

<b>Collation ID</b>	<b>Notes</b>
modern_spanish_ci_as	Nondeterministic collation that supports Modern Spanish.
polish_ci_as	Nondeterministic collation that supports Polish.
thai_ci_as	Nondeterministic collation that supports Thai.
traditional_spanish_ci_as	Nondeterministic collation that supports Spanish (traditional sort).
turkish_ci_as	Nondeterministic collation that supports Turkish.
ukrainian_ci_as	Nondeterministic collation that supports Ukrainian.
vietnamese_ci_as	Nondeterministic collation that supports Vietnamese.

You can use the following collations as object collations.

<b>Dialect</b>	<b>Deterministic options</b>	<b>Nondeterministic options</b>
Arabic	Arabic_CS_AS	Arabic_CI_AS, Arabic_CI_AI
Chinese	Chinese_CS_AS	Chinese_CI_AS, Chinese_CI_AI
Cyrillic_General	Cyrillic_General_CS_AS	Cyrillic_General_CI_AS, Cyrillic_General_CI_AI
Estonian	Estonian_CS_AS	Estonian_CI_AS, Estonian_CI_AI
Finnish_Swedish	Finnish_Swedish_CS_AS	Finnish_Swedish_CI_AS, Finnish_Swedish_CI_AI
French	French_CS_AS	French_CI_AS, French_CI_AI
Greek	Greek_CS_AS	Greek_CI_AS, Greek_CI_AI
Hebrew	Hebrew_CS_AS	Hebrew_CI_AS, Hebrew_CI_AI
Japanese (Babelfish 2.1.0 and higher)	Japanese_CS_AS	Japanese_CI_AI, Japanese_CI_AS
Korean_Wamsung	Korean_Wamsung_CS_AS	Korean_Wamsung_CI_AS, Korean_Wamsung_CI_AI
Modern_Spanish	Modern_Spanish_CS_AS	Modern_Spanish_CI_AS, Modern_Spanish_CI_AI
Mongolian	Mongolian_CS_AS	Mongolian_CI_AS, Mongolian_CI_AI
Polish	Polish_CS_AS	Polish_CI_AS, Polish_CI_AI
Thai	Thai_CS_AS	Thai_CI_AS, Thai_CI_AI
Traditional_Spanish	Traditional_Spanish_CS_AS	Traditional_Spanish_CI_AS, Traditional_Spanish_CI_AI
Turkish	Turkish_CS_AS	Turkish_CI_AS, Turkish_CI_AI
Ukrainian	Ukrainian_CS_AS	Ukrainian_CI_AS, Ukrainian_CI_AI

Dialect	Deterministic options	Nondeterministic options
Vietnamese	Vietnamese_CS_AS	Vietnamese_CI_AS, Vietnamese_CI_AI

## Managing collations

The ICU library provides collation version tracking to ensure that indexes that depend on collations can be reindexed when a new version of ICU becomes available. To see if your current database has collations that need refreshing, you can use the following query after connecting using `psql` or `pgAdmin`:

```
SELECT pg_describe_object(refclassid, refobjid,
    refobjsubid) AS "Collation",
    pg_describe_object(classid, objid, objsubid) AS "Object"
FROM pg_depend d JOIN pg_collation c ON refclassid = 'pg_collation'::regclass
AND refobjid = c.oid WHERE c.colversion <> pg_collation_actual_version(c.oid)
ORDER BY 1, 2;
```

This query returns output such as the following:

Collation   Object
(0 rows)

In this example, no collations need to be updated.

To get a listing of the predefined collations in your Babelfish database, you can use `psql` or `pgAdmin` with the following query:

```
SELECT * FROM pg_collation;
```

Predefined collations are stored in the `sys.fn_helpcollations` table. You can use the following command to display information about a collation (such as its lcid, style, and collate flags). To get a listing of all collations by using `sqlcmd`, connect to the T-SQL port (1433, by default) and run the following query:

```
1> :setvar SQLCMDMAXVARTYPEWIDTH 40
2> :setvar SQLCMDMAXFIXEDTYPEWIDTH 40
3> SELECT * FROM fn_helpcollations()
4> GO
name                                description
-----                                -----
arabic_cs_as                          Arabic, case-sensitive, accent-sensitive
arabic_ci_ai                          Arabic, case-insensitive, accent-insensi
arabic_ci_as                          Arabic, case-insensitive, accent-sensiti
bbf_unicode_bin2                      Unicode-General, case-sensitive, accent-
bbf_unicode_cp1250_ci_ai              Default locale, code page 1250, case-ins
bbf_unicode_cp1250_ci_as              Default locale, code page 1250, case-ins
bbf_unicode_cp1250_cs_ai              Default locale, code page 1250, case-sen
bbf_unicode_cp1250_cs_as              Default locale, code page 1250, case-sen
bbf_unicode_pref_cp1250_cs_as        Default locale, code page 1250, case-sen
bbf_unicode_cp1251_ci_ai              Default locale, code page 1251, case-ins
bbf_unicode_cp1251_ci_as              Default locale, code page 1251, case-ins
bbf_unicode_cp1254_ci_ai              Default locale, code page 1254, case-ins
...
(124 rows affected)
```

Lines 1 and 2 shown in the example narrow the output for documentation readability purposes only.

```

1> SELECT SERVERPROPERTY('COLLATION')
2> GO
serverproperty
-----
sql_latin1_general_cp1_ci_as

(1 rows affected)
1>

```

## Collation limitations and behavior differences

Babelfish uses the ICU library for collation support. PostgreSQL is built with a specific version of ICU and can match at most one version of a collation. Variations across versions are unavoidable, as are minor variations across time as languages evolve. In the following list you can find known limitations and behavior variations of Babelfish collations:

- **Indexes and collation type dependency** – An index on a user-defined type that depends on the International Components for Unicode (ICU) collation library (the library used by Babelfish) isn't invalidated when the library version changes.
- **COLLATIONPROPERTY function** – Collation properties are implemented only for the supported Babelfish BBF collations. For more information, see the [Babelfish supported collations table](#).
- **Unicode sorting rule differences** – SQL collations for SQL Server sort Unicode-encoded data (`nchar` and `nvarchar`) differently than data that's not Unicode-encoded (`char` and `varchar`). Babelfish databases are always UTF-8 encoded and always apply Unicode sorting rules consistently, regardless of data type, so the sort order for `char` or `varchar` is the same as it is for `nchar` or `nvarchar`.
- **Secondary-equal collations and sorting behavior** – The default ICU Unicode secondary-equal (`CI_AS`) collation sorts punctuation marks and other nonalphanumeric characters before numeric characters, and numeric characters before alphabetic characters. However, the order of punctuation and other special characters is different.
- **Tertiary collations, workaround for ORDER BY** – SQL collations, such as `SQL_Latin1_General_Pref_CP1_CI_AS`, support the `TERTIARY_WEIGHTS` function and the ability to sort strings that compare equally in a `CI_AS` collation to be sorted uppercase first: ABC, ABC, AbC, Abc, aBC, aBc, abC, and finally abc. Thus, the `DENSE_RANK OVER (ORDER BY column)` analytic function assesses these strings as having the same rank but orders them uppercase first within a partition.

You can get a similar result with Babelfish by adding a `COLLATE` clause to the `ORDER BY` clause that specifies a tertiary `CS_AS` collation that specifies `@colCaseFirst=upper`. However, the `colCaseFirst` modifier applies only to strings that are tertiary-equal (rather than secondary-equal such as with `CI_AS` collation). Thus, you can't emulate tertiary SQL collations using a single ICU collation.

As a workaround, we recommend that you modify applications that use the `SQL_Latin1_General_Pref_CP1_CI_AS` collation to use the `BBF_SQL_Latin1_General_CP1_CI_AS` collation first. Then add `COLLATE BBF_SQL_Latin1_General_Pref_CP1_CS_AS` to any `ORDER BY` clause for this column.

- **Character expansion** – A character expansion treats a single character as equal to a sequence of characters at the primary level. SQL Server's default `CI_AS` collation supports character expansion. ICU collations support character expansion for accent-insensitive collations only.

When character expansion is required, then use a `AI` collation for comparisons. However, such collations aren't currently supported by the `LIKE` operator.

- **char and varchar encoding** – When SQL collations are used for `char` or `varchar` data types, the sort order for characters preceding ASCII 127 is determined by the specific code page for that SQL collation. For SQL collations, strings declared as `char` or `varchar` might sort differently than strings declared as `nchar` or `nvarchar`.

PostgreSQL encodes all strings with the database encoding, so all characters are converted to UTF-8 and sorted using Unicode rules.

Because SQL collations sort nchar and nvarchar data types using Unicode rules, Babelfish encodes all strings on the server using UTF-8. Babelfish sorts nchar and nvarchar strings the same way it sorts char and varchar strings, using Unicode rules.

- **Supplementary character** – The SQL Server functions `NCHAR`, `UNICODE`, and `LEN` support characters for code-points outside the Unicode Basic Multilingual Plane (BMP). In contrast, non-SC collations use surrogate pair characters to handle supplementary characters. For Unicode data types, SQL Server can represent up to 65,535 characters using UCS-2, or the full Unicode range (1,114,114 characters) if supplementary characters are used.
- **Kana-sensitive (KS) collations** – A Kana-sensitive (KS) collation is one that treats Hiragana and Katakana Japanese Kana characters differently. ICU supports the Japanese collation standard `JIS_X_4061`. The now deprecated `colhiraganaQ [on | off]` locale modifier might provide the same functionality as KS collations. However, KS collations of the same name as SQL Server aren't currently supported by Babelfish.
- **Width-sensitive (WS) collations** – When a single-byte character (half-width) and the same character represented as a double-byte character (full-width) are treated differently, the collation is called *width-sensitive (WS)*. WS collations with the same name as SQL Server aren't currently supported by Babelfish.
- **Variation-selector sensitive (VSS) collations** – Variation-selector sensitive (VSS) collations distinguish between ideographic variation selectors in Japanese collations `Japanese_Bushu_Kakusu_140` and `Japanese_XJIS_140`. A variation sequence is made up of a base character plus an additional variation selector. If you don't select the `_VSS` option, the variation selector isn't considered in the comparison.

VSS collations aren't currently supported by Babelfish.

- **BIN and BIN2 collations** – A BIN2 collation sorts characters according to code point order. The byte-by-byte binary order of UTF-8 preserves Unicode code point order, so this is also likely to be the best-performing collation. If Unicode code point order works for an application, consider using a BIN2 collation. However, using a BIN2 collation can result in data being displayed on the client in an order that is culturally unexpected. New mappings to lowercase characters are added to Unicode as time progresses, so the `LOWER` function might perform differently on different versions of ICU. This is a special case of the more general collation versioning problem rather than as something specific to the BIN2 collation.

Babelfish provides the `BBF_Latin1_General_BIN2` collation with the Babelfish distribution to collate in Unicode code point order. In a BIN collation only the first character is sorted as a wchar. Remaining characters are sorted byte-by-byte, effectively in code point order according to its encoding. This approach doesn't follow Unicode collation rules and isn't supported by Babelfish.

- **Non-deterministic collations and CHARINDEX limitation** – For Babelfish releases older than version 2.1.0, you can't use CHARINDEX with non-deterministic collations. By default, Babelfish uses a case-insensitive (non-deterministic) collation. Using CHARINDEX for older versions of Babelfish raises the following runtime error:

```
nondeterministic collations are not supported for substring searches
```

#### Note

This limitation and workaround apply to Babelfish version 1.x only (Aurora PostgreSQL 13.4 through 13.7). Babelfish 2.1.0 and higher releases don't have this issue.

You can work around this issue in one of the following ways:

- Explicitly convert the expression to a case-sensitive collation and case-fold both arguments by applying LOWER or UPPER. For example, `SELECT charindex('x', a) FROM t1` would become the following:

```
SELECT charindex(LOWER('x'), LOWER(a COLLATE sql_latin1_general_cp1_cs_as)) FROM t1
```

- Create a SQL function `f_charindex`, and replace CHARINDEX calls with calls to the following function:

```
CREATE function f_charindex(@s1 varchar(max), @s2 varchar(max)) RETURNS int
AS
BEGIN
declare @i int = 1
WHILE len(@s2) >= len(@s1)
BEGIN
    if LOWER(@s1) = LOWER(substring(@s2,1,len(@s1))) return @i
    set @i += 1
    set @s2 = substring(@s2,2,999999999)
END
return 0
END
go
```

## Managing Babelfish error handling with escape hatches

Babelfish mimics SQL behavior for control flow and transaction state whenever possible. When Babelfish encounters an error, it returns an error code similar to the SQL Server error code. If Babelfish can't map the error to a SQL Server code, it returns a fixed error code (33557097) and takes specific actions based on the type of error, as follows:

- For compile time errors, Babelfish rolls back the transaction.
- For runtime errors, Babelfish ends the batch and rolls back the transaction.
- For protocol error between client and server, the transaction isn't rolled back.

If an error code can't be mapped to an equivalent code and the code for a similar error is available, the error code is mapped to the alternative code. For example, the behaviors that cause SQL Server codes 8143 and 8144 are both mapped to 8143.

Errors that can't be mapped don't respect a `TRY... CATCH` construct.

You can use `@@ERROR` to return a SQL Server error code, or the `@@PGERROR` function to return a PostgreSQL error code. You can also use the `fn_mapped_system_error_list` function to return a list of mapped error codes. For information about PostgreSQL error codes, see [the PostgreSQL website](#).

### Modifying Babelfish escape hatch settings

To handle statements that might fail, Babelfish defines certain options called escape hatches. An *escape hatch* is an option that specifies Babelfish behavior when it encounters an unsupported feature or syntax.

You can use the `sp_babelfish_configure` stored procedure to control the settings of an escape hatch. Use the script to set the escape hatch to `ignore` or `strict`. If it's set to `strict`, Babelfish returns an error that you need to correct before continuing.

To apply changes to the current session and on the cluster level, include the `server` keyword.

The usage is as follows:

- To list all escape hatches and their status, plus usage information, run `sp_babelfish_configure`.
- To list the named escape hatches and their values, for the current session or cluster-wide, run the command `sp_babelfish_configure 'hatch_name'` where `hatch_name` is the identifier of one or more escape hatches. `hatch_name` can use SQL wildcards, such as '%'.  
  
To make the settings permanent on a cluster-wide level, include the `server` keyword, such as shown in the following:

```
EXECUTE sp_babelfish_configure 'escape_hatch_unique_constraint', 'ignore', 'server'
```

To set them for the current session only, don't use `server`.

- To reset all escape hatches to their default values, run `sp_babelfish_configure 'default'` (Babelfish 1.2.0 and higher).

The string identifying the hatch (or hatches) can include SQL wildcards. For example, the following sets all syntax escape hatches to `ignore` for the Aurora PostgreSQL cluster.

```
EXECUTE sp_babelfish_configure '%', 'ignore', 'server'
```

In the following table you can find descriptions and default values for the Babelfish predefined escape hatches.

<b>Escape hatch</b>	<b>Description</b>	<b>Default</b>
<code>escape_hatch_constraint_name_for_default</code>	Controls Babelfish behavior related to default constraint names.	ignore
<code>escape_hatch_database_misc_options</code>	Controls Babelfish behavior related to the following options on CREATE or ALTER DATABASE: CONTAINMENT, DB_CHAINING, TRUSTWORTHY, PERSISTENT_LOG_BUFFER.	ignore
<code>escape_hatch_for_replication</code>	Controls Babelfish behavior related to the [NOT] FOR REPLICATION clause when creating or altering a table.	strict
<code>escape_hatch_fulltext</code>	Controls Babelfish behavior related to FULLTEXT features, such a DEFAULT_FULLTEXT_LANGUAGE in CREATE/ALTER DATABASE, CREATE FULLTEXT INDEX, or sp_fulltext_database.	strict
<code>escape_hatch_ignore_dup_key</code>	Controls Babelfish behavior related to CREATE/ALTER TABLE and CREATE INDEX. When IGNORE_DUP_KEY=ON, raises an error when set to strict (the default) or ignores the error when set to ignore (Babelfish version 1.2.0 and higher).	strict
<code>escape_hatch_index_clustering</code>	Controls Babelfish behavior related to the CLUSTERED or NONCLUSTERED keywords for indexes and PRIMARY KEY or UNIQUE constraints. When CLUSTERED is ignored, the index or constraint is still created as if NONCLUSTERED was specified.	ignore
<code>escape_hatch_index_columnstore</code>	Controls Babelfish behavior related to the COLUMNSTORE clause. If you specify ignore, Babelfish creates a regular B-tree index.	strict
<code>escape_hatch_join_hints</code>	Controls the behavior of keywords in a JOIN operator: LOOP, HASH, MERGE, REMOTE, REDUCE, REDISTRIBUTE, REPLICATE.	ignore
<code>escape_hatch_language_non_english</code>	Controls Babelfish behavior related to languages other than English for onscreen messages. Babelfish currently supports only us_english	strict

<b>Escape hatch</b>	<b>Description</b>	<b>Default</b>
	for onscreen messages. SET LANGUAGE might use a variable containing the language name, so the actual language being set can only be detected at run time.	
<code>escape_hatch_login_hashed_password</code>	When ignored, suppresses the error for the HASHED keyword for CREATE LOGIN and ALTER LOGIN.	strict
<code>escape_hatch_login_misc_options</code>	When ignored, suppresses the error for other keywords besides HASHED, MUST_CHANGE, OLD_PASSWORD, and UNLOCK for CREATE LOGIN and ALTER LOGIN.	strict
<code>escape_hatch_login_old_password</code>	When ignored, suppresses the error for the OLD_PASSWORD keyword for CREATE LOGIN and ALTER LOGIN.	strict
<code>escape_hatch_login_password_must_change</code>	When ignored, suppresses the error for the MUST_CHANGE keyword for CREATE LOGIN and ALTER LOGIN.	strict
<code>escape_hatch_login_password_unlock</code>	When ignored, suppresses the error for the UNLOCK keyword for CREATE LOGIN and ALTER LOGIN.	strict
<code>escape_hatch_nocheck_add_constraint</code>	Controls Babelfish behavior related to the WITH CHECK or NOCHECK clause for constraints.	strict
<code>escape_hatch_nocheck_existing_constraint</code>	Controls Babelfish behavior related to FOREIGN KEY or CHECK constraints.	strict
<code>escape_hatch_query_hints</code>	Controls Babelfish behavior related to query hints. When this option is set to ignore, the server ignores hints that use the OPTION (...) clause to specify query processing aspects. Examples include SELECT ... OPTION(MERGE JOIN HASH, MAXRECURSION 10)).	ignore
<code>escape_hatch_rowversion</code>	Controls the behavior of the ROWVERSION and TIMESTAMP datatypes. For usage information, see <a href="#">Using Babelfish features with limited implementation (p. 1113)</a> .	strict
<code>escape_hatch_schemabinding_function</code>	Controls Babelfish behavior related to the WITH SCHEMABINDING clause. By default, the WITH SCHEMABINDING clause is ignored when specified with the CREATE or ALTER FUNCTION command.	ignore

<b>Escape hatch</b>	<b>Description</b>	<b>Default</b>
<code>escape_hatch_schemabinding_procedure</code>	Controls Babelfish behavior related to the WITH SCHEMABINDING clause. By default, the WITH SCHEMABINDING clause is ignored when specified with the CREATE or ALTER PROCEDURE command.	ignore
<code>escape_hatch_rowguidcol_column</code>	Controls Babelfish behavior related to the ROWGUIDCOL clause when creating or altering a table.	strict
<code>escape_hatch_schemabinding_trigger</code>	Controls Babelfish behavior related to the WITH SCHEMABINDING clause. By default, the WITH SCHEMABINDING clause is ignored when specified with the CREATE or ALTER TRIGGER command.	ignore
<code>escape_hatch_schemabinding_view</code>	Controls Babelfish behavior related to the WITH SCHEMABINDING clause. By default, the WITH SCHEMABINDING clause is ignored when specified with the CREATE or ALTER VIEW command.	ignore
<code>escape_hatch_session_settings</code>	Controls Babelfish behavior toward unsupported session-level SET statements.	ignore
<code>escape_hatch_storage_on_partition</code>	Controls Babelfish behavior related to the ON partition_scheme column clause when defining partitioning. Babelfish currently doesn't implement partitioning.	strict
<code>escape_hatch_storage_options</code>	Escape hatch on any storage option used in CREATE, ALTER DATABASE, TABLE, INDEX. This includes clauses (LOG) ON, TEXTIMAGE_ON, FILESTREAM_ON that define storage locations (partitions, file groups) for tables, indexes, and constraints, and also for a database. This escape hatch setting applies to all of these clauses (including ON [PRIMARY] and ON "DEFAULT"). The exception is when a partition is specified for a table or index with ON partition_scheme (column).	ignore
<code>escape_hatch_table_hints</code>	Controls the behavior of table hints specified using the WITH (...) clause.	ignore

Escape hatch	Description	Default
escape_hatch_unique_constraint	When set to strict, an obscure semantic difference between SQL Server and PostgreSQL in handling NULL values on indexed columns can raise errors. The semantic difference only emerges in unrealistic use cases, so you can set this escape hatch to 'ignore' to avoid seeing the error.	strict

# Creating a Babelfish for Aurora PostgreSQL DB cluster

Babelfish for Aurora PostgreSQL is supported on Aurora PostgreSQL version 13.4 and higher.

You can use the AWS Management Console or the AWS CLI to create an Aurora PostgreSQL cluster with Babelfish.

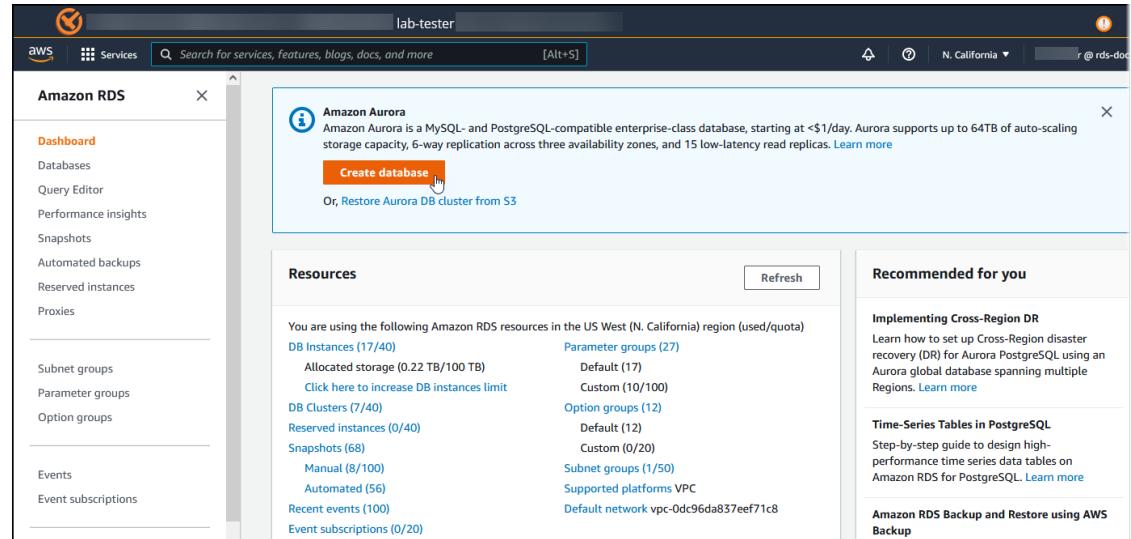

## Note

In an Aurora PostgreSQL cluster, the `babelfish_db` database name is reserved for Babelfish. Creating your own "babelfish\_db" database on a Babelfish for Aurora PostgreSQL prevents Aurora from successfully provisioning Babelfish.

## Console

### To create a cluster with Babelfish running with the AWS Management Console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>, and choose **Create database**.

2. For **Choose a database creation method**, do one of the following:
  - To specify detailed engine options, choose **Standard create**.
  - To use preconfigured options that support best practices for an Aurora cluster, choose **Easy create**.
3. For **Engine type**, choose **Amazon Aurora**.
4. For **Edition**, choose **Amazon Aurora PostgreSQL**.
5. Choose **Show filters**, and then choose **Show versions that support the Babelfish for PostgreSQL feature** to list the engine types that support Babelfish. Babelfish is currently supported on Aurora PostgreSQL 13.4 and higher versions.
6. For **Available versions**, choose an Aurora PostgreSQL version. To get the latest Babelfish features, choose the highest Aurora PostgreSQL major version.

Engine version [Info](#)  
View the engine versions that support the following database features.

▼ Hide filters

Show versions that support the global database feature  
Allows a single Amazon Aurora database to span multiple AWS Regions.

Show versions that support Serverless v2  
Offers instance scaling for even the most demanding workloads.

Show versions that support the Babelfish for PostgreSQL feature  
Makes possible faster, cheaper, and lower-risk migrations from Microsoft SQL Server to Aurora PostgreSQL.

Available versions (3/22) [Info](#)  
Aurora PostgreSQL (Compatible with PostgreSQL 13.6)

7. For **Templates**, choose the template that matches your use case.
8. For **DB cluster identifier**, enter a name that you can easily find later in the DB cluster list.
9. For **Master username**, enter an administrator user name. The default value for Aurora PostgreSQL is `postgres`. You can accept the default or choose a different name. For example, to follow the naming convention used on your SQL Server databases, you can enter `sa` (system administrator) for the Master username.

If you don't create a user named `sa` at this time, you can create one later with your choice of client. After creating the user, use the `ALTER SERVER ROLE` command to add it to the `sysadmin` group (role) for the cluster.
10. For **Master password**, create a strong password and confirm the password.
11. For the options that follow, until the **Babelfish settings** section, specify your DB cluster settings. For information about each setting, see [Settings for Aurora DB clusters \(p. 137\)](#).
12. To make Babelfish functionality available, select the **Turn on Babelfish** box.

**Babelfish settings - new** [Info](#)

Turn on Babelfish  
Makes possible faster, cheaper, and lower-risk migrations from Microsoft SQL Server to Aurora PostgreSQL.

**Babelfish default configurations**  
By default, RDS creates a DB cluster parameter group for you to store the Babelfish settings. Babelfish uses default values if you don't modify these settings in the "Additional configuration" section below.

13. For **DB cluster parameter group**, do one of the following:
  - Choose **Create new** to create a new parameter group with Babelfish turned on.
  - Choose **Choose existing** to use an existing parameter group. If you use an existing group, make sure to modify the group before creating the cluster and add values for Babelfish parameters. For information about Babelfish parameters, see [DB cluster parameter group settings for Babelfish \(p. 1068\)](#).

If you use an existing group, provide the group name in the box that follows.

14. For **Database migration mode**, choose one of the following:

- **Single database** to migrate a single SQL Server database.

In some cases, you might migrate multiple user databases together, with your end goal a complete migration to native Aurora PostgreSQL without Babelfish. If the final applications require consolidated schemas (a single dbo schema), make sure to first consolidate your SQL Server databases into a single SQL server database. Then migrate to Babelfish using **Single database** mode.

- **Multiple databases** to migrate multiple SQL Server databases (originating from a single SQL Server installation). Multiple database mode doesn't consolidate multiple databases that don't originate from a single SQL Server installation. For information about migrating multiple databases, see [Using Babelfish with a single database or multiple databases \(p. 1065\)](#).

## ▼ Additional configuration

Database options, encryption enabled, failover, backup enabled, backtrack disabled, Performance Insights enabled, Enhanced Monitoring enabled, maintenance, CloudWatch Logs, delete protection disabled.

### Database options

#### DB cluster parameter group [Info](#)

Choose a compatible DB Cluster parameter group to turn on Babelfish feature for your database.

Create new

Creates a custom DB cluster parameter group with Babelfish parameters turned on.

Choose existing

Choose an existing DB cluster parameter group with Babelfish parameters turned on.

New custom DB cluster parameter group name

custom-aurora-postgresql13-babelfish-compat-1

### Babelfish configuration

#### Database migration mode [Info](#)

Single database

Use for migrating a single SQL Server database. Migrated schema names are identical between TDS connections and PostgreSQL connections.

Multiple databases

Use for migrating multiple SQL Server databases together. Migrated database and schema names are mapped to similar schema names in PostgreSQL.

15. For **Default collation locale**, enter your server locale. The default is en-US. For detailed information about collations, see [Collations supported by Babelfish \(p. 1073\)](#).
16. For **Collation name** field, enter your default collation. The default is sql\_latin1\_general\_cp1\_ci\_as. For detailed information, see [Collations supported by Babelfish \(p. 1073\)](#).
17. For **Babelfish TDS port**, enter the default port 1433 unless you specified a different port for your Babelfish DB cluster.
18. For **DB parameter group**, choose a parameter group or have Aurora create a new group for you with default settings.
19. For **Failover priority**, choose a failover priority for the instance. If you don't choose a value, the default is tier-1. This priority determines the order in which replicas are promoted when recovering from a primary instance failure. For more information, see [Fault tolerance for an Aurora DB cluster \(p. 72\)](#).

20. For **Backup retention period**, choose the length of time (1–35 days) that Aurora retains backup copies of the database. You can use backup copies for point-in-time restores (PITR) of your database down to the second. The default retention period is seven days.

**Default collation locale** [Info](#)

en-US

**Collation name** [Info](#)

sql\_latin1\_general\_cp1\_ci\_as

**Babelfish TDS port** [Info](#)  
TDS port that the database will use for application connections.

1433

**DB parameter group** [Info](#)

default.aurora-postgresql13

**Option group** [Info](#)

default:aurora-postgresql-13

**Failover priority**

No preference

**Backup**

**Backup retention period** [Info](#)  
Choose the number of days that RDS should retain automatic backups for this instance.

7 days

21. Choose **Copy tags to snapshots** to copy any DB instance tags to a DB snapshot when you create a snapshot.
22. Choose **Enable encryption** to turn on encryption at rest (Aurora storage encryption) for this DB cluster.
23. Choose **Enable Performance Insights** to turn on Amazon RDS Performance Insights.
24. Choose **Enable Enhanced monitoring** to start gathering metrics in real time for the operating system that your DB cluster runs on.
25. Choose **PostgreSQL log** to publish the log files to Amazon CloudWatch Logs.
26. Choose **Enable auto minor version upgrade** to automatically update your Aurora DB cluster when a minor version upgrade is available.
27. For **Maintenance window**, do the following:

- To choose a time for Amazon RDS to make modifications or perform maintenance, choose **Select window**.
  - To perform Amazon RDS maintenance at an unscheduled time, choose **No preference**.
28. Select the **Enable deletion protection** box to protect your database from being deleted by accident.

If you turn on this feature, you can't directly delete the database. Instead, you need to modify the database cluster and turn off this feature before deleting the database.

**Maintenance**

Auto minor version upgrade [Info](#)

**Enable auto minor version upgrade**  
Enabling auto minor version upgrade will automatically upgrade to new minor versions as they are released. The automatic upgrades occur during the maintenance window for the database.

**Maintenance window** [Info](#)  
Select the period you want pending modifications or maintenance applied to the database by Amazon RDS.

**Select window**  
 **No preference**

**Deletion protection**

**Enable deletion protection**  
Protects the database from being deleted accidentally. While this option is enabled, you can't delete the database.

29. Choose **Create database**.

You can find your new database set up for Babelfish in the **Databases** listing. The **Status** column displays **Available** when the deployment is complete.

Databases									<input checked="" type="checkbox"/> Group resources	<a href="#">Modify</a>	<a href="#">Actions</a> ▾	<a href="#">Restore from S3</a>	<a href="#">Create database</a>
<a href="#">Filter databases</a>		DB Identifier	Role	Engine	Region & AZ	Size	Status	CPU	Current activity	Maintenance			
<input type="radio"/>	babelfish-workshop	Regional cluster	Aurora PostgreSQL	us-west-2	1 instance	<span>Available</span>	-	-	-	none			
<input type="radio"/>	babelfish-workshop-instance-1	Writer Instance	Aurora PostgreSQL	-	db.r6g.large	<span>Creating</span>	-	<span>0 Sessions</span>	-	none			

## AWS CLI

When you create an Babelfish for Aurora PostgreSQL; using the AWS CLI, you need to pass the command the name of the DB cluster parameter group to use for the cluster. For more information, see [DB cluster prerequisites \(p. 127\)](#).

Before you can use the AWS CLI to create an Aurora PostgreSQL cluster with Babelfish, do the following:

- Choose your endpoint URL from the list of services at [Amazon Aurora endpoints and quotas](#).
- Create a parameter group for the cluster. For more information about parameter groups, see [Working with parameter groups \(p. 215\)](#).
- Modify the parameter group, adding the parameter that turns on Babelfish.

## To create an Aurora PostgreSQL DB cluster with Babelfish using the AWS CLI

The examples that follow use the default Master username, `postgres`. Replace as needed with the username that you created for your DB cluster, such as `sa` or whatever username you chose if you didn't accept the default.

1. Create a parameter group.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-parameter-group \
--endpoint-url endpoint-url \
--db-cluster-parameter-group-name parameter-group \
--db-parameter-group-family aurora-postgresql14 \
--description "description"
```

For Windows:

```
aws rds create-db-cluster-parameter-group ^
--endpoint-url endpoint-URL ^
--db-cluster-parameter-group-name parameter-group ^
--db-parameter-group-family aurora-postgresql14 ^
--description "description"
```

2. Modify your parameter group to turn on Babelfish.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
--endpoint-url endpoint-url \
--db-cluster-parameter-group-name parameter-group \
--parameters "ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
--endpoint-url endpoint-url ^
--db-cluster-parameter-group-name paramater-group ^
--parameters "ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot"
```

3. Identify your DB subnet group and the virtual private cloud (VPC) security group ID for your new DB cluster, and then call the `create-db-cluster` command.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
--db-cluster-identifier cluster-name \
--master-username postgres \
--master-user-password password \
--engine aurora-postgresql \
--engine-version 14.3 \
--vpc-security-group-ids security-group \
--db-subnet-group-name subnet-group-name \
--db-cluster-parameter-group-name parameter-group
```

For Windows:

```
aws rds create-db-cluster ^
--db-cluster-identifier cluster-name ^
--master-username postgres ^
--master-user-password password ^
--engine aurora-postgresql ^
--engine-version 14.3 ^
--vpc-security-group-ids security-group ^
--db-subnet-group-name subnet-group ^
--db-cluster-parameter-group-name parameter-group
```

4. Explicitly create the primary instance for your DB cluster. Use the name of the cluster that you created in step 3 for the --db-cluster-identifier argument when you call the [create-db-instance](#) command, as shown following.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier instance-name \
--db-instance-class db.r6g \
--db-subnet-group-name subnet-group \
--db-cluster-identifier cluster-name \
--engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier instance-name ^
--db-instance-class db.r6g ^
--db-subnet-group-name subnet-group ^
--db-cluster-identifier cluster-name ^
--engine aurora-postgresql
```

# Migrating a SQL Server database to Babelfish for Aurora PostgreSQL

You can use Babelfish for Aurora PostgreSQL to migrate an SQL Server database to an Amazon Aurora PostgreSQL DB cluster. Before migrating, review [Using Babelfish with a single database or multiple databases \(p. 1065\)](#).

## Topics

- [Overview of the migration process \(p. 1093\)](#)
- [Evaluating and handling differences between SQL Server and Babelfish \(p. 1094\)](#)
- [Import/export tools for migrating from SQL Server to Babelfish \(p. 1094\)](#)

## Overview of the migration process

The following summary overview lists the steps required to successfully migrate your SQL Server application and make it work with Babelfish. For information about the tools you can use for the export and import processes and for more detail, see [Import/export tools for migrating from SQL Server to Babelfish \(p. 1094\)](#).

1. Create a new Aurora PostgreSQL DB cluster with Babelfish turned on. To learn how, see [Creating a Babelfish for Aurora PostgreSQL DB cluster \(p. 1086\)](#).

To import the various SQL artifacts exported from your SQL Server database in the steps that follow, you connect to the Babelfish cluster using a native SQL Server tool such as `sqlcmd`. For more information, see [Using a SQL Server client to connect to your DB cluster \(p. 1100\)](#).

2. On the SQL Server database that you want to migrate, export the data definition language (DDL). The DDL is SQL code that describes database objects that contain user data (such as tables, indexes, and views) and user-written database code (such as stored procedures, user-defined functions, and triggers).

To do so, you can use a SQL Server client tool such as Microsoft SQL Server Management Studio (SMSS). Regardless of the tool, we recommend that you export your SQL Server DDL in two distinct phases:

- Generate the DDL for the table objects alone, without foreign keys, indexes, or other constraints.
- Generate the DDL for other objects, such as views and stored procedures.

For more information, see [Using SQL Server Management Studio \(SSMS\) to migrate to Babelfish \(p. 1095\)](#).

3. Export the data manipulation language (DML) for your SQL Server databases that you want to migrate. The DML is SQL code that inserts rows into the tables in your database.
4. Run an assessment tool to evaluate the scope of any changes that you might need to make so that Babelfish can effectively support the application running on SQL Server. For more information, see [Evaluating and handling differences between SQL Server and Babelfish \(p. 1094\)](#).
5. On your new Babelfish DB cluster, run the DDL to create only the schemas and tables with their primary key constraints.
6. To load the data, you can use the SSMS Import/Export Wizard or another tool. For more information, see [Import/export tools for migrating from SQL Server to Babelfish \(p. 1094\)](#). Make code adjustments as needed. This process might require multiple iterations.
7. Run the DML on your new Babelfish server to insert rows into the tables in your database.
8. Reconfigure your client application to connect to the Babelfish endpoint rather than your SQL Server database. For more information, see [Connecting to a Babelfish DB cluster \(p. 1097\)](#).

9. Modify your application as needed and retest. For more information, see [Differences between Babelfish for Aurora PostgreSQL and SQL Server \(p. 1108\)](#).

You still need to assess your client-side SQL queries. The schemas generated from your SQL Server instance convert only the server-side SQL code. We recommend that you take the following steps:

- Capture client-side queries by using the SQL Server Profiler with the TSQL\_Replay predefined template. This template captures T-SQL statement information that can then be replayed for iterative tuning and testing. You can start the profiler within SQL Server Management Studio, from the **Tools** menu. Choose **SQL Server Profiler** to open the profiler and choose the TSQL\_Replay template.

To use for your Babelfish migration, start a trace and then run your application using your functional tests. The profiler captures the T-SQL statements. When you finish testing, stop the trace. Save the result to an XML file with your client-side queries (File > Save as > Trace XML File for Replay).

For more information, see [SQL Server Profiler](#) in the Microsoft documentation. For more information about the TSQL\_Replay template, see [SQL Server Profiler Templates](#).

- For applications with complex client-side SQL queries, we recommend that you use Babelfish Compass to analyze these for Babelfish compatibility. If the analysis indicates that the client-side SQL statements contain unsupported SQL features, review the SQL aspects in the client application and modify as needed.

When you're satisfied with all testing, analysis, and any modifications need for your migrated application, you can start using your Babelfish database for production. To do so, stop the original database and redirect live client applications to use the Babelfish TDS port.

## Evaluating and handling differences between SQL Server and Babelfish

For best results, we recommend that you evaluate the generated DDL/DML and the client query code before actually migrating your SQL Server database application to Babelfish. Depending on the version of Babelfish and the specific features of SQL Server that your application implements, you might need to refactor your application or use alternatives for functionality that isn't yet fully supported in Babelfish.

To assess your SQL Server application code, you can use tools such as the following:

- Use Babelfish Compass on the generated DDL to determine to what extent the T-SQL code is supported by Babelfish. Identify T-SQL code that might need modifications before running on Babelfish. For more information about this tool, see [Babelfish Compass tool](#) on GitHub.
- Use the AWS Schema Conversion Tool to help with your migration. The AWS Schema Conversion Tool supports Babelfish as a virtual target, so you don't need to have a Babelfish DB cluster running to find out how well (or how poorly) your migration would work. To learn more, see [Using virtual targets](#) in the [AWS Schema Conversion Tool User Guide](#).

### Note

Babelfish Compass is an open-source tool. Report any issues with Babelfish Compass through GitHub rather than to AWS Support.

## Import/export tools for migrating from SQL Server to Babelfish

As of Babelfish 2.1.0 (Aurora PostgreSQL 14.3), you can choose one of the following tools to export your SQL code (DDL, DML) from SQL Server and then import into Babelfish.

- Use SQL Server Management Studio (SSMS) to export your DDL and DML from SQL Server. For more information, see [Using SQL Server Management Studio \(SSMS\) to migrate to Babelfish \(p. 1095\)](#).

- Use the SSMS Import/Export Wizard. This tool is available through the SSMS, but it's also available as a standalone tool. For more information, see [Welcome to SQL Server Import and Export Wizard](#) in the Microsoft documentation.
- Use the Microsoft bulk data copy program (bcp). Support for bcp in Babelfish 2.1.0 is experimental. Certain bcp options aren't supported, including `-E`, `-T`, and `-h`. This utility lets you copy data from a Microsoft SQL Server instance to a data file in the format you specify. For more information, see [bcp Utility](#) in the Microsoft documentation.

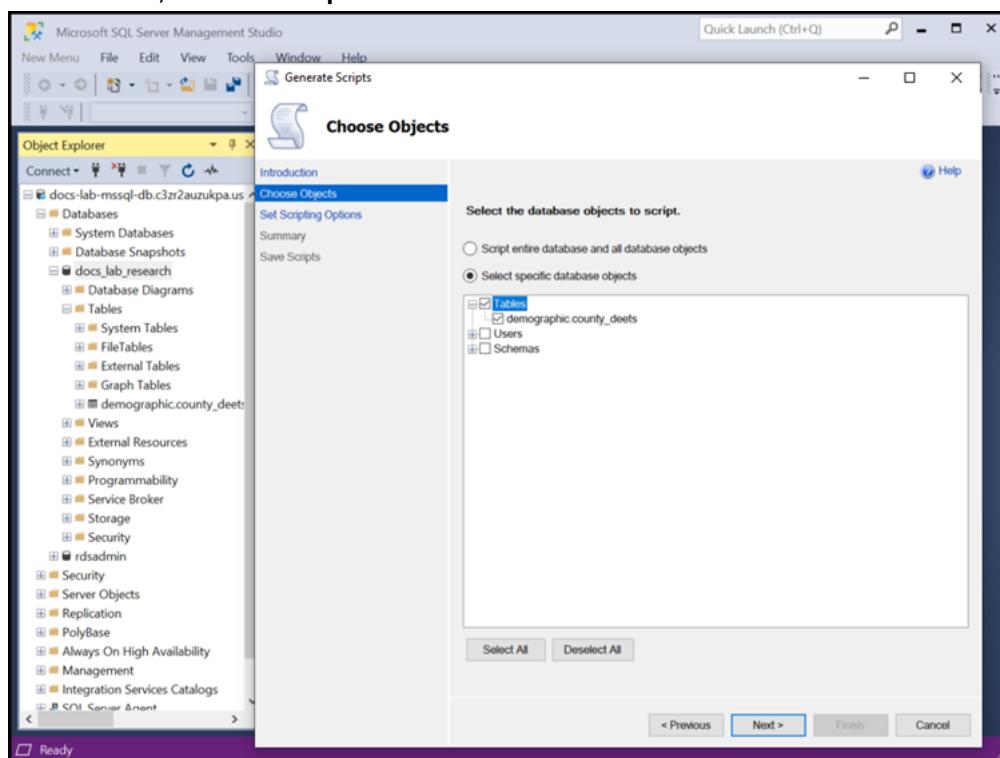

### **Important**

The converse approach isn't currently supported. In other words, you can't use SSMS or another tool to export T-SQL DDL from Babelfish-created objects based on the Babelfish catalogs. The DDL generated in this way isn't reliable for production use.

## Using SQL Server Management Studio (SSMS) to migrate to Babelfish

You can use SQL Server Management Studio (SSMS) to export DDL and DML from your SQL Server instance by following these steps.

1. Connect to your existing SQL Server instance.
2. Open the context menu (right-click) for a database name.
3. Choose **Tasks, Generate Scripts...** from the context menu.

4. On the **Choose Objects** pane, choose **Select specific database objects**. Choose **Tables**, select all tables. Choose **Next** to generate the one of two scripts to create the DDL to use on your Babelfish DB cluster.
5. On the **Set Scripting Options** page, choose **Advanced** to open the **Options** settings. Turn on triggers, logins, owners, and permissions. These are turned off by default in SSMS.
6. Save the script.
7. Repeat the process to generate scripts for the remaining DDL.

To export your DML, follow these steps:

1. Open the context (right-click) menu for a database name.
2. Choose **Tasks, Generate Scripts** from the context menu.
3. On the **Choose Objects** page, select the entire database or specific objects.
4. On the **Set Scripting Options** page, choose **Advanced** and for **Types of data to script**, choose **Data only**.
5. Save the script.

## Connecting to a Babelfish DB cluster

To connect to Babelfish, you connect to the endpoint of the Aurora PostgreSQL cluster running Babelfish. Your client can use one of the following client drivers compliant with TDS version 7.1 through 7.4:

- Open Database Connectivity (ODBC)
- OLE DB Driver/MSOLEDBSQL
- Java Database Connectivity (JDBC) version 8.2.2 (mssql-jdbc-8.2.2) and higher
- Microsoft SqlClient Data Provider for SQL Server
- .NET Data Provider for SQL Server
- SQL Server Native Client 11.0 (deprecated)
- OLE DB Provider/SQLOLEDB (deprecated)

With Babelfish, you run the following:

- SQL Server tools, applications, and syntax on the TDS port, by default port 1433.
- PostgreSQL tools, applications, and syntax on the PostgreSQL port, by default port 5432.

To learn more about connecting to Aurora PostgreSQL in general, see [Connecting to an Amazon Aurora PostgreSQL DB cluster \(p. 212\)](#).

### Topics

- [Finding the writer endpoint and port number \(p. 1097\)](#)
- [Creating C# or JDBC client connections to Babelfish \(p. 1099\)](#)
- [Using a SQL Server client to connect to your DB cluster \(p. 1100\)](#)
- [Using a PostgreSQL client to connect to your DB cluster \(p. 1103\)](#)

## Finding the writer endpoint and port number

To connect to your Babelfish DB cluster, you use the endpoint associated with the DB cluster's writer (primary) instance. The instance must have a status of **Available**. It can take up to 20 minutes for the instances to be available after creating the Babelfish for Aurora PostgreSQL DB cluster.

### To find your database endpoint

1. Open the console for Babelfish.
2. Choose **Databases** from the navigation pane.
3. Choose your Babelfish for Aurora PostgreSQL DB cluster from those listed to see its details.
4. On the **Connectivity & security** tab, note the available cluster **Endpoints** values. Use the cluster endpoint for the writer instance in your connection strings for any applications that perform database write or read operations.

The screenshot shows the AWS RDS console for the 'babelfish-workshop' database. In the 'Related' section, the cluster 'babelfish-workshop' is highlighted with a red circle. It contains two instances: 'babelfish-workshop-instance-1' (Writer instance) and 'babelfish-workshop-instance-2' (Reader instance). Both instances are listed as 'Available'. In the 'Endpoints' section, there are two entries: 'babelfish-workshop.cluster-ro...' (Reader instance) and 'babelfish-workshop.cluster-...' (Writer instance), both also circled in red.

DB identifier	Role	Engine	Region & AZ	Size	Status
babelfish-workshop	Regional cluster	Aurora PostgreSQL	us-east-1	2 instances	Available
babelfish-workshop-instance-1	Writer instance	Aurora PostgreSQL	us-east-1c	db.r6g.large	Available
babelfish-workshop-instance-2	Reader instance	Aurora PostgreSQL	us-east-1b	db.r6g.large	Available

Endpoint name	Status	Type	Port
babelfish-workshop.cluster-ro...	Available	Reader instance	5432, 1433 (Babelfish)
babelfish-workshop.cluster-...	Available	Writer instance	5432, 1433 (Babelfish)

For more information about Aurora DB cluster details, see [Creating an Amazon Aurora DB cluster \(p. 127\)](#).

## Creating C# or JDBC client connections to Babelfish

In the following you can find some examples of using C# and JDBC classes to connect to an Babelfish for Aurora PostgreSQL.

### Example : Using C# code to connect to a DB cluster

```
string dataSource = 'babelfishServer_11_24';

//Create connection
connectionString = @"Data Source=" + dataSource
    +";Initial Catalog=your-DB-name"
    +";User ID=user-id;Password=password";

SqlConnection cnn = new SqlConnection(connectionString);
cnn.Open();
```

### Example : Using generic JDBC API classes and interfaces to connect to a DB cluster

```
String dbServer =
    "database-babelfish.cluster-123abc456def.us-east-1-rds.amazonaws.com";
String connectionUrl = "jdbc:sqlserver://" + dbServer + ":1433;" +
    "databaseName=your-DB-name;user=user-id;password=password";

// Load the SQL Server JDBC driver and establish the connection.
System.out.print("Connecting Babelfish Server ... ");
Connection cnn = DriverManager.getConnection(connectionUrl);
```

### Example : Using SQL Server-specific JDBC classes and interfaces to connect to a DB cluster

```
// Create datasource.
SQLServerDataSource ds = new SQLServerDataSource();
ds.setUser("user-id");
ds.setPassword("password");
String babelfishServer =
    "database-babelfish.cluster-123abc456def.us-east-1-rds.amazonaws.com";

ds.setServerName(babelfishServer);
ds.setPortNumber(1433);
ds.setDatabaseName("your-DB-name");

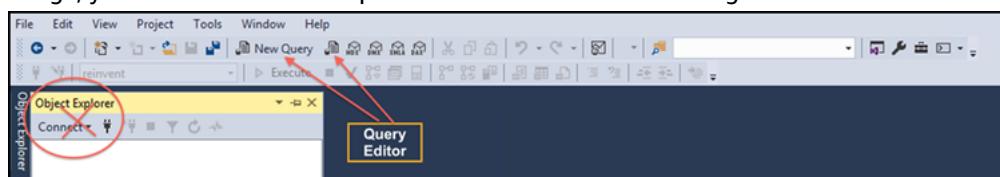

Connection con = ds.getConnection();
```

## Using a SQL Server client to connect to your DB cluster

You can use a SQL Server client to connect with Babelfish on the TDS port. As of Babelfish 2.1.0 and higher releases, you can use the SSMS Object Explorer or the SSMS Query Editor to connect to your Babelfish cluster.

### Limitations

- Using `PARSE` to check SQL syntax doesn't work as it should. Rather than checking the syntax without running the query, the `PARSE` command runs the query but doesn't display any results. Using the SSMS `<Ctrl><F5>` key combination to check syntax has the same anomalous behavior, that is, Babelfish unexpectedly runs the query without providing any output.
- Babelfish doesn't support MARS (Multiple Active Result Sets). Be sure that any client applications that you use to connect to Babelfish aren't set to use MARS.
- For Babelfish 1.3.0 and older versions, only the Query Editor is supported for SSMS. To use SSMS with Babelfish, be sure to open the Query Editor connection dialog in SSMS, and not the Object Explorer. If the Object Explorer dialog does open, cancel the dialog and re-open the Query Editor. In the following image, you can find the menu options to choose when connecting to Babelfish 1.3.0 or older versions.

For more information about interoperability and behavioral differences between SQL Server and Babelfish, see [Differences between Babelfish for Aurora PostgreSQL and SQL Server \(p. 1108\)](#).

## Using sqlcmd to connect to the DB cluster

You can connect to and interact with an Aurora PostgreSQL DB cluster that supports Babelfish by using the SQL Server `sqlcmd` command line client. Use the following command to connect.

```
sqlcmd -S endpoint, port -U login-id -P password -d your-DB-name
```

The options are as follows:

- `-S` is the endpoint and (optional) TDS port of the DB cluster.
- `-U` is the login name of the user.
- `-P` is the password associated with the user.
- `-d` is the name of your Babelfish database.

After connecting, you can use many of the same commands that you use with SQL Server. For some examples, see [Getting information from the Babelfish system catalog \(p. 1106\)](#).

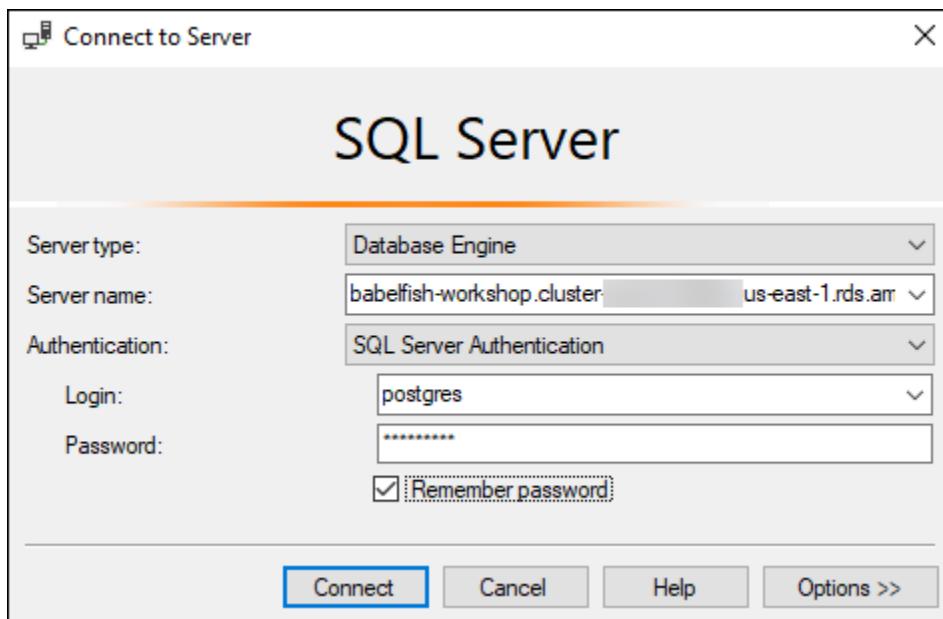

## Using SSMS to connect to the DB cluster

You can connect to an Aurora PostgreSQL DB cluster running Babelfish by using Microsoft SQL Server Management Studio (SSMS). SSMS includes a variety of tools, including the SQL Server Import and Export Wizard discussed in [Migrating a SQL Server database to Babelfish for Aurora PostgreSQL \(p. 1093\)](#). For more information about SSMS, see [Download SQL Server Management Studio \(SSMS\)](#) in the Microsoft documentation.

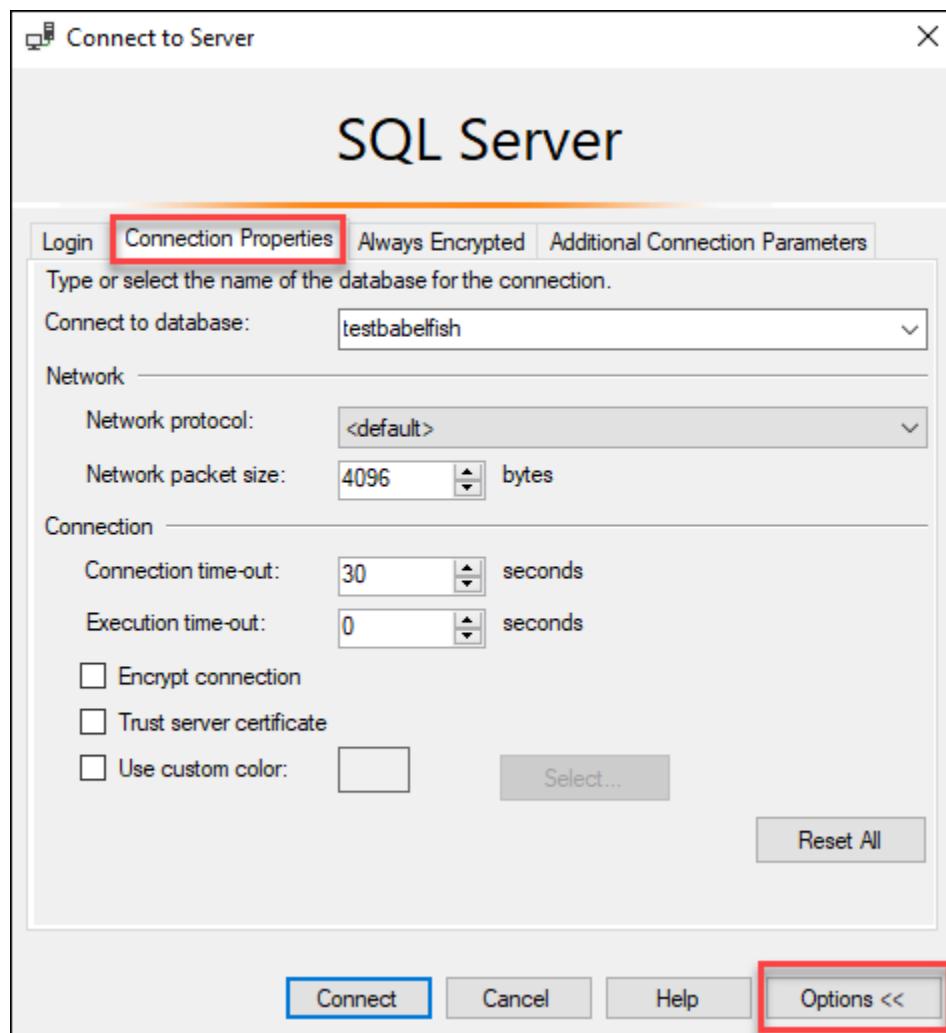

### To connect to your Babelfish database with SSMS

1. Start SSMS.
2. Open the **Connect to Server** dialog box. To continue with the connection, do one of the following:
  - Choose **New Query**.
  - If the Query Editor is open, choose **Query, Connection, Connect**.
3. Provide the following information for your database:
  - a. For **Server type**, choose **Database Engine**.
  - b. For **Server name**, enter the DNS name. For example, your server name should look similar to the following.

*cluster-name.cluster-555555555555.aws-region.rds.amazonaws.com,1433*
  - c. For **Authentication**, choose **SQL Server Authentication**.
  - d. For **Login**, enter the user name that you chose when you created your database.
  - e. For **Password**, enter the password that you chose when you created your database.

4. (Optional) Choose **Options**, and then choose the **Connection Properties** tab.

5. (Optional) For **Connect to database**, specify the name of the migrated SQL Server database to connect to, and choose **Connect**.

If a message appears indicating that SSMS can't apply connection strings, choose **OK**.

If you are having trouble connecting to Babelfish, see [Connection failure \(p. 1123\)](#).

For more information about SQL Server connection issues, see [Troubleshooting connections to your SQL Server DB instance](#) in the *Amazon RDS User Guide*.

## Using a PostgreSQL client to connect to your DB cluster

You can use a PostgreSQL client to connect to Babelfish on the PostgreSQL port.

### Using psql to connect to the DB cluster

You can query an Aurora PostgreSQL DB cluster that supports Babelfish with the `psql` command line client. When connecting, use the PostgreSQL port (by default, port 5432). Typically, you don't need to specify the port number unless you changed it from the default. Use the following command to connect to Babelfish from the `psql` client:

```
psql -h bfish-db.cluster-123456789012.aws-region.rds.amazonaws.com
      -p 5432 -U postgres -d babelfish_db -p
```

The parameters are as follows:

- `-h` – The host name of the DB cluster (cluster endpoint) that you want to access.
- `-p` – The PostgreSQL port number used to connect to your DB instance.
- `-d` – `babelfish_db`
- `-U` – The database user account that you want to access. (The example shows the default master username.)
- `-p` – The password of the database user.

When you run a SQL command on the `psql` client, you end the command with a semicolon. For example, the following SQL command queries the [pg\\_tables system view](#) to return information about each table in the database.

```
SELECT * FROM pg_tables;
```

The `psql` client also has a set of built-in metacommands. A *metacommand* is a shortcut that adjusts formatting or provides a shortcut that returns meta-data in an easy-to-use format. For example, the following metacommand returns similar information to the previous SQL command:

```
\d
```

Metacommands don't need to be terminated with a semicolon (;).

To exit the `psql` client, enter `\q`.

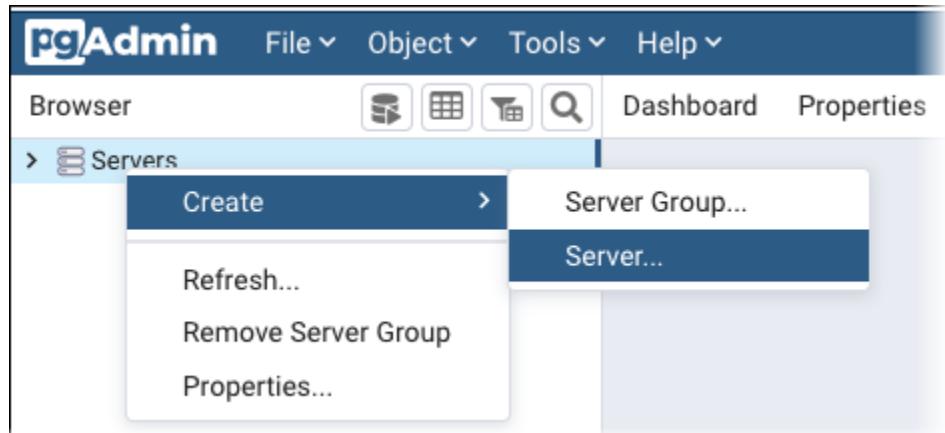

For more information about using the `psql` client to query an Aurora PostgreSQL cluster, see the [PostgreSQL documentation](#).

### Using pgAdmin to connect to the DB cluster

You can use the pgAdmin client to access your data in native PostgreSQL dialect.

#### To connect to the cluster with the pgAdmin client

1. Download and install the pgAdmin client from the [pgAdmin website](#).
2. Open the client and authenticate with pgAdmin.
3. Open the context (right-click) menu for **Servers**, and then choose **Create, Server**.

4. Enter information in the **Create - Server** dialog box.

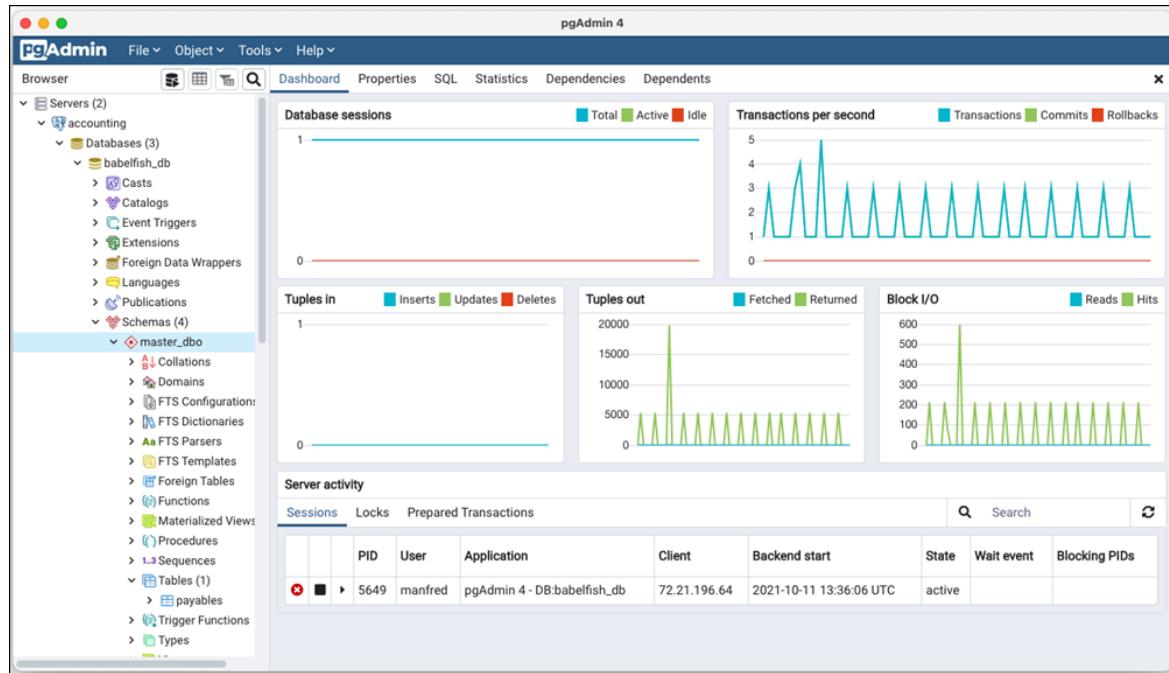

On the **Connection** tab, add the Aurora PostgreSQL cluster address for **Host** and the PostgreSQL port number (by default, 5432) for **Port**. Provide authentication details, and choose **Save**.

The screenshot shows the "Create - Server" dialog box with the "Connection" tab selected. The form fields are as follows:

Setting	Value
Host name/address	babelfish_db.cluster- .us-east-1.rds.ama
Port	5432
Maintenance database	babelfish_db
Username	postgres
Kerberos authentication?	(Toggle switch off)
Password	.....
Save password?	(Toggle switch off)
Role	(Empty field)
Service	(Empty field)

At the bottom of the dialog are buttons for "Close", "Reset", and "Save".

After connecting, you can use pgAdmin functionality to monitor and manage your Aurora PostgreSQL cluster on the PostgreSQL port.

To learn more, see the [pgAdmin web page](#).

## Working with Babelfish

Following, you can find usage information for Babelfish, including some of the differences between working with Babelfish and SQL Server, and between Babelfish and PostgreSQL databases.

### Topics

- [Getting information from the Babelfish system catalog \(p. 1106\)](#)
- [Differences between Babelfish for Aurora PostgreSQL and SQL Server \(p. 1108\)](#)
- [Using Babelfish features with limited implementation \(p. 1113\)](#)
- [Using explain plan to improve Babelfish query performance \(p. 1114\)](#)
- [Using Aurora PostgreSQL extensions with Babelfish \(p. 1117\)](#)

## Getting information from the Babelfish system catalog

You can obtain information about the database objects that are stored in your Babelfish cluster by querying many of the same system views as used in SQL Server. Each new release of Babelfish adds support for more system views. For a list of available views currently available, see the [SQL Server system catalog views table](#).

These system views provide information from the system catalog (`sys.schemas`). In the case of Babelfish, these views contain both SQL Server and PostgreSQL system schemas. To query Babelfish for system catalog information, you can use the TDS port or the PostgreSQL port, as shown in the following examples.

- **Query the T-SQL port using `sqlcmd` or another SQL Server client.**

```
1> SELECT * FROM sys.schemas
2> GO
```

This query returns SQL Server and Aurora PostgreSQL system schemas, as shown in the following.

```
name
-----
demographic_dbo
public
sys
master_dbo
tempdb_dbo
...
```

- **Query the PostgreSQL port using `psql` or `pgAdmin`.** This example uses the `psql` list schemas metacommand (`\dn`):

```
babelfish_db=> \dn
```

The query returns the same result set as that returned by `sqlcmd` on the T-SQL port.

```
List of schemas
Name
-----
demographic_dbo
public
sys
```

```
master_dbo
tempdb_dbo
...
```

## SQL Server system catalogs available in Babelfish

In the following table you can find the SQL Server views currently implemented in Babelfish. For more information about the system catalogs in SQL Server, see [System Catalog Views \(Transact-SQL\)](#) in Microsoft documentation.

<b>View name</b>	<b>Description or Babelfish limitation (if any)</b>
<code>sys.all_columns</code>	All columns in all tables and views
<code>sys.all_objects</code>	All objects in all schemas
<code>sys.all_sql_modules</code>	The union of <code>sys.sql_modules</code> and <code>sys.system_sql_modules</code>
<code>sys.all_views</code>	All views in all schemas
<code>sys.columns</code>	All columns in user-defined tables and views
<code>sys.configurations</code>	Babelfish support limited to a single read-only configuration.
<code>sys.data_spaces</code>	Contains a row for each data space. This can be a filegroup, partition scheme, or FILESTREAM data filegroup.
<code>sys.database_files</code>	A per-database view that contains one row for each file of a database as stored in the database itself.
<code>sys.database_mirroring</code>	For information, see <a href="#">sys.database_mirroring</a> in Microsoft Transact-SQL documentation.
<code>sys.database_principals</code>	For information, see <a href="#">sys.database_principals</a> in Microsoft Transact-SQL documentation.
<code>sys.database_role_members</code>	For information, see <a href="#">sys.database_role_members</a> in Microsoft Transact-SQL documentation.
<code>sys.databases</code>	All databases in all schemas
<code>sys.dm_exec_connections</code>	For information, see <a href="#">sys.dm_exec_connections</a> in Microsoft Transact-SQL documentation.
<code>sys.dm_exec_sessions</code>	For information, see <a href="#">sys.dm_exec_sessions</a> in Microsoft Transact-SQL documentation.
<code>sys.dm_hadr_database_replica_states</code>	For information, see <a href="#">sys.dm_hadr_database_replica_states</a> in Microsoft Transact-SQL documentation.
<code>sys.dm_os_host_info</code>	For information, see <a href="#">sys.dm_os_host_info</a> in Microsoft Transact-SQL documentation.

<b>View name</b>	<b>Description or Babelfish limitation (if any)</b>
<code>sys.endpoints</code>	For information, see <a href="#">sys.endpoints</a> in Microsoft Transact-SQL documentation.
<code>sys.indexes</code>	For information, see <a href="#">sys.indexes</a> in Microsoft Transact-SQL documentation.
<code>sys.languages</code>	For information, see <a href="#">sys.languages</a> in Microsoft Transact-SQL documentation.
<code>sys.schemas</code>	All schemas
<code>sys.server_principals</code>	All logins and roles
<code>sys.sql_modules</code>	For information, see <a href="#">sys.sql_modules</a> in Microsoft Transact-SQL documentation.
<code>sys.sysconfigures</code>	Babelfish support limited to a single read-only configuration.
<code>sys.syscurconfigs</code>	Babelfish support limited to a single read-only configuration.
<code>sys.sysprocesses</code>	For information, see <a href="#">sys.sysprocesses</a> in Microsoft Transact-SQL documentation.
<code>sys.system_sql_modules</code>	For information, see <a href="#">sys.system_sql_modules</a> in Microsoft Transact-SQL documentation.
<code>sys.table_types</code>	For information, see <a href="#">sys.table_types</a> in Microsoft Transact-SQL documentation.
<code>sys.tables</code>	All tables in a schema
<code>sys.xml_schema_collections</code>	For information, see <a href="#">sys.xml_schema_collections</a> in Microsoft Transact-SQL documentation.

PostgreSQL implements system catalogs that are similar to the SQL Server object catalog views. For a complete list of system catalogs, see [System Catalogs](#) in the PostgreSQL documentation.

## Differences between Babelfish for Aurora PostgreSQL and SQL Server

Babelfish is an evolving Aurora PostgreSQL feature, with new functionality added in each release since the initial offering in Aurora PostgreSQL 13.4. It's designed to provide T-SQL semantics on top of PostgreSQL through the T-SQL dialect using the TDS port. Each new version of Babelfish adds features and functions that better align with T-SQL functionality and behavior, as shown in the [Supported functionality in Babelfish by version \(p. 1137\)](#) table. For best results when working with Babelfish, we recommend that you understand the differences that currently exist between the T-SQL supported by SQL Server and Babelfish for the latest version. To learn more, see [T-SQL differences in Babelfish \(p. 1109\)](#).

In addition to the differences between T-SQL supported by Babelfish and SQL Server, you might also need to consider interoperability issues between Babelfish and PostgreSQL in the context of the Aurora PostgreSQL DB cluster. As mentioned previously, Babelfish supports T-SQL semantics on top of PostgreSQL through the T-SQL dialect using the TDS port. At the same time, the Babelfish database can also be accessed through the standard PostgreSQL port with PostgreSQL SQL statements. If

you're considering using both PostgreSQL and Babelfish functionality in a production deployment, you need to be aware of the potential interoperability issues between schema names, identifiers, permissions, transactional semantics, multiple result sets, default collations, and so on. In simple terms, when PostgreSQL statements or PostgreSQL access occur in the context of Babelfish, interference between PostgreSQL and Babelfish can occur and can potentially affect syntax, semantics, and compatibility when new versions of Babelfish are released. For complete information and guidance about all the considerations, see the [Guidance on Babelfish Interoperability](#) in the Babelfish for PostgreSQL documentation.

**Note**

Before using both PostgreSQL native functionality and Babelfish functionality in the same application context, we strongly recommend that you consider the issues discussed in the [Guidance on Babelfish Interoperability](#) in the Babelfish for PostgreSQL documentation. These interoperability issues (Aurora PostgreSQL and Babelfish) are relevant only if you plan to use the PostgreSQL database instance in the same application context as Babelfish.

## T-SQL differences in Babelfish

Following, you can find a table of T-SQL functionality as supported in the current release of Babelfish with some notes about differences in the behavior from that of SQL Server.

For more information about support in various versions, see [Supported functionality in Babelfish by version \(p. 1137\)](#). For information about features that currently aren't supported, see [Unsupported functionality in Babelfish \(p. 1128\)](#).

Babelfish is available with Aurora PostgreSQL-Compatible Edition. For more information about Babelfish releases, see the [Release Notes for Aurora PostgreSQL](#).

Functionality or syntax	Description of behavior or difference
\ (line continuation character)	The line continuation character (a backslash prior to a newline) for character and hexadecimal strings isn't currently supported. For character strings, the backslash-newline is interpreted as characters in the string. For hexadecimal strings, backslash-newline results in a syntax error.
@@version	The format of the value returned by @@version is slightly different from the value returned by SQL Server. Your code might not work correctly if it depends on the formatting of @@version.
Aggregate functions	Aggregate functions are partially supported (AVG, COUNT, COUNT_BIG, GROUPING, MAX, MIN, STRING_AGG, and SUM are supported). For a list of unsupported aggregate functions, see <a href="#">Functions that aren't supported (p. 1132)</a> .
ALTER TABLE	Supports adding or dropping a single column or constraint only.
BACKUP statement	Aurora PostgreSQL snapshots of a database are dissimilar to backup files created in SQL Server. Also, the granularity of when a backup and restore occurs might be different between SQL Server and Aurora PostgreSQL.
Blank column names with no column alias	The <code>sqlcmd</code> and <code>psql</code> utilities handle columns with blank names differently: <ul style="list-style-type: none"> <li>SQL Server <code>sqlcmd</code> returns a blank column name.</li> <li>PostgreSQL <code>psql</code> returns a generated column name.</li> </ul>
CHECKSUM function	Babelfish and SQL Server use different hashing algorithms for the CHECKSUM function. As a result, the hash values generated by

Functionality or syntax	Description of behavior or difference
	CHECKSUM function in Babelfish might be different from those generated by CHECKSUM function in SQL Server.
Column default	When creating a column default, the constraint name is ignored. To drop a column default, use the following syntax: ALTER TABLE...ALTER COLUMN..DROP DEFAULT...
Constraints	PostgreSQL doesn't support turning on and turning off individual constraints. The statement is ignored and a warning is raised.
Constraints created with DESC (descending) columns	Constraints are created with ASC (ascending) columns.
Constraints with IGNORE_DUP_KEY	Constraints are created without this property.
CREATE, ALTER, DROP SERVER ROLE	<p>ALTER SERVER ROLE is supported only for sysadmin. All other syntax is unsupported.</p> <p>The T-SQL user in Babelfish has an experience that is similar to SQL Server for the concepts of a login (server principal), a database, and a database user (database principal).</p> <p>Only the dbo user is available in Babelfish user databases. To operate as the dbo user, a login must be a member of the server-level sysadmin role (ALTER SERVER ROLE sysadmin ADD MEMBER <a href="#">login</a>). Logins without sysadmin role can currently access only master and tempdb as the guest user.</p> <p>Currently, because Babelfish supports only the dbo user in user databases, all application users must use a login that is a sysadmin member. You can't create a user with lesser privileges, such as read-only on certain tables.</p>
CREATE, ALTER LOGIN clauses are supported with limited syntax	The CREATE LOGIN... PASSWORD clause, ...DEFAULT_DATABASE clause, and ...DEFAULT_LANGUAGE clause are supported. The ALTER LOGIN... PASSWORD clause is supported, but ALTER LOGIN... OLD_PASSWORD clause isn't supported. Only a login that is a sysadmin member can modify a password.
CREATE DATABASE case-sensitive collation	Case-sensitive collations aren't supported with the CREATE DATABASE statement.
CREATE DATABASE keywords and clauses	Options except COLLATE and CONTAINMENT=NONE aren't supported. The COLLATE clause is accepted and is always set to the value of <code>babelfishpg_tsql.server_collation_name</code> .
CREATE SCHEMA... supporting clauses	You can use the CREATE SCHEMA command to create an empty schema. Use additional commands to create schema objects.
CREATE, ALTER LOGIN clauses are supported with limited syntax	The CREATE LOGIN... PASSWORD clause, ...DEFAULT_DATABASE clause, and ...DEFAULT_LANGUAGE clause are supported. The ALTER LOGIN... PASSWORD clause is supported, but ALTER LOGIN... OLD_PASSWORD clause isn't supported. Only a login that is a sysadmin member can modify a password.
LOGIN objects	All options for LOGIN objects are supported except for PASSWORD, DEFAULT_DATABASE, ENABLE, DISABLE.

Functionality or syntax	Description of behavior or difference
Procedure or function parameter limit	Babelfish supports a maximum of 100 parameters for a procedure or function.
RESTORE statement	Aurora PostgreSQL snapshots of a database are dissimilar to backup files created in SQL Server. Also, the granularity of when the backup and restore occurs might be different between SQL Server and Aurora PostgreSQL.
ROLLBACK: table variables don't support transactional rollback	Processing might be interrupted if a rollback occurs in a session with table variables.
ROWGUIDCOL	This clause is currently ignored. Queries referencing \$GUIDCOL cause a syntax error.
SEQUENCE object support	SEQUENCE objects are supported for the data types tinyint, smallint, int, bigint, numeric, and decimal.  Aurora PostgreSQL supports precision to 19 places for data types numeric and decimal in a SEQUENCE.
Server-level roles	The sysadmin server-level role is supported. Other server-level roles (other than sysadmin) aren't supported.
Database-level roles other than db_owner	The db_owner database-level roles is supported. Other database-level roles (other than db_owner) aren't supported.
SQL keyword SPARSE	The keyword SPARSE is accepted and ignored.
SQL keyword clause ON <i>filegroup</i>	This clause is currently ignored.
SQL keywords CLUSTERED and NONCLUSTERED for indexes and constraints	Babelfish accepts and ignores the CLUSTERED and NONCLUSTERED keywords.
sysdatabases.cmptlevel	sysdatabases.cmptlevel are always NULL.
tempdb isn't reinitialized at restart	Permanent objects (like tables and procedures) created in tempdb aren't removed when the database is restarted.
TEXTIMAGE_ON <i>filegroup</i>	Babelfish ignores the TEXTIMAGE_ON <i>filegroup</i> clause.
Time precision	Babelfish supports 6-digit precision for fractional seconds. No adverse effects are anticipated with this behavior.
Transaction isolation levels	READUNCOMMITTED is treated the same as READCOMMITTED. REPEATABLEREAD, and SERIALIZABLE aren't supported.
Virtual computed columns (non-persistent)	Virtual computed columns are created as persistent.
WITHOUT SCHEMABINDING clause	This clause isn't supported in functions, procedures, triggers, or views. The object is created, but as if WITH SCHEMABINDING was specified.

## Using Babelfish features with limited implementation

Each new version of Babelfish adds support for features that better align with T-SQL functionality and behavior. Still, there are some unsupported features and differences in the current implementation. In the following, you can find information about functional differences between Babelfish and T-SQL, with some workarounds or usage notes.

As of version 1.2.0 of Babelfish, the following features currently have limited implementations:

- **SQL Server catalogs (system views)** – The catalogs `sys.sysconfigures`, `sys.syscurconfigs`, and `sys.configurations` support a single read-only configuration only. The `sp_configure` isn't currently supported. For more information about the other SQL Server views implemented by Babelfish, see [Getting information from the Babelfish system catalog \(p. 1106\)](#).
- **GRANT permissions** – `GRANT...TO PUBLIC` is supported, but `GRANT..TO PUBLIC WITH GRANT OPTION` is not currently supported.
- **SQL Server ownership chain and permission mechanism limitation** – In Babelfish, the SQL Server ownership chain works for views but not for stored procedures. This means that procedures must be granted explicit access to other objects owned by the same owner as the calling procedures. In SQL Server, granting the caller `EXECUTE` permissions on the procedure is sufficient to call other objects owned by same owner. In Babelfish, caller must also be granted permissions on the objects accessed by the procedure.
- **Resolution of unqualified (without schema name) object references** – When a SQL object (procedure, view, function or trigger) references an object without qualifying it with a schema name, SQL Server resolves the object's schema name by using the schema name of the SQL object in which the reference occurs. Currently, Babelfish resolves this differently, by using the default schema of the database user executing the procedure.
- **Default schema changes, sessions, and connections** – If users change their default schema with `ALTER USER...WITH DEFAULT SCHEMA`, the change takes effect immediately in that session. However, for other currently connected sessions belonging to the same user, the timing differs, as follows:
  - For SQL Server: – The change takes effect across all other connections for this user immediately.
  - For Babelfish: – The change takes effect for this user for new connections only.
- **ROWVERSION and TIMESTAMP datatypes implementation and escape hatch setting**
  - The `ROWVERSION` and `TIMESTAMP` datatypes are now supported in Babelfish. To use `ROWVERSION` or `TIMESTAMP` in Babelfish, you must change the setting for the escape hatch `babelfishpg_tsql.escape_hatch_rowversion` from its default (`strict`) to `ignore`. The Babelfish implementation of the `ROWVERSION` and `TIMESTAMP` datatypes is mostly semantically identical to SQL Server, with the following exceptions:
    - The built-in `@@DBTS` function behaves similarly to SQL Server, but with small differences. Rather than returning the last-used value for `SELECT @@DBTS`, Babelfish generates a new timestamp, due to the underlying PostgreSQL database engine and its multi-version concurrency control (MVCC) implementation.
    - In SQL Server, every inserted or updated row gets a unique `ROWVERSION/TIMESTAMP` value. In Babelfish, every inserted row updated by the same statement is assigned the same `ROWVERSION/TIMESTAMP` value.

For example, when an `UPDATE` statement or `INSERT-SELECT` statement affects multiple rows, in SQL Server, the affected rows all have different values in their `ROWVERSION/TIMESTAMP` column. In Babelfish (PostgreSQL), the rows have the same value.

- In SQL Server, when you create a new table with `SELECT-INTO`, you can cast an explicit value (such as `NULL`) to a to-be-created `ROWVERSION/TIMESTAMP` column. When you do the same thing in Babelfish, an actual `ROWVERSION/TIMESTAMP` value is assigned to each row in the new table for you, by Babelfish.

These minor differences in ROWVERSION/TIMESTAMP datatypes shouldn't have an adverse impact on applications running on Babelfish.

**Schema creation, ownership, and permissions** – Permissions to create objects in a schema that was created by the database owner (using `CREATE SCHEMA...AUTHORIZATION DBO`) differ for SQL Server and Babelfish non-DBO users, as shown in the following table:

Database user (non-DBO) can do the following:	SQL Server	Babelfish
Create objects in the schema without additional grants by the DBO?	No	Yes
Reference objects created in the schema by DBO without additional grants?	Yes	No

## Using explain plan to improve Babelfish query performance

Starting with version 2.1.0, Babelfish includes two functions that transparently use the PostgreSQL optimizer to generate estimated and actual query plans for T-SQL queries on the TDS port. These functions are similar to using `SET STATISTICS PROFILE` or `SET SHOWPLAN_ALL` with SQL Server databases to identify and improve slow running queries.

**Note**

Getting query plans from functions, control flows, and cursors isn't currently supported.

In the table you can find a comparison of query plan explain functions across SQL Server, Babelfish, and PostgreSQL.

SQL Server	Babelfish	PostgreSQL
<code>SHOWPLAN_ALL</code>	<code>BABELFISH_SHOWPLAN_ALL</code>	<code>EXPLAIN</code>
<code>STATISTICS PROFILE</code>	<code>BABELFISH_STATISTICS PROFILE</code>	<code>EXPLAIN ANALYZE</code>
Uses the SQL Server optimizer	Uses the PostgreSQL optimizer	Uses the PostgreSQL optimizer
SQL Server input and output format	SQL Server input and PostgreSQL output format	PostgreSQL input and output format
Set for the session	Set for the session	Apply to a specific statement
Supports the following:	Supports the following:	Supports the following:
<ul style="list-style-type: none"> <li>• <code>SELECT</code></li> <li>• <code>INSERT</code></li> <li>• <code>UPDATE</code></li> <li>• <code>DELETE</code></li> <li>• <code>CURSOR</code></li> <li>• <code>CREATE</code></li> <li>• <code>EXECUTE</code></li> <li>• <code>EXEC</code> and functions, including control flow (<code>CASE</code>, <code>WHILE-BREAK-CONTINUE</code>, <code>WAITFOR</code>, <code>BEGIN-END</code>, <code>IF-ELSE</code>, and so on)</li> </ul>	<ul style="list-style-type: none"> <li>• <code>SELECT</code></li> <li>• <code>INSERT</code></li> <li>• <code>UPDATE</code></li> <li>• <code>DELETE</code></li> <li>• <code>CREATE</code></li> <li>• <code>EXECUTE</code></li> <li>• <code>EXEC</code></li> </ul>	<ul style="list-style-type: none"> <li>• <code>SELECT</code></li> <li>• <code>INSERT</code></li> <li>• <code>UPDATE</code></li> <li>• <code>DELETE</code></li> <li>• <code>CURSOR</code></li> <li>• <code>CREATE</code></li> <li>• <code>EXECUTE</code></li> </ul>

Use the Babelfish functions as follows:

- SET BABELFISH\_SHOWPLAN\_ALL [ON|OFF] – Set to ON to generate an estimated query execution plan. This function implements the behavior of the PostgreSQL EXPLAIN command. Use this command to obtain the explain plan for given query.
- SET BABELFISH\_STATISTICS PROFILE [ON|OFF] – Set to ON for actual query execution plans. This function implements the behavior of PostgreSQL's EXPLAIN ANALYZE command.

For more information about PostgreSQL EXPLAIN and EXPLAIN ANALYZE see [EXPLAIN](#) in the PostgreSQL documentation.

For example, the following command sequence turns on query planning and then returns an estimated query execution plan for the SELECT statement without running the query. This example uses the SQL Server sample northwind database using the sqlcmd command-line tool to query the TDS port:

```
1> SET BABELFISH_SHOWPLAN_ALL ON
2> GO
1> SELECT t.territoryid, e.employeeid FROM
2> dbo.employeeteritories e, dbo.territories t
3> WHERE e.territoryid=e.territoryid ORDER BY t.territoryid;
4> GO

QUERY PLAN
-----
Query Text: SELECT t.territoryid, e.employeeid FROM
dbo.employeeteritories e, dbo.territories t
WHERE e.territoryid=e.territoryid ORDER BY t.territoryid
Sort (cost=6231.74..6399.22 rows=66992 width=10)
Sort Key: t.territoryid NULLS FIRST
-> Nested Loop (cost=0.00..861.76 rows=66992 width=10)
    -> Seq Scan on employeeteritories e (cost=0.00..22.70 rows=1264 width=4)
        Filter: ((territoryid)::"varchar" IS NOT NULL)
    -> Materialize (cost=0.00..1.79 rows=53 width=6)
        -> Seq Scan on territories t (cost=0.00..1.53 rows=53 width=6)
```

When you finish reviewing and adjusting your query, you turn off the function as shown following:

```
1> SET BABELFISH_SHOWPLAN_ALL OFF
```

With BABELFISH\_STATISTICS PROFILE set to ON, each executed query returns its regular result set followed by an additional result set that shows actual query execution plans. Babelfish generates the query plan that provides the fastest result set when it invokes the SELECT statement.

```
1> SET BABELFISH_STATISTICS PROFILE ON
1>
2> GO
1> SELECT e.employeeid, t.territoryid FROM
2> dbo.employeeteritories e, dbo.territories t
3> WHERE t.territoryid=e.territoryid ORDER BY t.territoryid;
4> GO
```

The result set and the query plan are returned (this example shows only the query plan).

**QUERY PLAN**

```
-----
Query Text: SELECT e.employeedid, t.territoryid FROM
dbo.employeeterritories e, dbo.territories t
WHERE t.territoryid=e.territoryid ORDER BY t.territoryid
Sort  (cost=42.44..43.28 rows=337 width=10)
      Sort Key: t.territoryid NULLS FIRST

->  Hash Join  (cost=2.19..28.29 rows=337 width=10)
    Hash Cond: ((e.territoryid)::"varchar" = (t.territoryid)::"varchar")
        ->  Seq Scan on employeeterritories e  (cost=0.00..22.70 rows=1270 width=36)
        ->  Hash  (cost=1.53..1.53 rows=53 width=6)
            ->  Seq Scan on territories t  (cost=0.00..1.53 rows=53 width=6)
```

To learn more about how to analyze your queries and the results returned by the PostgreSQL optimizer, see [explain.depesz.com](https://explain.depesz.com). For more information about PostgreSQL EXPLAIN and EXPLAIN ANALYZE, see [EXPLAIN](#) in the PostgreSQL documentation.

## Parameters that control Babelfish explain options

You can use the parameters shown in the following table to control the type of information that's displayed by your query plan.

Parameter	Description
<code>babelfishpg_tsql.explain_buffers</code>	A boolean that turns on (and off) buffer usage information for the optimizer. (Default: off) (Allowable: off, on)
<code>babelfishpg_tsql.explain_costs</code>	A boolean that turns on (and off) estimated startup and total cost information for the optimizer. (Default: on) (Allowable: off, on)
<code>babelfishpg_tsql.explain_format</code>	Specifies the output format for the EXPLAIN plan. (Default: text) (Allowable: text, xml, json, yaml)
<code>babelfishpg_tsql.explain_settings</code>	A boolean that turns on (or off) the inclusion of information about configuration parameters in the EXPLAIN plan output. (Default: off) (Allowable: off, on)
<code>babelfishpg_tsql.explain_summary</code>	A boolean that turns on (or off) summary information such as total time after the query plan. (Default: off) (Allowable: off, on)
<code>babelfishpg_tsql.explain_timing</code>	A boolean that turns on (or off) actual startup time and time spent in each node in the output. (Default: off) (Allowable: off, on)
<code>babelfishpg_tsql.explain_verbose</code>	A boolean that turns on (or off) the most detailed version of an explain plan. (Default: off) (Allowable: off, on)
<code>babelfishpg_tsql.explain_wal</code>	A boolean that turns on (or off) generation of WAL record information as part of an explain plan. (Default: off) (Allowable: off, on)

You can check the values of any Babelfish-related parameters on your system by using either PostgreSQL client or SQL Server client. You can get your current parameter values as follows:

```
1> :setvar SQLCMDMAXVARTYPEWIDTH 35
2> :setvar SQLCMDMAXFIXEDTYPEWIDTH 10
3> SELECT name,
4> setting,
5> short_desc,
6> pending_restart
7> FROM pg_settings
8> WHERE name LIKE '%babelfishpg_tsql.explain%';
9> GO
```

In the following output, you can see that all settings on this particular Babelfish DB cluster are at their default values. Not all output is shown in this example.

name	setting	short_desc
babelfishpg_tsql.explain_buffers	off	Include information on buffer usage
babelfishpg_tsql.explain_costs	on	Include information on estimated st
babelfishpg_tsql.explain_format	text	Specify the output format, which ca
babelfishpg_tsql.explain_settings	off	Include information on configuratio
babelfishpg_tsql.explain_summary	off	Include summary information (e.g.,
babelfishpg_tsql.explain_timing	off	Include actual startup time and tim
babelfishpg_tsql.explain_verbose	off	Display additional information rega
babelfishpg_tsql.explain_wal	off	Include information on WAL record g

(8 rows affected)

You can change the setting for these parameters using a `SELECT` statement with the PostgreSQL `set_config` function, as shown in the following example.

```
SELECT set_config('babelfishpg_tsql.explain_verbose', 'on', false);
```

For more information about `set_config`, see [Configuration Settings Functions](#) in the PostgreSQL documentation.

## Using Aurora PostgreSQL extensions with Babelfish

Aurora PostgreSQL provides extensions for working with other AWS services. These are optional extensions that support various use cases, such as using Amazon S3 with your DB cluster for importing or exporting data.

- To import data from an Amazon S3 bucket to your Babelfish DB cluster, you set up the `aws_s3` Aurora PostgreSQL extension. This extension also lets you export data from your Aurora PostgreSQL DB cluster to an Amazon S3 bucket.
- AWS Lambda is a compute service that lets you run code without provisioning or managing servers. You can use Lambda functions to do things like process event notifications from your DB instance. To learn more about Lambda, see [What is AWS Lambda?](#) in the *AWS Lambda Developer Guide*. To invoke Lambda functions from your Babelfish DB cluster, you set up the `aws_lambda` Aurora PostgreSQL extension.

To set up these extensions for your Babelfish cluster, you first need to grant permission to the internal Babelfish user to load the extensions. After granting permission, you can then load Aurora PostgreSQL extensions.

## Enabling Aurora PostgreSQL extensions in your Babelfish DB cluster

Before you can load the `aws_s3` or the `aws_lambda` extensions, you grant the needed privileges to your Babelfish DB cluster.

The procedure following uses the `psql` PostgreSQL command line tool to connect to the DB cluster. For more information, see [Using psql to connect to the DB cluster \(p. 1103\)](#). You can also use pgAdmin. For details, see [Using pgAdmin to connect to the DB cluster \(p. 1103\)](#).

This procedure loads both `aws_s3` and `aws_lambda`, one after the other. You don't need to load both if you want to use only one of these extensions. The `aws_commons` extension is required by each, and it's loaded by default as shown in the output.

### To set up your Babelfish DB cluster with privileges for the Aurora PostgreSQL extensions

1. Connect to your Babelfish DB cluster. Use the name for the "master" user (-U) that you specified when you created the Babelfish DB cluster. The default (`postgres`) is shown in the examples.

For Linux, macOS, or Unix:

```
psql -h your-Babelfish.cluster.444455556666-us-east-1.rds.amazonaws.com \
-U postgres \
-d babelfish_db \
-p 5432
```

For Windows:

```
psql -h your-Babelfish.cluster.444455556666-us-east-1.rds.amazonaws.com ^
-U postgres ^
-d babelfish_db ^
-p 5432
```

The command responds with a prompt to enter the password for the user name (-U).

```
Password:
```

Enter the password for the user name (-U) for the DB cluster. When you successfully connect, you see output similar to the following.

```
psql (13.4)
SSL connection (protocol: TLSv1.3, cipher: TLS_AES_256_GCM_SHA384, bits: 256,
compression: off)
Type "help" for help.

postgres=>
```

2. Grant privileges to the internal Babelfish user to create and load extensions.

```
babelfish_db=> GRANT rds_superuser TO master_dbo;
GRANT ROLE
```

3. Create and load the `aws_s3` extension. The `aws_commons` extension is required, and it's installed automatically when the `aws_s3` is installed.

```
babelfish_db=> create extension aws_s3 cascade;
NOTICE:  installing required extension "aws_commons"
CREATE EXTENSION
```

4. Create and load the aws\_lambda extension.

```
babelfish_db=> create extension aws_lambda cascade;
CREATE EXTENSION
babelfish_db=>
```

## Using Babelfish with Amazon S3

If you don't already have an Amazon S3 bucket to use with your Babelfish DB cluster, you can create one. For any Amazon S3 bucket that you want to use, you provide access.

Before trying to import or export data using an Amazon S3 bucket, complete the following one-time steps.

### To set up access for your Babelfish DB instance to your Amazon S3 bucket

1. Create an Amazon S3 bucket for your Babelfish instance, if needed. To do so, follow the instructions in [Create a bucket](#) in the *Amazon Simple Storage Service User Guide*.
2. Upload files to your Amazon S3 bucket. To do so, follow the steps in [Add an object to a bucket](#) in the *Amazon Simple Storage Service User Guide*.
3. Set up permissions as needed:
  - To import data from Amazon S3, the Babelfish DB cluster needs permission to access the bucket. We recommend using an AWS Identity and Access Management (IAM) role and attaching an IAM policy to that role for your cluster. To do so, follow the steps in [Using an IAM role to access an Amazon S3 bucket \(p. 1233\)](#).
  - To export data from your Babelfish DB cluster, your cluster must be granted access to the Amazon S3 bucket. As with importing, we recommend using an IAM role and policy. To do so, follow the steps in [Setting up access to an Amazon S3 bucket \(p. 1246\)](#).

You can now use Amazon S3 with the aws\_s3 extension with your Babelfish DB cluster.

### To import data from Amazon S3 to Babelfish and to export Babelfish data to Amazon S3

1. Use the aws\_s3 extension with your Babelfish DB cluster.

When you do, make sure to reference the tables as they exist in the context of PostgreSQL. That is, if you want to import into a Babelfish table named [ database ].[ schema ].[ tableA ], refer to that table as database\_schema\_tableA in the aws\_s3 function:

- For an example of using an aws\_s3 function to import data, see [Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster \(p. 1238\)](#).
  - For examples of using aws\_s3 functions to export data, see [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function \(p. 1249\)](#).
2. Make sure to reference Babelfish tables using PostgreSQL naming when using the aws\_s3 extension and Amazon S3, as shown in the following table.

Babelfish table	Aurora PostgreSQL table
<code>database.schema.table</code>	<code>database_schema_table</code>

To learn more about using Amazon S3 with Aurora PostgreSQL, see [Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster \(p. 1230\)](#) and [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3 \(p. 1243\)](#).

## Using Babelfish with AWS Lambda

After the `aws_lambda` extension is loaded in your Babelfish DB cluster but before you can invoke Lambda functions, you give Lambda access to your DB cluster by following this procedure.

### To set up access for your Babelfish DB cluster to work with Lambda

This procedure uses the AWS CLI to create the IAM policy and role, and associate these with the Babelfish DB cluster.

1. Create an IAM policy that allows access to Lambda from your Babelfish DB cluster.

```
aws iam create-policy --policy-name rds-lambda-policy --policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowAccessToExampleFunction",  
            "Effect": "Allow",  
            "Action": "lambda:InvokeFunction",  
            "Resource": "arn:aws:lambda:aws-region:444455556666:function:my-function"  
        }  
    ]  
}'
```

2. Create an IAM role that the policy can assume at runtime.

```
aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "rds.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}'
```

3. Attach the policy to the role.

```
aws iam attach-role-policy \  
    --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy \  
    --role-name rds-lambda-role --region aws-region
```

4. Attach the role to your Babelfish DB cluster

```
aws rds add-role-to-db-cluster \  
    --db-cluster-identifier my-cluster-name \  
    --feature-name Lambda \  
    --role-arn arn:aws:iam::444455556666:role/rds-lambda-role \  
    --region aws-region
```

After you complete these tasks, you can invoke your Lambda functions. For more information and examples of setting up AWS Lambda for Aurora PostgreSQL DB cluster with AWS Lambda, see [Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and AWS Lambda \(p. 1255\)](#).

## To invoke a Lambda function from your Babelfish DB cluster

AWS Lambda supports functions written in Java, Node.js, Python, Ruby, and other languages. If the function returns text when invoked, you can invoke it from your Babelfish DB cluster. The following example is a placeholder python function that returns a greeting.

```
lambda_function.py
import json
def lambda_handler(event, context):
    #TODO implement
    return {
        'statusCode': 200,
        'body': json.dumps('Hello from Lambda!')
```

Currently, Babelfish doesn't support JSON. If your function returns JSON, you use a wrapper to handle the JSON. For example, say that the `lambda_function.py` shown preceding is stored in Lambda as `my-function`.

1. Connect to your Babelfish DB cluster using the `psql` client (or the `pgAdmin` client). For more information, see [Using psql to connect to the DB cluster \(p. 1103\)](#).
2. Create the wrapper. This example uses PostgreSQL's procedural language for SQL, `PL/pgSQL`. To learn more, see [PL/pgSQL—SQL Procedural Language](#).

```
create or replace function master_dbo.lambda_wrapper()
returns text
language plpgsql
as
$$
declare
    r_status_code integer;
    r_payload text;
begin
    SELECT payload INTO r_payload
    FROM aws_lambda.invoke(  aws_commons.create_lambda_function_arn('my-function',
    'us-east-1')
                                , '{"body": "Hello from Postgres!"}':json );
    return r_payload ;
end;
$$;
```

The function can now be run from the Babelfish TDS port (1433) or from the PostgreSQL port (5433).

- a. To invoke (call) this function from your PostgreSQL port:

```
SELECT * from aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-
function', 'us-east-1'), '{"body": "Hello from Postgres!"}':json );
```

The output is similar to the following:

status_code	payload
executed_version   log_result	
-----+-----	
200   {"statusCode": 200, "body": "\"Hello from Lambda!\""}   \$LATEST	
(1 row)	

- 
- b. To invoke (call) this function from the TDS port, connect to the port using the SQL Server `sqlcmd` command line client. For details, see [Using a SQL Server client to connect to your DB cluster \(p. 1100\)](#). When connected, run the following:

```
1> select lambda_wrapper();
2> go
```

The command returns output similar to the following:

```
{"statusCode": 200, "body": "\"Hello from Lambda!\""}

---

```

To learn more about using Lambda with Aurora PostgreSQL, see [Invoking an AWS Lambda function from an Aurora PostgreSQL DB cluster \(p. 1254\)](#). For more information about working with Lambda functions, see [Getting started with Lambda](#) in the *AWS Lambda Developer Guide*.

## Troubleshooting Babelfish

Following, you can find troubleshooting ideas and workarounds for some Babelfish DB cluster issues.

### Topics

- [Connection failure \(p. 1123\)](#)
- [Using pg\\_dump and pg\\_restore requires extra setup \(p. 1123\)](#)

## Connection failure

Common causes of connection failures to a new Aurora DB cluster with Babelfish include the following:

- **Security group doesn't allow access** – If you're having trouble connecting to a Babelfish, make sure that you added your IP address to the default Amazon EC2 security group. You can use <https://checkip.amazonaws.com/> to determine your IP address and then add it to your in-bound rule for the TDS port and the PostgreSQL port. For more information, see [Add rules to a security group](#) in the *Amazon EC2 User Guide*.
- **Mismatching SSL configurations** – If the `rds.force_ssl` parameter is turned on (set to 1) on Aurora PostgreSQL, then clients must connect to Babelfish over SSL. If your client isn't set up correctly, you see an error message such as the following:

```
Cannot connect to your-Babelfish-DB-cluster, 1433
-----
ADDITIONAL INFORMATION:
no pg_hba.conf entry for host "256.256.256.256", user "your-user-name",
"database babelfish_db", SSL off (Microsoft SQL Server, Error: 33557097)
...
```

This error indicates a possible SSL configuration issue between your local client and the Babelfish DB cluster, and that the cluster requires clients to use SSL (its `rds.force_ssl` parameter is set to 1). For more information about configuring SSL, see [Using SSL with a PostgreSQL DB instance](#) in the *Amazon RDS User Guide*.

If you are using SQL Server Management Studio (SSMS) to connect to Babelfish and you see this error, you can choose **Encrypt connection** and **Trust server certificate** connection options on the Connection Properties pane and try again. These settings handle the SSL connection requirement for SSMS.

For more information about troubleshooting Aurora connection issues, see [Can't connect to Amazon RDS DB instance \(p. 1761\)](#).

## Using pg\_dump and pg\_restore requires extra setup

Currently, if you try to use the PostgreSQL utilities `pg_dump` and `pg_restore` to move a database from one Babelfish DB cluster to another, you see the following error message.

```
psql:bbf.sql:29: ERROR:  role "db_owner" does not exist
psql:bbf.sql:49: ERROR:  role "dbo" does not exist
```

To work around this issue, first create the same logical database on the target cluster that is on the source. After that exists, you can create the needed roles to run `pg_dump` and `pg_restore`.

### To use pg\_dump and pg\_restore to move a database between Babelfish DB clusters

1. Connect to your SQL Server endpoint using SQL Server Management Studio (SSMS).

2. Create the same logical database on your target that is on your source. To restore multiple databases, make sure to create those in advance.

```
CREATE DATABASE your-DB-name
```

3. Use pg\_restore to restore the DB instance from the source to the target.

To learn more about using these PostgreSQL utilities, see [pg\\_dump](#) and [pg\\_restore](#) in the PostgreSQL documentation.

## Turning off Babelfish

When you no longer need Babelfish, you can turn off Babelfish functionality.

Be aware of some considerations:

- In some cases, you might turn off Babelfish before completing a migration to Aurora PostgreSQL. If you do and your DDL depends on SQL Server data types or you use any T-SQL functionality in your code, your code fails.
- If after provisioning a Babelfish instance you turn off the Babelfish extension, you can't provision that same database again on the same cluster.

To turn off Babelfish, modify your parameter group, setting `rds.babelfish_status` to `OFF`. You can continue to use your SQL Server data types with Babelfish off, by setting `rds.babelfish_status` to `datatypeonly`.

If you turn off Babelfish in parameter group, all clusters that use that parameter group lose Babelfish functionality.

For more information about modifying parameter groups, see [Working with parameter groups \(p. 215\)](#). For information about Babelfish-specific parameters, see [DB cluster parameter group settings for Babelfish \(p. 1068\)](#).

## Babelfish version updates

Babelfish is an option available with Aurora PostgreSQL version 13.4 and higher releases. Updates to Babelfish become available with certain new releases of the Aurora PostgreSQL database engine. For more information, see the [Release Notes for Aurora PostgreSQL](#).

For a list of supported functionality across different Babelfish releases, see [Supported functionality in Babelfish by version \(p. 1137\)](#).

For a list of currently unsupported functionality, see [Unsupported functionality in Babelfish \(p. 1128\)](#).

**Note**

Currently, you can't upgrade Babelfish DB clusters running on Aurora PostgreSQL 13.7 or older versions to Aurora PostgreSQL 14.3 with Babelfish 2.1.0.

## Identifying your version of Babelfish

You can query Babelfish to find details about the Babelfish version, the Aurora PostgreSQL version, and the compatible Microsoft SQL Server version. You can use the TDS port or the PostgreSQL port.

### To use the TDS port to query for version information

1. Use `sqlcmd` or `ssms` to connect to the endpoint for your Babelfish DB cluster.

```
sqlcmd -S bfish_db.cluster-123456789012.aws-region.rds.amazonaws.com,1433 -U  
        login-id -P password -d db_name
```

2. To identify the Babelfish version, run the following query:

```
1> SELECT CAST(serverproperty('babelfishversion') AS VARCHAR)  
2> GO
```

The query returns results similar to the following:

```
serverproperty  
-----  
2.1.0  
  
(1 rows affected)
```

3. To identify the version of the Aurora PostgreSQL DB cluster, run the following query:

```
1> SELECT aurora_version() AS aurora_version  
2> GO
```

The query returns results similar to the following:

```
aurora_version  
  
-----  
14.3.0  
  
(1 rows affected)
```

4. To identify the compatible Microsoft SQL Server version, run the following query:

```
1> SELECT @@VERSION AS version
```

```
2> GO
```

The query returns results similar to the following:

```
Babelfish for Aurora PostgreSQL with SQL Server Compatibility - 12.0.2000.8
May 23 2022 19:17:14
Copyright (c) Amazon Web Services
PostgreSQL 14.3 on x86_64-pc-linux-gnu

(1 rows affected)
```

As an example that shows one minor difference between Babelfish and Microsoft SQL Server, you can run the following query. On Babelfish, the query returns 1, while on Microsoft SQL Server, the query returns NULL.

```
SELECT CAST(serverproperty('babelfish') AS VARCHAR) AS runs_on_babelfish
```

You can also use the PostgreSQL port to obtain version information, as shown in the following procedure.

### To use the PostgreSQL port to query for version information

1. Use psql or pgAdmin to connect to the endpoint for your Babelfish DB cluster.

```
psql host=bfish_db.cluster-123456789012.aws-region.rds.amazonaws.com
port=5432 dbname=babelfish_db user=sa
```

2. Turn on the extended feature (\x) of psql for more readable output.

```
babelfish_db=> \x
babelfish_db=> SELECT
babelfish_db=> aurora_version() AS aurora_version,
babelfish_db=> version() AS postgresql_version,
babelfish_db=> sys.version() AS Babelfish_compatibility,
babelfish_db=> sys.SERVERPROPERTY('BabelfishVersion') AS Babelfish_Version;
```

The query returns output similar to the following:

```
-[ RECORD 1 ]-----
aurora_version      | 14.3.0
postgresql_version   | PostgreSQL 14.3 on x86_64-pc-linux-gnu, compiled by x86_64-
pc-linux-gnu-gcc (GCC) 7.4.0, 64-bit
babelfish_compatibility | Babelfish for Aurora Postgres with SQL Server Compatibility -
12.0.2000.8
                           +
                           | May 23 2022 19:17:14
                           +
                           | Copyright (c) Amazon Web Services
                           +

- [Supported functionality in Babelfish by version \(p. 1137\)](#)

## Unsupported functionality in Babelfish

In the following table and lists, you can find functionality that isn't currently supported in Babelfish. Updates to Babelfish are included in Aurora PostgreSQL versions. For more information, see the [Release Notes for Aurora PostgreSQL](#).

## Topics

- [Functionality that isn't currently supported \(p. 1128\)](#)
- [Settings that aren't supported \(p. 1131\)](#)
- [Commands that aren't supported \(p. 1131\)](#)
- [Column names or attributes that aren't supported \(p. 1131\)](#)
- [Object types that aren't supported \(p. 1131\)](#)
- [Functions that aren't supported \(p. 1132\)](#)
- [Syntax that isn't supported \(p. 1133\)](#)

## Functionality that isn't currently supported

In the table you can find information about certain functionality that isn't currently supported.

Functionality or syntax	Description
Assembly modules and SQL Common Language Runtime (CLR) routines	Functionality related to assembly modules and CLR routines isn't supported.
Column attributes	ROWGUIDCOL, SPARSE, FILESTREAM, and MASKED aren't supported.
Contained databases	Contained databases with logins authenticated at the database level rather than at the server level aren't supported.
CROSS APPLY	Lateral joins aren't supported.
Cursors (updatable)	Updatable cursors aren't supported.
Cursors (global)	GLOBAL cursors aren't supported.
Cursor (fetch behaviors)	The following cursor fetch behaviors aren't supported: FETCH PRIOR, FIRST, LAST, ABSOLUTE, and RELATIVE
Cursor-typed (variables and parameters)	Cursor-typed variables and parameters aren't supported for output parameters (an error is raised).
Cursor options	SCROLL, KEYSET, DYNAMIC, FAST_FORWARD, SCROLL_LOCKS, OPTIMISTIC, TYPE_WARNING, and FOR UPDATE
Data encryption	Data encryption isn't supported.

Functionality or syntax	Description
DBCC commands	Microsoft SQL Server Database Console Commands (DBCC) aren't supported.
DROP IF EXISTS	This syntax isn't supported for USER and SCHEMA objects. It's supported for the objects TABLE, VIEW, PROCEDURE, FUNCTION, and DATABASE.
Encryption	Built-in functions and statements don't support encryption.
ENCRYPT_CLIENT_CERT connections	Client certificate connections aren't supported.
EXECUTE AS statement	This statement isn't supported.
EXECUTE AS SELF clause	This clause isn't supported in functions, procedures, or triggers.
EXECUTE AS USER clause	This clause isn't supported in functions, procedures, or triggers.
Foreign key constraints referencing database name	Foreign key constraints that reference the database name aren't supported.
Full-text search	Full-text search built-in Functions and statements aren't supported.
Function declarations with greater than 100 parameters	Function declarations that contain more than 100 parameters aren't supported.
Function calls that include DEFAULT as a parameter value	DEFAULT isn't a supported parameter value for a function call.
Function calls that include ::	Function calls that include :: aren't supported.
Functions, externally defined	External functions, including SQL CLR functions, aren't supported.
Global temporary tables (tables with names that start with ##)	Global temporary tables aren't supported.
Graph functionality	All SQL graph functionality isn't supported.
Hints	Hints aren't supported for joins, queries, or tables.
Identifiers (variables or parameters) with multiple leading @ characters	Identifiers that start with more than one leading @ aren't supported.
Identifiers, table or column names that contain @ or ]] characters	Table or column names that contain an @ sign or square brackets aren't supported.
Inline indexes	Inline indexes aren't supported.
Invoking a procedure whose name is in a variable	Using a variable as a procedure name isn't supported.
JSON_MODIFY	Updating JSON string using JSON_MODIFY isn't supported.
FOR JSON clause	Formatting query results as JSON isn't supported.
Materialized views	Materialized views aren't supported.
NOT FOR REPLICATION clause	This syntax is accepted and ignored.

Functionality or syntax	Description
ODBC escape functions	ODBC escape functions aren't supported.
Partitioning	Table and index partitioning isn't supported.
Procedure calls that includes DEFAULT as a parameter value	DEFAULT isn't a supported parameter value.
Procedure declarations with more than 100 parameters	Declarations with more than 100 parameters aren't supported.
Procedures, externally defined	Externally defined procedures, including SQL CLR procedures, aren't supported.
Procedure versioning	Procedure versioning isn't supported.
Procedures WITH RECOMPILE	WITH RECOMPILE (when used in conjunction with the DECLARE and EXECUTE statements) isn't supported.
Remote object references	Objects with four-part names aren't supported.. For more information, see: <a href="#">DB cluster parameter group settings for Babelfish (p. 1068)</a> .
Row-level security	Row-level security with CREATE SECURITY POLICY and inline table-valued functions isn't supported.
Service broker functionality	Service broker functionality isn't supported.
SESSIONPROPERTY	Unsupported properties: ANSI_NULLS, ANSI_PADDING, ANSI_WARNINGS, ARITHABORT, CONCAT_NULL_YIELDS_NULL, and NUMERIC_ROUNDABORT
SET LANGUAGE	This syntax isn't supported with any value other than english or us_english.
SP_CONFIGURE	This system stored procedure isn't supported.
SQL keyword SPARSE	The keyword SPARSE is accepted and ignored.
Table value constructor syntax (FROM clause)	The unsupported syntax is for a derived table constructed with the FROM clause.
Temporal tables	Temporal tables aren't supported.
Temporary procedures aren't dropped automatically	This functionality isn't supported.
Transaction isolation levels	READUNCOMMITTED is treated the same as READCOMMITTED. REPEATABLEREAD, and SERIALIZABLE aren't supported.
Triggers, externally defined	These triggers aren't supported, including SQL Common Language Runtime (CLR).
Triggers, INSTEAD-OF on views	INSTEAD-OF triggers on views aren't supported. INSTEAD-OF triggers are supported (Babelfish 1.2.0 and higher releases).
Unquoted string values in stored procedure calls and default values	String parameters to stored procedure calls, and defaults for string parameters in CREATE PROCEDURE, aren't supported.

Functionality or syntax	Description
WITHOUT SCHEMABINDING clause	This clause isn't supported in functions, procedures, triggers, or views. The object is created, but as if WITH SCHEMABINDING was specified.

## Settings that aren't supported

The following settings aren't supported:

- SET ANSI\_NULL\_DFLT\_OFF ON
- SET ANSI\_NULL\_DFLT\_ON OFF
- SET ANSI\_PADDING OFF
- SET ANSI\_WARNINGS OFF
- SET ARITHABORT OFF
- SET ARITHIGNORE ON
- SET CURSOR\_CLOSE\_ON\_COMMIT ON
- SET NUMERIC\_ROUNDABORT ON
- SET PARSEONLY ON (command doesn't work as expected)

## Commands that aren't supported

Certain functionality for the following commands isn't supported:

- ADD SIGNATURE
- ALTER DATABASE, ALTER DATABASE SET
- CREATE, ALTER, DROP AUTHORIZATION
- CREATE, ALTER, DROP AVAILABILITY GROUP
- CREATE, ALTER, DROP BROKER PRIORITY
- CREATE, ALTER, DROP COLUMN ENCRYPTION KEY
- CREATE, ALTER, DROP DATABASE ENCRYPTION KEY
- CREATE, ALTER, DROP BACKUP CERTIFICATE
- CREATE AGGREGATE
- CREATE CONTRACT
- GRANT

## Column names or attributes that aren't supported

The following column names aren't supported:

- \$IDENTITY
- \$ROWGUID
- IDENTITYCOL

## Object types that aren't supported

The following object types aren't supported:

- COLUMN MASTER KEY

- CREATE, ALTER EXTERNAL DATA SOURCE
- CREATE, ALTER, DROP DATABASE AUDIT SPECIFICATION
- CREATE, ALTER, DROP EXTERNAL LIBRARY
- CREATE, ALTER, DROP SERVER AUDIT
- CREATE, ALTER, DROP SERVER AUDIT SPECIFICATION
- CREATE, ALTER, DROP, OPEN/CLOSE SYMMETRIC KEY
- CREATE, DROP DEFAULT
- CREDENTIAL
- CRYPTOGRAPHIC PROVIDER
- DIAGNOSTIC SESSION
- Indexed views
- SERVICE MASTER KEY
- SYNONYM

## Functions that aren't supported

The following built-in functions aren't supported:

### Aggregate functions

- APPROX\_COUNT\_DISTINCT
- CHECKSUM\_AGG
- GROUPING\_ID
- ROWCOUNT\_BIG
- STDEV
- STDEVP
- VAR
- VARP

### Cryptographic functions

- CERTENCODED function
- CERTID function
- CERTPROPERTY function

### Metadata functions

- COLUMNPROPERTY
- OBJECTPROPERTY
- OBJECTPROPERTYEX
- TYPEPROPERTY
- SERVERPROPERTY function – The following properties aren't supported:
  - BuildClrVersion
  - ComparisonStyle
  - ComputerNamePhysicalNetBIOS
  - HadrManagerStatus
  - InstanceDefaultDataPath

- InstanceDefaultLogPath
- InstanceName
- IsClustered
- IsHadrEnabled
- LCID
- MachineName
- NumLicenses
- ProcessID
- ProductBuild
- ProductBuildType
- ProductLevel
- ProductUpdateLevel
- ProductUpdateReference
- ResourceLastUpdateDateTime
- ResourceVersion
- ServerName
- SqlCharSet
- SqlCharSetName
- SqlSortOrder
- SqlSortOrderName
- FilestreamShareName
- FilestreamConfiguredLevel
- FilestreamEffectiveLevel

## Security functions

- CERTPRIVATEKEY
- LOGINPROPERTY

## Statements, operators, other functions

- EVENTDATA function
- GET\_TRANSMISSION\_STATUS
- OPENXML

## Syntax that isn't supported

The following syntax isn't supported:

- ALTER DATABASE
- ALTER DATABASE SCOPED CONFIGURATION
- ALTER DATABASE SCOPED CREDENTIAL
- ALTER DATABASE SET HADR
- ALTER FUNCTION
- ALTER INDEX
- ALTER PROCEDURE statement
- ALTER SCHEMA

- ALTER SERVER CONFIGURATION
- ALTER SERVICE, BACKUP/RESTORE SERVICE MASTER KEY clause
- ALTER VIEW
- BEGIN CONVERSATION TIMER
- BEGIN DISTRIBUTED TRANSACTION
- BEGIN DIALOG CONVERSATION
- BULK INSERT
- CREATE COLUMNSTORE INDEX
- CREATE EXTERNAL FILE FORMAT
- CREATE EXTERNAL TABLE
- CREATE, ALTER, DROP APPLICATION ROLE
- CREATE, ALTER, DROP ASSEMBLY
- CREATE, ALTER, DROP ASYMMETRIC KEY
- CREATE, ALTER, DROP CREDENTIAL
- CREATE, ALTER, DROP CRYPTOGRAPHIC PROVIDER
- CREATE, ALTER, DROP ENDPOINT
- CREATE, ALTER, DROP EVENT SESSION
- CREATE, ALTER, DROP EXTERNAL LANGUAGE
- CREATE, ALTER, DROP EXTERNAL RESOURCE POOL
- CREATE, ALTER, DROP FULLTEXT CATALOG
- CREATE, ALTER, DROP FULLTEXT INDEX
- CREATE, ALTER, DROP FULLTEXT STOPLIST
- CREATE, ALTER, DROP MESSAGE TYPE
- CREATE, ALTER, DROP OPEN/CLOSE, BACKUP/RESTORE MASTER KEY
- CREATE, ALTER, DROP PARTITION FUNCTION
- CREATE, ALTER, DROP PARTITION SCHEME
- CREATE, ALTER, DROP QUEUE
- CREATE, ALTER, DROP RESOURCE GOVERNOR
- CREATE, ALTER, DROP RESOURCE POOL
- CREATE, ALTER, DROP ROUTE
- CREATE, ALTER, DROP SEARCH PROPERTY LIST
- CREATE, ALTER, DROP SECURITY POLICY
- CREATE, ALTER, DROP SELECTIVE XML INDEX clause
- CREATE, ALTER, DROP SERVICE
- CREATE, ALTER, DROP SPATIAL INDEX
- CREATE, ALTER, DROP TYPE
- CREATE, ALTER, DROP XML INDEX
- CREATE, ALTER, DROP XML SCHEMA COLLECTION
- CREATE/DROP RULE
- CREATE, DROP WORKLOAD CLASSIFIER
- CREATE, ALTER, DROP WORKLOAD GROUP
- CREATE/ALTER/ENABLE/DISABLE TRIGGER
- CREATE TABLE... GRANT clause
- CREATE TABLE... IDENTITY clause

- CREATE USER – This syntax isn't supported. The PostgreSQL statement CREATE USER doesn't create a user that is equivalent to the SQL Server CREATE USER syntax. For more information, see [T-SQL differences in Babelfish \(p. 1109\)](#).
- DENY
- END, MOVE CONVERSATION
- EXECUTE with AS LOGIN or AT option
- GET CONVERSATION GROUP
- GROUP BY ALL clause
- GROUP BY CUBE clause
- GROUP BY ROLLUP clause
- INSERT... DEFAULT VALUES
- INSERT... TOP
- KILL
- MERGE
- NEXT VALUE FOR sequence clause
- READTEXT
- REVERT
- REVOKE
- SELECT PIVOT/UNPIVOT
- SELECT TOP x PERCENT WHERE x <> 100
- SELECT TOP... WITH TIES
- SELECT... FOR BROWSE
- SELECT... FOR XML AUTO
- SELECT... FOR XML EXPLICIT
- SEND
- SET CONTEXT\_INFO
- SET DATEFORMAT
- SET DEADLOCK\_PRIORITY
- SET FMTONLY
- SET FORCEPLAN
- SET NO\_BROWSETABLE
- SET NUMERIC\_ROUNDABORT ON
- SET OFFSETS
- SET REMOTE\_PROC\_TRANSACTIONS
- SET ROWCOUNT @variable
- SET ROWCOUNT n WHERE n != 0
- SET SHOWPLAN\_ALL
- SET SHOWPLAN\_TEXT
- SET SHOWPLAN\_XML
- SET STATISTICS
- SET STATISTICS IO
- SET STATISTICS PROFILE
- SET STATISTICS TIME
- SET STATISTICS XML
- SET TRANSACTION ISOLATION LEVEL REPEATABLE READ
- SET TRANSACTION ISOLATION LEVEL SERIALIZABLE

- SHUTDOWN statement
- UPDATE STATISTICS
- UPDATERETEXT
- Using EXECUTE to call a SQL function
- VIEW... CHECK OPTION clause
- VIEW... VIEW\_METADATA clause
- WAITFOR DELAY
- WAITFOR TIME
- WAITFOR, RECEIVE
- WITH XMLNAMESPACES construct
- WRITETEXT
- XPATH expressions

## Supported functionality in Babelfish by version

In the following table you can find T-SQL functionality supported by different Babelfish versions. For lists of unsupported functionality, see [Unsupported functionality in Babelfish \(p. 1128\)](#). For information about various Babelfish releases, see the [Release Notes for Aurora PostgreSQL](#).

Functionality or syntax	2.1.0	1.2.1	1.1.0	1.0.0
ALTER ROLE	✓	–	–	–

## Managing Amazon Aurora PostgreSQL

The following section discusses managing performance and scaling for an Amazon Aurora PostgreSQL DB cluster. It also includes information about other maintenance tasks.

### Topics

- [Scaling Aurora PostgreSQL DB instances \(p. 1143\)](#)
- [Maximum connections to an Aurora PostgreSQL DB instance \(p. 1144\)](#)
- [Temporary storage limits for Aurora PostgreSQL \(p. 1146\)](#)
- [Testing Amazon Aurora PostgreSQL by using fault injection queries \(p. 1147\)](#)
- [Displaying volume status for an Aurora PostgreSQL DB cluster \(p. 1151\)](#)
- [Specifying the RAM disk for the stats\\_temp\\_directory \(p. 1152\)](#)

## Scaling Aurora PostgreSQL DB instances

You can scale Aurora PostgreSQL DB instances in two ways, instance scaling and read scaling. For more information about read scaling, see [Read scaling \(p. 278\)](#).

You can scale your Aurora PostgreSQL DB cluster by modifying the DB instance class for each DB instance in the DB cluster. Aurora PostgreSQL supports several DB instance classes optimized for Aurora. Don't use db.t2 or db.t3 instance classes for larger Aurora clusters of size greater than 40 terabytes (TB).

Scaling isn't instantaneous. It can take 15 minutes or more to complete the change to a different DB instance class. We recommend that if you use this approach to modify the DB instance class, you apply the change during the next scheduled maintenance window (rather than immediately) to avoid affecting users.

As an alternative to modifying the DB instance class directly, you can minimize downtime by using the high availability features of Amazon Aurora. First, add an Aurora Replica to your cluster. When creating the replica, choose the DB instance class size that you want to use for your cluster. When the Aurora Replica is synchronized with the cluster, you then failover to the newly added Replica. To learn more, see [Aurora Replicas \(p. 73\)](#) and [Fast failover with Amazon Aurora PostgreSQL \(p. 1201\)](#).

For detailed specifications of the DB instance classes supported by Aurora PostgreSQL, see [Supported DB engines for DB instance classes \(p. 57\)](#).

## Maximum connections to an Aurora PostgreSQL DB instance

An Aurora PostgreSQL DB cluster allocates resources based on the DB instance class and its available memory. Each connection to the DB cluster consumes incremental amounts of these resources, such as memory and CPU. Memory consumed per connection varies based on query type, count, and whether temporary tables are used. Even an idle connection consumes memory and CPU. That's because when queries run on a connection, more memory is allocated for each query and it's not released completely, even when processing stops. Thus, we recommend that you make sure your applications aren't holding on to idle connections: each one of these wastes resources and affects performance negatively. For more information, see [Resources consumed by idle PostgreSQL connections](#).

The maximum number of connections allowed by an Aurora PostgreSQL DB instance is determined by the `max_connections` parameter value specified in the parameter group for that DB instance. The ideal setting for the `max_connections` parameter is one that supports all the client connections your application needs, without an excess of unused connections, plus at least 3 more connections to support AWS automation. Before modifying the `max_connections` parameter setting, we recommend that you consider the following:

- If the `max_connections` value is too low, the Aurora PostgreSQL DB instance might not have sufficient connections available when clients attempt to connect. If this happens, attempts to connect using `psql` raise error messages such as the following:

```
psql: FATAL: remaining connection slots are reserved for non-replication superuser connections
```

- If the `max_connections` value exceeds the number of connections that are actually needed, the unused connections can cause performance to degrade.

The value of `max_connections` is derived from the following Aurora PostgreSQL `LEAST` function:

```
LEAST({DBInstanceClassMemory/9531392}, 5000)
```

If you want to change the value for `max_connections`, you need to create a custom DB cluster parameter group and change its value there. After applying your custom DB parameter group to your cluster, be sure to reboot the primary instance so the new value takes effect. For more information, see [Amazon Aurora PostgreSQL parameters \(p. 1369\)](#) and [Creating a DB cluster parameter group \(p. 219\)](#).

Following, you can find a table that lists the highest value that should ever be used for `max_connections` for each DB instance class that can be used with Aurora PostgreSQL. If your

application needs more connections than the number listed for your DB instance class, consider the following alternatives:

- Choose a DB instance class that has more memory. If your connection requirements are too high for the DB instance class supporting your Aurora PostgreSQL DB cluster, you can potentially overload your database and decrease performance. For list of DB instance classes for Aurora PostgreSQL, see [Supported DB engines for DB instance classes \(p. 57\)](#). For the amount of memory for each DB instance class, [Hardware specifications for DB instance classes for Aurora \(p. 64\)](#).
- Pool connections by using RDS Proxy with your Aurora PostgreSQL DB cluster. For more information, see [Using Amazon RDS Proxy \(p. 1430\)](#).

For details about how Aurora Serverless v2 instances handle this parameter, see [Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity \(p. 1537\)](#).

Instance class	Default max_connections value
db.x2g.16xlarge	5000
db.x2g.12xlarge	5000

db.t3.medium	420

## Temporary storage limits for Aurora PostgreSQL

Aurora PostgreSQL stores tables and indexes in the Aurora storage subsystem. Aurora PostgreSQL uses separate temporary storage for non-persistent temporary files. This includes files that are used for such purposes as sorting large data sets during query processing or for index build operations. These local storage volumes are backed by Amazon Elastic Block Store and can be extended. For more information about storage, see [Amazon Aurora storage and reliability \(p. 67\)](#).

The following table shows the maximum amount of temporary storage available for each Aurora PostgreSQL DB instance class.

DB instance class	Maximum temporary storage available (GiB)
db-x2g-16xlarge	1829
db-x2g-12xlarge	1606
db-x2g-8xlarge	1071
db-x2g-4xlarge	535
db-x2g-2xlarge	268
db-x2g-xlarge	134
db-x2g-large	67
db.r6g.16xlarge	1008
db.r6g.12xlarge	756
db.r6g.8xlarge	504
db.r6g.4xlarge	252
db.r6g.2xlarge	126
db.r6g.xlarge	63
db.r6g.large	32

DB instance class	Maximum temporary storage available (GiB)
db.r5.24xlarge	1500
db.r5.16xlarge	1008
db.r5.12xlarge	748
db.r5.8xlarge	504
db.r5.4xlarge	249
db.r5.2xlarge	124
db.r5.xlarge	62
db.r5.large	31
db.r4.16xlarge	960
db.r4.8xlarge	480
db.r4.4xlarge	240
db.r4.2xlarge	120
db.r4.xlarge	60
db.r4.large	30
db.t4g.large	16.5
db.t4g.medium	8.13
db.t3.large	16
db.t3.medium	7.5

You can monitor the temporary storage available for a DB instance with the `FreeLocalStorage` CloudWatch metric, described in [Amazon CloudWatch metrics for Amazon Aurora \(p. 525\)](#). (This doesn't apply to Aurora Serverless v2.)

For some workloads, you can reduce the amount of temporary storage by allocating more memory to the processes that are performing the operation. To increase the memory available to an operation, increasing the values of the `work_mem` or `maintenance_work_mem` PostgreSQL parameters.

## Testing Amazon Aurora PostgreSQL by using fault injection queries

You can test the fault tolerance of your Aurora PostgreSQL DB cluster by using fault injection queries. Fault injection queries are issued as SQL commands to an Amazon Aurora instance. Fault injection queries let you crash the instance so that you can test failover and recovery. You can also simulate Aurora Replica failure, disk failure, and disk congestion. Fault injection queries are supported by all available Aurora PostgreSQL versions, as follows.

- Aurora PostgreSQL versions 12, 13, 14, and higher
- Aurora PostgreSQL version 11.7 and higher
- Aurora PostgreSQL version 10.11 and higher

## Topics

- [Testing an instance crash \(p. 1148\)](#)
- [Testing an Aurora Replica failure \(p. 1148\)](#)
- [Testing a disk failure \(p. 1149\)](#)
- [Testing disk congestion \(p. 1150\)](#)

When a fault injection query specifies a crash, it forces a crash of the Aurora PostgreSQL DB instance. The other fault injection queries result in simulations of failure events, but don't cause the event to occur. When you submit a fault injection query, you also specify an amount of time for the failure event simulation to occur.

You can submit a fault injection query to one of your Aurora Replica instances by connecting to the endpoint for the Aurora Replica. For more information, see [Amazon Aurora connection management \(p. 35\)](#).

## Testing an instance crash

You can force a crash of an Aurora PostgreSQL instance by using the fault injection query function `aurora_inject_crash()`.

For this fault injection query, a failover does not occur. If you want to test a failover, then you can choose the **Failover** instance action for your DB cluster in the RDS console, or use the `failover-db-cluster` AWS CLI command or the `FailoverDBCluster` RDS API operation.

### Syntax

```
SELECT aurora_inject_crash ('instance' | 'dispatcher' | 'node');
```

### Options

This fault injection query takes one of the following crash types. The crash type is not case sensitive:

*'instance'*

A crash of the PostgreSQL-compatible database for the Amazon Aurora instance is simulated.

*'dispatcher'*

A crash of the dispatcher on the primary instance for the Aurora DB cluster is simulated. The *dispatcher* writes updates to the cluster volume for an Amazon Aurora DB cluster.

*'node'*

A crash of both the PostgreSQL-compatible database and the dispatcher for the Amazon Aurora instance is simulated.

## Testing an Aurora Replica failure

You can simulate the failure of an Aurora Replica by using the fault injection query function `aurora_inject_replica_failure()`.

An Aurora Replica failure blocks replication to the Aurora Replica or all Aurora Replicas in the DB cluster by the specified percentage for the specified time interval. When the time interval completes, the affected Aurora Replicas are automatically synchronized with the primary instance.

### Syntax

```
SELECT aurora_inject_replica_failure(  
    percentage_of_failure,  
    time_interval,  
    'replica_name'  
) ;
```

## Options

This fault injection query takes the following parameters:

*percentage\_of\_failure*

The percentage of replication to block during the failure event. This value can be a double between 0 and 100. If you specify 0, then no replication is blocked. If you specify 100, then all replication is blocked.

*time\_interval*

The amount of time to simulate the Aurora Replica failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

### Note

Take care when specifying the time interval for your Aurora Replica failure event. If you specify too long an interval, and your writer instance writes a large amount of data during the failure event, then your Aurora DB cluster might assume that your Aurora Replica has crashed and replace it.

*replica\_name*

The Aurora Replica in which to inject the failure simulation. Specify the name of an Aurora Replica to simulate a failure of the single Aurora Replica. Specify an empty string to simulate failures for all Aurora Replicas in the DB cluster.

To identify replica names, see the `server_id` column from the `aurora_replica_status()` function. For example:

```
postgres=> SELECT server_id FROM aurora_replica_status();
```

## Testing a disk failure

You can simulate a disk failure for an Aurora PostgreSQL DB cluster by using the fault injection query function `aurora_inject_disk_failure()`.

During a disk failure simulation, the Aurora PostgreSQL DB cluster randomly marks disk segments as faulting. Requests to those segments are blocked for the duration of the simulation.

## Syntax

```
SELECT aurora_inject_disk_failure(  
    percentage_of_failure,  
    index,  
    is_disk,  
    time_interval  
) ;
```

## Options

This fault injection query takes the following parameters:

*percentage\_of\_failure*

The percentage of the disk to mark as faulting during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as faulting. If you specify 100, then the entire disk is marked as faulting.

*index*

A specific logical block of data in which to simulate the failure event. If you exceed the range of available logical blocks or storage nodes data, you receive an error that tells you the maximum index value that you can specify. To avoid this error, see [Displaying volume status for an Aurora PostgreSQL DB cluster \(p. 1151\)](#).

*is\_disk*

Indicates whether the injection failure is to a logical block or a storage node. Specifying true means injection failures are to a logical block. Specifying false means injection failures are to a storage node.

*time\_interval*

The amount of time to simulate the Aurora Replica failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

## Testing disk congestion

You can simulate a disk failure for an Aurora PostgreSQL DB cluster by using the fault injection query function `aurora_inject_disk_congestion()`.

During a disk congestion simulation, the Aurora PostgreSQL DB cluster randomly marks disk segments as congested. Requests to those segments are delayed between the specified minimum and maximum delay time for the duration of the simulation.

### Syntax

```
SELECT aurora_inject_disk_congestion(  
    percentage_of_failure,  
    index,  
    is_disk,  
    time_interval,  
    minimum,  
    maximum  
)
```

### Options

This fault injection query takes the following parameters:

*percentage\_of\_failure*

The percentage of the disk to mark as congested during the failure event. This is a double value between 0 and 100. If you specify 0, then none of the disk is marked as congested. If you specify 100, then the entire disk is marked as congested.

*index*

A specific logical block of data or storage node to use to simulate the failure event.

If you exceed the range of available logical blocks or storage nodes of data, you receive an error that tells you the maximum index value that you can specify. To avoid this error, see [Displaying volume status for an Aurora PostgreSQL DB cluster \(p. 1151\)](#).

*is\_disk*

Indicates whether the injection failure is to a logical block or a storage node. Specifying true means injection failures are to a logical block. Specifying false means injection failures are to a storage node.

*time\_interval*

The amount of time to simulate the Aurora Replica failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

*minimum, maximum*

The minimum and maximum amount of congestion delay, in milliseconds. Valid values range from 0.0 to 100.0 milliseconds. Disk segments marked as congested are delayed for a random amount of time within the minimum and maximum range for the duration of the simulation. The maximum value must be greater than the minimum value.

## Displaying volume status for an Aurora PostgreSQL DB cluster

In Amazon Aurora, a DB cluster volume consists of a collection of logical blocks. Each of these represents 10 gigabytes of allocated storage. These blocks are called *protection groups*.

The data in each protection group is replicated across six physical storage devices, called *storage nodes*. These storage nodes are allocated across three Availability Zones (AZs) in the region where the DB cluster resides. In turn, each storage node contains one or more logical blocks of data for the DB cluster volume. For more information about protection groups and storage nodes, see [Introducing the Aurora storage engine](#) on the AWS Database Blog. To learn more about Aurora cluster volumes in general, see [Amazon Aurora storage and reliability \(p. 67\)](#).

Use the `aurora_show_volume_status()` function to return the following server status variables:

- **Disks** — The total number of logical blocks of data for the DB cluster volume.
- **Nodes** — The total number of storage nodes for the DB cluster volume.

You can use the `aurora_show_volume_status()` function to help avoid an error when using the `aurora_inject_disk_failure()` fault injection function. The `aurora_inject_disk_failure()` fault injection function simulates the failure of an entire storage node, or a single logical block of data within a storage node. In the function, you specify the index value of a specific logical block of data or storage node. However, the statement returns an error if you specify an index value greater than the number of logical blocks of data or storage nodes used by the DB cluster volume. For more information about fault injection queries, see [Testing Amazon Aurora PostgreSQL by using fault injection queries \(p. 1147\)](#).

**Note**

The `aurora_show_volume_status()` function is available for Aurora PostgreSQL version 10.11. For more information about Aurora PostgreSQL versions, see [Amazon Aurora PostgreSQL releases and engine versions \(p. 1414\)](#).

### Syntax

```
SELECT * FROM aurora_show_volume_status();
```

### Example

```
customer_database=> SELECT * FROM aurora_show_volume_status();
```

disks	nodes
96	45

## Specifying the RAM disk for the stats\_temp\_directory

You can use the Aurora PostgreSQL parameter, `rds.pg_stat_ramdisk_size`, to specify the system memory allocated to a RAM disk for storing the PostgreSQL `stats_temp_directory`. The RAM disk parameter is available for all Aurora PostgreSQL versions.

Under certain workloads, setting this parameter can improve performance and decrease IO requirements. For more information about the `stats_temp_directory`, see [Run-time Statistics](#) in the PostgreSQL documentation.

To enable a RAM disk for your `stats_temp_directory`, set the `rds.pg_stat_ramdisk_size` parameter to a non-zero value in the DB cluster parameter group used by your DB cluster. This parameter denotes MB, so you must use an integer value. Expressions, formulas, and functions aren't valid for the `rds.pg_stat_ramdisk_size` parameter. Be sure to restart the DB cluster so that the change takes effect. For information about setting parameters, see [Working with parameter groups \(p. 215\)](#). For more information about restarting the DB cluster, see [Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance \(p. 329\)](#).

As an example, the following AWS CLI command sets the RAM disk parameter to 256 MB.

```
aws rds modify-db-cluster-parameter-group \
    --db-cluster-parameter-group-name db-cl-pg-ramdisk-testing \
    --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256,
    ApplyMethod=pending-reboot"
```

After you restart the DB cluster, run the following command to see the status of the `stats_temp_directory`:

```
postgres=> SHOW stats_temp_directory;
```

The command should return the following:

```
stats_temp_directory
-----
/rdsdbramdisk/pg_stat_tmp
(1 row)
```

## Tuning with wait events for Aurora PostgreSQL

Wait events are an important tuning tool for Aurora PostgreSQL. When you can find out why sessions are waiting for resources and what they are doing, you're better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions. Before delving into this section, we strongly recommend that you understand basic Aurora concepts, especially the following topics:

- [Amazon Aurora storage and reliability \(p. 67\)](#)
- [Managing performance and scaling for Aurora DB clusters \(p. 274\)](#)

### Important

The wait events in this section are specific to Aurora PostgreSQL. Use the information in this section to tune Amazon Aurora only, not RDS for PostgreSQL.

Some wait events in this section have no analogs in the open source versions of these database engines. Other wait events have the same names as events in open source engines, but behave differently. For example, Amazon Aurora storage works differently from open source storage, so storage-related wait events indicate different resource conditions.

#### Topics

- [Essential concepts for Aurora PostgreSQL tuning \(p. 1153\)](#)
- [Aurora PostgreSQL wait events \(p. 1156\)](#)

- [Timeout:PgSleep \(p. 1199\)](#)

## Essential concepts for Aurora PostgreSQL tuning

Before you tune your Aurora PostgreSQL database, make sure to learn what wait events are and why they occur. Also review the basic memory and disk architecture of Aurora PostgreSQL. For a helpful architecture diagram, see the [PostgreSQL wikibook](#).

#### Topics

- [Aurora PostgreSQL wait events \(p. 1153\)](#)
- [Aurora PostgreSQL memory \(p. 1154\)](#)
- [Aurora PostgreSQL processes \(p. 1155\)](#)

## Aurora PostgreSQL wait events

A *wait event* indicates a resource for which a session is waiting. For example, the wait event `client:ClientRead` occurs when Aurora PostgreSQL is waiting to receive data from the client. Typical resources that a session waits for include the following:

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

A wait event doesn't by itself show a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

Large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now runs for hours, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

## Aurora PostgreSQL memory

Aurora PostgreSQL memory is divided into shared and local.

### Topics

- [Shared memory in Aurora PostgreSQL \(p. 1154\)](#)
- [Local memory in Aurora PostgreSQL \(p. 1155\)](#)

## Shared memory in Aurora PostgreSQL

Aurora PostgreSQL allocates shared memory when the instance starts. Shared memory is divided into multiple subareas. Following, you can find a description of the most important ones.

### Topics

- [Shared buffers \(p. 1154\)](#)
- [Write ahead log \(WAL\) buffers \(p. 1154\)](#)

### Shared buffers

The *shared buffer pool* is an Aurora PostgreSQL memory area that holds all pages that are or were being used by application connections. A *page* is the memory version of a disk block. The shared buffer pool caches the data blocks read from disk. The pool reduces the need to reread data from disk, making the database operate more efficiently.

Every table and index is stored as an array of pages of a fixed size. Each block contains multiple tuples, which correspond to rows. A tuple can be stored in any page.

The shared buffer pool has finite memory. If a new request requires a page that isn't in memory, and no more memory exists, Aurora PostgreSQL evicts a less frequently used page to accommodate the request. The eviction policy is implemented by a clock sweep algorithm.

The `shared_buffers` parameter determines how much memory the server dedicates to caching data.

### Write ahead log (WAL) buffers

A *write-ahead log (WAL) buffer* holds transaction data that Aurora PostgreSQL later writes to persistent storage. Using the WAL mechanism, Aurora PostgreSQL can do the following:

- Recover data after a failure
- Reduce disk I/O by avoiding frequent writes to disk

When a client changes data, Aurora PostgreSQL writes the changes to the WAL buffer. When the client issues a `COMMIT`, the WAL writer process writes transaction data to the WAL file.

The `wal_level` parameter determines how much information is written to the WAL.

## Local memory in Aurora PostgreSQL

Every backend process allocates local memory for query processing.

### Topics

- [Work memory area \(p. 1155\)](#)
- [Maintenance work memory area \(p. 1155\)](#)
- [Temporary buffer area \(p. 1155\)](#)

### Work memory area

The *work memory area* holds temporary data for queries that performs sorts and hashes. For example, a query with an `ORDER BY` clause performs a sort. Queries use hash tables in hash joins and aggregations.

The `work_mem` parameter specifies the amount of memory to be used by internal sort operations and hash tables before writing to temporary disk files. The default value is 4 MB. Multiple sessions can run simultaneously, and each session can run maintenance operations in parallel. For this reason, the total work memory used can be multiples of the `work_mem` setting.

### Maintenance work memory area

The *maintenance work memory area* caches data for maintenance operations. These operations include vacuuming, creating an index, and adding foreign keys.

The `maintenance_work_mem` parameter specifies the maximum amount of memory to be used by maintenance operations. The default value is 64 MB. A database session can only run one maintenance operation at a time.

### Temporary buffer area

The *temporary buffer area* caches temporary tables for each database session.

Each session allocates temporary buffers as needed up to the limit you specify. When the session ends, the server clears the buffers.

The `temp_buffers` parameter sets the maximum number of temporary buffers used by each session. Before the first use of temporary tables within a session, you can change the `temp_buffers` value.

## Aurora PostgreSQL processes

Aurora PostgreSQL uses multiple processes.

### Topics

- [Postmaster process \(p. 1155\)](#)
- [Backend processes \(p. 1156\)](#)
- [Background processes \(p. 1156\)](#)

### Postmaster process

The *postmaster process* is the first process started when you start Aurora PostgreSQL. The postmaster process has the following primary responsibilities:

- Fork and monitor background processes
- Receive authentication requests from client processes, and authenticate them before allowing the database to service requests

## Backend processes

If the postmaster authenticates a client request, the postmaster forks a new backend process, also called a `postgres` process. One client process connects to exactly one backend process. The client process and the backend process communicate directly without intervention by the postmaster process.

## Background processes

The postmaster process forks several processes that perform different backend tasks. Some of the more important include the following:

- WAL writer

Aurora PostgreSQL writes data in the WAL (write ahead logging) buffer to the log files. The principle of write ahead logging is that the database can't write changes to the data files until after the database writes log records describing those changes to disk. The WAL mechanism reduces disk I/O, and allows Aurora PostgreSQL to use the logs to recover the database after a failure.

- Background writer

This process periodically writes dirty (modified) pages from the memory buffers to the data files. A page becomes dirty when a backend process modifies it in memory.

- Autovacuum daemon

The daemon consists of the following:

- The autovacuum launcher
- The autovacuum worker processes

When autovacuum is turned on, it checks for tables that have had a large number of inserted, updated, or deleted tuples. The daemon has the following responsibilities:

- Recover or reuse disk space occupied by updated or deleted rows
- Update statistics used by the planner
- Protect against loss of old data because of transaction ID wraparound

The autovacuum feature automates the execution of `VACUUM` and `ANALYZE` commands. `VACUUM` has the following variants: standard and full. Standard vacuum runs in parallel with other database operations. `VACUUM FULL` requires an exclusive lock on the table it is working on. Thus, it can't run in parallel with operations that access the same table. `VACUUM` creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions.

## Aurora PostgreSQL wait events

The following table lists the wait events for Aurora PostgreSQL that most commonly indicate performance problems, and summarizes the most common causes and corrective actions. The following wait events are a subset of the list in [Amazon Aurora PostgreSQL wait events \(p. 1395\)](#).

Wait event	Definition
<a href="#">Client:ClientRead (p. 1158)</a>	This event occurs when Aurora PostgreSQL is waiting to receive data from the client.

Wait event	Definition
<a href="#">Client:ClientWrite (p. 1160)</a>	This event occurs when Aurora PostgreSQL is waiting to write data to the client.
<a href="#">CPU (p. 1161)</a>	This event occurs when a thread is active in CPU or is waiting for CPU.
<a href="#">IO:BufFileRead and IO:BufFileWrite (p. 1166)</a>	These events occur when Aurora PostgreSQL creates temporary files.
<a href="#">IO:DataFileRead (p. 1171)</a>	This event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.
<a href="#">IO:XactSync (p. 1177)</a>	This event occurs when the database is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction.
<a href="#">ipc:damrecordtxack (p. 1179)</a>	This event occurs when Aurora PostgreSQL in a session using database activity streams generates an activity stream event, then waits for that event to become durable.
<a href="#">Lock:advisory (p. 1180)</a>	This event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.
<a href="#">Lock:extend (p. 1182)</a>	This event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.
<a href="#">Lock:Relation (p. 1184)</a>	This event occurs when a query is waiting to acquire a lock on a table or view that's currently locked by another transaction.
<a href="#">Lock:transactionid (p. 1187)</a>	This event occurs when a transaction is waiting for a row-level lock.
<a href="#">Lock:tuple (p. 1189)</a>	This event occurs when a backend process is waiting to acquire a lock on a tuple.
<a href="#">lwlock:buffer_content (BufferContent) (p. 1192)</a>	This event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing.
<a href="#">LWLock:buffer_mapping (p. 1193)</a>	This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.
<a href="#">LWLock:BufferIO (p. 1195)</a>	This event occurs when Aurora PostgreSQL or RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page.
<a href="#">LWLock:lock_manager (p. 1196)</a>	This event occurs when the Aurora PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.
<a href="#">Timeout:PgSleep (p. 1199)</a>	This event occurs when a server process has called the pg_sleep function and is waiting for the sleep timeout to expire.

## Client:ClientRead

The `Client:ClientRead` event occurs when Aurora PostgreSQL is waiting to receive data from the client.

### Topics

- [Supported engine versions \(p. 1158\)](#)
- [Context \(p. 1158\)](#)
- [Likely causes of increased waits \(p. 1158\)](#)
- [Actions \(p. 1159\)](#)

## Supported engine versions

This wait event information is supported for Aurora PostgreSQL version 10 and higher.

## Context

An Aurora PostgreSQL DB cluster is waiting to receive data from the client. The Aurora PostgreSQL DB cluster must receive the data from the client before it can send more data to the client. The time that the cluster waits before receiving data from the client is a `Client:ClientRead` event.

## Likely causes of increased waits

Common causes for the `Client:ClientRead` event to appear in top waits include the following:

### Increased network latency

There might be increased network latency between the Aurora PostgreSQL DB cluster and client. Higher network latency increases the time required for DB cluster to receive data from the client.

### Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client can delay transmission of data from the client to the Aurora PostgreSQL DB cluster.

### Excessive network round trips

A large number of network round trips between the Aurora PostgreSQL DB cluster and the client can delay transmission of data from the client to the Aurora PostgreSQL DB cluster.

### Large copy operation

During a copy operation, the data is transferred from the client's file system to the Aurora PostgreSQL DB cluster. Sending a large amount of data to the DB cluster can delay transmission of data from the client to the DB cluster.

### Idle client connection

When a client connects to the Aurora PostgreSQL DB cluster in an `idle in transaction` state, the DB cluster might wait for the client to send more data or issue a command. A connection in this state can lead to an increase in `Client:ClientRead` events.

### PgBouncer used for connection pooling

PgBouncer has a low-level network configuration setting called `pkt_buf`, which is set to 4,096 by default. If the workload is sending query packets larger than 4,096 bytes through PgBouncer, we recommend increasing the `pkt_buf` setting to 8,192. If the new setting doesn't decrease the number of `Client:ClientRead` events, we recommend increasing the `pkt_buf` setting to larger

values, such as 16,384 or 32,768. If the query text is large, the larger setting can be particularly helpful.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Place the clients in the same Availability Zone and VPC subnet as the cluster \(p. 1159\)](#)
- [Scale your client \(p. 1159\)](#)
- [Use current generation instances \(p. 1159\)](#)
- [Increase network bandwidth \(p. 1159\)](#)
- [Monitor maximums for network performance \(p. 1159\)](#)
- [Monitor for transactions in the "idle in transaction" state \(p. 1160\)](#)

### Place the clients in the same Availability Zone and VPC subnet as the cluster

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the Aurora PostgreSQL DB cluster. Make sure that the clients are as geographically close to the DB cluster as possible.

### Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

### Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see [Jumbo frames \(9001 MTU\)](#) in the *Amazon EC2 User Guide for Linux Instances*.

For information about DB instance classes, see [Aurora DB instance classes \(p. 56\)](#). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place db. before the Amazon EC2 instance type name. For example, the r5.8xlarge Amazon EC2 instance is equivalent to the db.r5.8xlarge DB instance class.

### Increase network bandwidth

Use NetworkReceiveThroughput and NetworkTransmitThroughput Amazon CloudWatch metrics to monitor incoming and outgoing network traffic on the DB cluster. These metrics can help you to determine if network bandwidth is sufficient for your workload.

If your network bandwidth isn't enough, increase it. If the AWS client or your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see [Amazon CloudWatch metrics for Amazon Aurora \(p. 525\)](#).

### Monitor maximums for network performance

If you are using Amazon EC2 clients, Amazon EC2 provides maximums for network performance metrics, including aggregate inbound and outbound network bandwidth. It also provides connection tracking to ensure that packets are returned as expected and link-local services access for services such as the

Domain Name System (DNS). To monitor these maximums, use a current enhanced networking driver and monitor network performance for your client.

For more information, see [Monitor network performance for your Amazon EC2 instance](#) in the *Amazon EC2 User Guide for Linux Instances* and [Monitor network performance for your Amazon EC2 instance](#) in the *Amazon EC2 User Guide for Windows Instances*.

## Monitor for transactions in the "idle in transaction" state

Check whether you have an increasing number of `idle in transaction` connections. To do this, monitor the `state` column in the `pg_stat_activity` table. You might be able to identify the connection source by running a query similar to the following.

```
select client_addr, state, count(1) from pg_stat_activity
where state like 'idle in transaction%'
group by 1,2
order by 3 desc
```

## Client:ClientWrite

The `Client:ClientWrite` event occurs when Aurora PostgreSQL is waiting to write data to the client.

### Topics

- [Supported engine versions \(p. 1160\)](#)
- [Context \(p. 1160\)](#)
- [Likely causes of increased waits \(p. 1160\)](#)
- [Actions \(p. 1161\)](#)

## Supported engine versions

This wait event information is supported for Aurora PostgreSQL version 10 and higher.

## Context

A client process must read all of the data received from an Aurora PostgreSQL DB cluster before the cluster can send more data. The time that the cluster waits before sending more data to the client is a `Client:ClientWrite` event.

Reduced network throughput between the Aurora PostgreSQL DB cluster and the client can cause this event. CPU pressure and network saturation on the client can also cause this event. *CPU pressure* is when the CPU is fully utilized and there are tasks waiting for CPU time. *Network saturation* is when the network between the database and client is carrying more data than it can handle.

## Likely causes of increased waits

Common causes for the `Client:ClientWrite` event to appear in top waits include the following:

### Increased network latency

There might be increased network latency between the Aurora PostgreSQL DB cluster and client. Higher network latency increases the time required for the client to receive the data.

### Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client delays the reception of data from the Aurora PostgreSQL DB cluster.

## Large volume of data sent to the client

The Aurora PostgreSQL DB cluster might be sending a large amount of data to the client. A client might not be able to receive the data as fast as the cluster is sending it. Activities such as a copy of a large table can result in an increase in `Client:ClientWrite` events.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Place the clients in the same Availability Zone and VPC subnet as the cluster \(p. 1161\)](#)
- [Use current generation instances \(p. 1161\)](#)
- [Reduce the amount of data sent to the client \(p. 1161\)](#)
- [Scale your client \(p. 1161\)](#)

### Place the clients in the same Availability Zone and VPC subnet as the cluster

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the Aurora PostgreSQL DB cluster.

### Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see [Jumbo frames \(9001 MTU\)](#) in the *Amazon EC2 User Guide for Linux Instances*.

For information about DB instance classes, see [Aurora DB instance classes \(p. 56\)](#). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

### Reduce the amount of data sent to the client

When possible, adjust your application to reduce the amount of data that the Aurora PostgreSQL DB cluster sends to the client. Making such adjustments relieves CPU and network contention on the client.

### Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

## CPU

This event occurs when a thread is active in CPU or is waiting for CPU.

### Topics

- [Supported engine versions \(p. 1162\)](#)
- [Context \(p. 1162\)](#)
- [Likely causes of increased waits \(p. 1163\)](#)
- [Actions \(p. 1164\)](#)

## Supported engine versions

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

### Context

The *central processing unit (CPU)* is the component of a computer that runs instructions. For example, CPU instructions perform arithmetic operations and exchange data in memory. If a query increases the number of instructions that it performs through the database engine, the time spent running the query increases. *CPU scheduling* is giving CPU time to a process. Scheduling is orchestrated by the kernel of the operating system.

#### Topics

- [How to tell when this wait occurs \(p. 1162\)](#)
- [DBLoadCPU metric \(p. 1162\)](#)
- [os.cpuUtilization metrics \(p. 1162\)](#)
- [Likely cause of CPU scheduling \(p. 1163\)](#)

### How to tell when this wait occurs

This CPU wait event indicates that a backend process is active in CPU or is waiting for CPU. You know that it's occurring when a query shows the following information:

- The `pg_stat_activity.state` column has the value `active`.
- The `wait_event_type` and `wait_event` columns in `pg_stat_activity` are both `null`.

To see the backend processes that are using or waiting on CPU, run the following query.

```
SELECT *
FROM   pg_stat_activity
WHERE  state = 'active'
AND    wait_event_type IS NULL
AND    wait_event IS NULL;
```

### DBLoadCPU metric

The Performance Insights metric for CPU is DBLoadCPU. The value for DBLoadCPU can differ from the value for the Amazon CloudWatch metric CPUUtilization. The latter metric is collected from the HyperVisor for a database instance.

### os.cpuUtilization metrics

Performance Insights operating-system metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`
- `os.cpuUtilization.wait.avg`
- `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

## Likely cause of CPU scheduling

From an operating system perspective, the CPU is active when it isn't running the idle thread. The CPU is active while it performs a computation, but it's also active when it waits on memory I/O. This type of I/O dominates a typical database workload.

Processes are likely to wait to get scheduled on a CPU when the following conditions are met:

- The CloudWatch CPUUtilization metric is near 100 percent.
- The average load is greater than the number of vCPUs, indicating a heavy load. You can find the loadAverageMinute metric in the OS metrics section in Performance Insights.

## Likely causes of increased waits

When the CPU wait event occurs more than normal, possibly indicating a performance problem, typical causes include the following.

### Topics

- [Likely causes of sudden spikes \(p. 1163\)](#)
- [Likely causes of long-term high frequency \(p. 1163\)](#)
- [Corner cases \(p. 1163\)](#)

### Likely causes of sudden spikes

The most likely causes of sudden spikes are as follows:

- Your application has opened too many simultaneous connections to the database. This scenario is known as a "connection storm."
- Your application workload changed in any of the following ways:
  - New queries
  - An increase in the size of your dataset
  - Index maintenance or creation
  - New functions
  - New operators
  - An increase in parallel query execution
- Your query execution plans have changed. In some cases, a change can cause an increase in buffers. For example, the query is now using a sequential scan when it previously used an index. In this case, the queries need more CPU to accomplish the same goal.

### Likely causes of long-term high frequency

The most likely causes of events that recur over a long period:

- Too many backend processes are running concurrently on CPU. These processes can be parallel workers.
- Queries are performing suboptimally because they need a large number of buffers.

### Corner cases

If none of the likely causes turn out to be actual causes, the following situations might be occurring:

- The CPU is swapping processes in and out.
- CPU context switching has increased.
- Aurora PostgreSQL code is missing wait events.

## Actions

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

### Topics

- [Investigate whether the database is causing the CPU increase \(p. 1164\)](#)
- [Determine whether the number of connections increased \(p. 1164\)](#)
- [Respond to workload changes \(p. 1165\)](#)

### Investigate whether the database is causing the CPU increase

Examine the `os.cpuUtilization.nice.avg` metric in Performance Insights. If this value is far less than the CPU usage, nondatabase processes are the main contributor to CPU.

### Determine whether the number of connections increased

Examine the `DatabaseConnections` metric in Amazon CloudWatch. Your action depends on whether the number increased or decreased during the period of increased CPU wait events.

#### The connections increased

If the number of connections went up, compare the number of backend processes consuming CPU to the number of vCPUs. The following scenarios are possible:

- The number of backend processes consuming CPU is less than the number of vCPUs.

In this case, the number of connections isn't an issue. However, you might still try to reduce CPU utilization.

- The number of backend processes consuming CPU is greater than the number of vCPUs.

In this case, consider the following options:

- Decrease the number of backend processes connected to your database. For example, implement a connection pooling solution such as RDS Proxy. To learn more, see [Using Amazon RDS Proxy \(p. 1430\)](#).
- Upgrade your instance size to get a higher number of vCPUs.
- Redirect some read-only workloads to reader nodes, if applicable.

#### The connections didn't increase

Examine the `blk_hit` metrics in Performance Insights. Look for a correlation between an increase in `blk_hit` and CPU usage. The following scenarios are possible:

- CPU usage and `blk_hit` are correlated.

In this case, find the top SQL statements that are linked to the CPU usage, and look for plan changes. You can use either of the following techniques:

- Explain the plans manually and compare them to the expected execution plan.

- Look for an increase in block hits per second and local block hits per second. In the **Top SQL** section of Performance Insights dashboard, choose **Preferences**.
- CPU usage and `blk_hit` aren't correlated.

In this case, determine whether any of the following occurs:

- The application is rapidly connecting to and disconnecting from the database.

Diagnose this behavior by turning on `log_connections` and `log_disconnections`, then analyzing the PostgreSQL logs. Consider using the `pgbadger` log analyzer. For more information, see <https://github.com/darold/pgbadger>.

- The OS is overloaded.

In this case, Performance Insights shows that backend processes are consuming CPU for a longer time than usual. Look for evidence in the Performance Insights `os.cpuUtilization` metrics or the CloudWatch `CPUUtilization` metric. If the operating system is overloaded, look at Enhanced Monitoring metrics to diagnose further. Specifically, look at the process list and the percentage of CPU consumed by each process.

- Top SQL statements are consuming too much CPU.

Examine statements that are linked to the CPU usage to see whether they can use less CPU. Run an `EXPLAIN` command, and focus on the plan nodes that have the most impact. Consider using a PostgreSQL execution plan visualizer. To try out this tool, see <http://explain.dalibo.com/>.

## Respond to workload changes

If your workload has changed, look for the following types of changes:

### New queries

Check whether the new queries are expected. If so, ensure that their execution plans and the number of executions per second are expected.

### An increase in the size of the data set

Determine whether partitioning, if it's not already implemented, might help. This strategy might reduce the number of pages that a query needs to retrieve.

### Index maintenance or creation

Check whether the schedule for the maintenance is expected. A best practice is to schedule maintenance activities outside of peak activities.

### New functions

Check whether these functions perform as expected during testing. Specifically, check whether the number of executions per second is expected.

### New operators

Check whether they perform as expected during the testing.

### An increase in running parallel queries

Determine whether any of the following situations has occurred:

- The relations or indexes involved have suddenly grown in size so that they differ significantly from `min_parallel_table_scan_size` or `min_parallel_index_scan_size`.
- Recent changes have been made to `parallel_setup_cost` or `parallel_tuple_cost`.
- Recent changes have been made to `max_parallel_workers` or `max_parallel_workers_per_gather`.

## IO:BuffFileRead and IO:BuffFileWrite

The `IO:BuffFileRead` and `IO:BuffFileWrite` events occur when Aurora PostgreSQL creates temporary files. When operations require more memory than the working memory parameters currently define, they write temporary data to persistent storage. This operation is sometimes called "spilling to disk."

### Topics

- [Supported engine versions \(p. 1166\)](#)
- [Context \(p. 1166\)](#)
- [Likely causes of increased waits \(p. 1166\)](#)
- [Actions \(p. 1167\)](#)

### Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

### Context

`IO:BuffFileRead` and `IO:BuffFileWrite` relate to the work memory area and maintenance work memory area. For more information about these local memory areas, see [Work memory area \(p. 1155\)](#) and [Maintenance work memory area \(p. 1155\)](#).

The default value for `work_mem` is 4 MB. If one session performs operations in parallel, each worker handling the parallelism uses 4 MB of memory. For this reason, set `work_mem` carefully. If you increase the value too much, a database running many sessions might consume too much memory. If you set the value too low, Aurora PostgreSQL creates temporary files in local storage. The disk I/O for these temporary files can reduce performance.

If you observe the following sequence of events, your database might be generating temporary files:

1. Sudden and sharp decreases in availability
2. Fast recovery for the free space

You might also see a "chainsaw" pattern. This pattern can indicate that your database is creating small files constantly.

### Likely causes of increased waits

In general, these wait events are caused by operations that consume more memory than the `work_mem` or `maintenance_work_mem` parameters allocate. To compensate, the operations write to temporary files. Common causes for the `IO:BuffFileRead` and `IO:BuffFileWrite` events include the following:

#### Queries that need more memory than exists in the work memory area

Queries with the following characteristics use the work memory area:

- Hash joins
- `ORDER BY` clause
- `GROUP BY` clause
- `DISTINCT`
- Window functions
- `CREATE TABLE AS SELECT`
- Materialized view refresh

## Statements that need more memory than exists in the maintenance work memory area

The following statements use the maintenance work memory area:

- CREATE INDEX
- CLUSTER

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Identify the problem \(p. 1167\)](#)
- [Examine your join queries \(p. 1167\)](#)
- [Examine your ORDER BY and GROUP BY queries \(p. 1168\)](#)
- [Avoid using the DISTINCT operation \(p. 1169\)](#)
- [Consider using window functions instead of GROUP BY functions \(p. 1169\)](#)
- [Investigate materialized views and CTAS statements \(p. 1170\)](#)
- [Use pg\\_repack when you create indexes \(p. 1170\)](#)
- [Increase maintenance\\_work\\_mem when you cluster tables \(p. 1170\)](#)
- [Tune memory to prevent IO:BufFileRead and IO:BufFileWrite \(p. 1170\)](#)

### Identify the problem

Assume a situation in which Performance Insights isn't turned on and you suspect that IO:BufFileRead and IO:BufFileWrite are occurring more frequently than is normal. Do the following:

1. Examine the `FreeLocalStorage` metric in Amazon CloudWatch.
2. Look for a chainsaw pattern, which is a series of jagged spikes.

A chainsaw pattern indicates a quick consumption and release of storage, often associated with temporary files. If you notice this pattern, turn on Performance Insights. When using Performance Insights, you can identify when the wait events occur and which queries are associated with them. Your solution depends on the specific query causing the events.

Or set the parameter `log_temp_files`. This parameter logs all queries generating more than threshold KB of temporary files. If the value is 0, Aurora PostgreSQL logs all temporary files. If the value is 1024, Aurora PostgreSQL logs all queries that produce temporary files larger than 1 MB. For more information about `log_temp_files`, see [Error Reporting and Logging](#) in the PostgreSQL documentation.

### Examine your join queries

Your application probably uses joins. For example, the following query joins four tables.

```
SELECT *
  FROM order
INNER JOIN order_item
    ON (order.id = order_item.order_id)
INNER JOIN customer
    ON (customer.id = order.customer_id)
INNER JOIN customer_address
    ON (customer_address.customer_id = customer.id AND
```

```
order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```

A possible cause of spikes in temporary file usage is a problem in the query itself. For example, a broken clause might not filter the joins properly. Consider the second inner join in the following example.

```
SELECT *
    FROM order
  INNER JOIN order_item
    ON (order.id = order_item.order_id)
  INNER JOIN customer
    ON (customer.id = customer.id)
  INNER JOIN customer_address
    ON (customer_address.customer_id = customer.id AND
        order.customer_address_id = customer_address.id)
 WHERE customer.id = 1234567890;
```

The preceding query mistakenly joins `customer.id` to `customer.id`, generating a Cartesian product between every customer and every order. This type of accidental join generates large temporary files. Depending on the size of the tables, a Cartesian query can even fill up storage. Your application might have Cartesian joins when the following conditions are met:

- You see large, sharp decreases in storage availability, followed by fast recovery.
- No indexes are being created.
- No `CREATE TABLE FROM SELECT` statements are being issued.
- No materialized views are being refreshed.

To see whether the tables are being joined using the proper keys, inspect your query and object-relational mapping directives. Bear in mind that certain queries of your application are not called all the time, and some queries are dynamically generated.

## Examine your ORDER BY and GROUP BY queries

In some cases, an `ORDER BY` clause can result in excessive temporary files. Consider the following guidelines:

- Only include columns in an `ORDER BY` clause when they need to be ordered. This guideline is especially important for queries that return thousands of rows and specify many columns in the `ORDER BY` clause.
- Considering creating indexes to accelerate `ORDER BY` clauses when they match columns that have the same ascending or descending order. Partial indexes are preferable because they are smaller. Smaller indexes are read and traversed more quickly.
- If you create indexes for columns that can accept null values, consider whether you want the null values stored at the end or at the beginning of the indexes.

- If possible, reduce the number of rows that need to be ordered by filtering the result set. If you use `WITH` clause statements or subqueries, remember that an inner query generates a result set and passes it to the outside query. The more rows that a query can filter out, the less ordering the query needs to do.
- If you don't need to obtain the full result set, use the `LIMIT` clause. For example, if you only want the top five rows, a query using the `LIMIT` clause doesn't keep generating results. In this way, the query requires less memory and temporary files.

A query that uses a `GROUP BY` clause can also require temporary files. `GROUP BY` queries summarize values by using functions such as the following:

- COUNT
- AVG
- MIN
- MAX
- SUM
- STDDEV

To tune `GROUP BY` queries, follow the recommendations for `ORDER BY` queries.

## Avoid using the `DISTINCT` operation

If possible, avoid using the `DISTINCT` operation to remove duplicated rows. The more unnecessary and duplicated rows that your query returns, the more expensive the `DISTINCT` operation becomes. If possible, add filters in the `WHERE` clause even if you use the same filters for different tables. Filtering the query and joining correctly improves your performance and reduces resource use. It also prevents incorrect reports and results.

If you need to use `DISTINCT` for multiple rows of a same table, consider creating a composite index. Grouping multiple columns in an index can improve the time to evaluate distinct rows. Also, if you use Amazon Aurora PostgreSQL version 10 or higher, you can correlate statistics among multiple columns by using the `CREATE STATISTICS` command.

## Consider using window functions instead of `GROUP BY` functions

Using `GROUP BY`, you change the result set, and then retrieve the aggregated result. Using window functions, you aggregate data without changing the result set. A window function uses the `OVER` clause to perform calculations across the sets defined by the query, correlating one row with another. You can use all the `GROUP BY` functions in window functions, but also use functions such as the following:

- RANK
- ARRAY\_AGG
- ROW\_NUMBER
- LAG
- LEAD

To minimize the number of temporary files generated by a window function, remove duplications for the same result set when you need two distinct aggregations. Consider the following query.

```
SELECT sum(salary) OVER (PARTITION BY dept ORDER BY salary DESC) as sum_salary
      , avg(salary) OVER (PARTITION BY dept ORDER BY salary ASC) as avg_salary
   FROM empsalary;
```

You can rewrite the query with the `WINDOW` clause as follows.

```
SELECT sum(salary) OVER w as sum_salary
      , avg(salary) OVER w as avg_salary
   FROM empsalary
 WINDOW w AS (PARTITION BY dept ORDER BY salary DESC);
```

By default, the Aurora PostgreSQL execution planner consolidates similar nodes so that it doesn't duplicate operations. However, by using an explicit declaration for the window block, you can maintain the query more easily. You might also improve performance by preventing duplication.

## Investigate materialized views and CTAS statements

When a materialized view refreshes, it runs a query. This query can contain an operation such as GROUP BY, ORDER BY, or DISTINCT. During a refresh, you might observe large numbers of temporary files and the wait events IO:BufFileWrite and IO:BufFileRead. Similarly, when you create a table based on a SELECT statement, the CREATE TABLE statement runs a query. To reduce the temporary files needed, optimize the query.

## Use pg\_repack when you create indexes

When you create an index, the engine orders the result set. As tables grow in size, and as values in the indexed column become more diverse, the temporary files require more space. In most cases, you can't prevent the creation of temporary files for large tables without modifying the maintenance work memory area. For more information, see [Maintenance work memory area \(p. 1155\)](#).

A possible workaround when recreating a large index is to use the pg\_repack tool. For more information, see [Reorganize tables in PostgreSQL databases with minimal locks](#) in the pg\_repack documentation.

## Increase maintenance\_work\_mem when you cluster tables

The CLUSTER command clusters the table specified by *table\_name* based on an existing index specified by *index\_name*. Aurora PostgreSQL physically recreates the table to match the order of a given index.

When magnetic storage was prevalent, clustering was common because storage throughput was limited. Now that SSD-based storage is common, clustering is less popular. However, if you cluster tables, you can still increase performance slightly depending on the table size, index, query, and so on.

If you run the CLUSTER command and observe the wait events IO:BufFileWrite and IO:BufFileRead, tune maintenance\_work\_mem. Increase the memory size to a fairly large amount. A high value means that the engine can use more memory for the clustering operation.

## Tune memory to prevent IO:BufFileRead and IO:BufFileWrite

In some situation, you need to tune memory. Your goal is to balance the following requirements:

- The `work_mem` value (see [Work memory area \(p. 1155\)](#))
- The memory remaining after discounting the `shared_buffers` value (see [Buffer pool \(p. 748\)](#))
- The maximum connections opened and in use, which is limited by `max_connections`

## Increase the size of the work memory area

In some situations, your only option is to increase the memory used by your session. If your queries are correctly written and are using the correct keys for joins, consider increasing the `work_mem` value. For more information, see [Work memory area \(p. 1155\)](#).

To find out how many temporary files a query generates, set `log_temp_files` to 0. If you increase the `work_mem` value to the maximum value identified in the logs, you prevent the query from generating temporary files. However, `work_mem` sets the maximum per plan node for each connection or parallel worker. If the database has 5,000 connections, and if each one uses 256 MiB memory, the engine needs 1.2 TiB of RAM. Thus, your instance might run out of memory.

## Reserve sufficient memory for the shared buffer pool

Your database uses memory areas such as the shared buffer pool, not just the work memory area. Consider the requirements of these additional memory areas before you increase `work_mem`. For more information about the buffer pool, see [Buffer pool \(p. 748\)](#).

For example, assume that your Aurora PostgreSQL instance class is db.r5.2xlarge. This class has 64 GiB of memory. By default, 75 percent of the memory is reserved for the shared buffer pool. After you subtract

the amount allocated to the shared memory area, 16,384 MB remains. Don't allocate the remaining memory exclusively to the work memory area because the operating system and the engine also require memory.

The memory that you can allocate to `work_mem` depends on the instance class. If you use a larger instance class, more memory is available. However, in the preceding example, you can't use more than 16 GiB. Otherwise, your instance becomes unavailable when it runs out of memory. To recover the instance from the unavailable state, the Aurora PostgreSQL automation services automatically restart.

### Manage the number of connections

Suppose that your database instance has 5,000 simultaneous connections. Each connection uses at least 4 MiB of `work_mem`. The high memory consumption of the connections is likely to degrade performance. In response, you have the following options:

- Upgrade to a larger instance class.
- Decrease the number of simultaneous database connections by using a connection proxy or pooler.

For proxies, consider Amazon RDS Proxy, pgBouncer, or a connection pooler based on your application. This solution alleviates the CPU load. It also reduces the risk when all connections require the work memory area. When fewer database connections exist, you can increase the value of `work_mem`. In this way, you reduce the occurrence of the `IO:BuffFileRead` and `IO:BuffFileWrite` wait events. Also, the queries waiting for the work memory area speed up significantly.

## IO:DataFileRead

The `IO:DataFileRead` event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.

### Topics

- [Supported engine versions \(p. 1171\)](#)
- [Context \(p. 1171\)](#)
- [Likely causes of increased waits \(p. 1171\)](#)
- [Actions \(p. 1172\)](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

All queries and data manipulation (DML) operations access pages in the buffer pool. Statements that can induce reads include `SELECT`, `UPDATE`, and `DELETE`. For example, an `UPDATE` can read pages from tables or indexes. If the page being requested or updated isn't in the shared buffer pool, this read can lead to the `IO:DataFileRead` event.

Because the shared buffer pool is finite, it can fill up. In this case, requests for pages that aren't in memory force the database to read blocks from disk. If the `IO:DataFileRead` event occurs frequently, your shared buffer pool might be too small to accommodate your workload. This problem is acute for `SELECT` queries that read a large number of rows that don't fit in the buffer pool. For more information about the buffer pool, see [Buffer pool \(p. 748\)](#).

## Likely causes of increased waits

Common causes for the `IO:DataFileRead` event include the following:

## Connection spikes

You might find multiple connections generating the same number of IO:DataFileRead wait events. In this case, a spike (sudden and large increase) in IO:DataFileRead events can occur.

## SELECT and DML statements performing sequential scans

Your application might be performing a new operation. Or an existing operation might change because of a new execution plan. In such cases, look for tables (particularly large tables) that have a greater seq\_scan value. Find them by querying pg\_stat\_user\_tables. To track queries that are generating more read operations, use the extension pg\_stat\_statements.

## CTAS and CREATE INDEX for large data sets

A CTAS is a CREATE TABLE AS SELECT statement. If you run a CTAS using a large data set as a source, or create an index on a large table, the IO:DataFileRead event can occur. When you create an index, the database might need to read the entire object using a sequential scan. A CTAS generates IO:DataFile reads when pages aren't in memory.

## Multiple vacuum workers running at the same time

Vacuum workers can be triggered manually or automatically. We recommend adopting an aggressive vacuum strategy. However, when a table has many updated or deleted rows, the IO:DataFileRead waits increase. After space is reclaimed, the vacuum time spent on IO:DataFileRead decreases.

## Ingesting large amounts of data

When your application ingests large amounts of data, ANALYZE operations might occur more often. The ANALYZE process can be triggered by an autovacuum launcher or invoked manually.

The ANALYZE operation reads a subset of the table. The number of pages that must be scanned is calculated by multiplying 30 by the default\_statistics\_target value. For more information, see the [PostgreSQL documentation](#). The default\_statistics\_target parameter accepts values between 1 and 10,000, where the default is 100.

## Resource starvation

If instance network bandwidth or CPU are consumed, the IO:DataFileRead event might occur more frequently.

# Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Check predicate filters for queries that generate waits \(p. 1172\)](#)
- [Minimize the effect of maintenance operations \(p. 1173\)](#)
- [Respond to high numbers of connections \(p. 1177\)](#)

## Check predicate filters for queries that generate waits

Assume that you identify specific queries that are generating IO:DataFileRead wait events. You might identify them using the following techniques:

- Performance Insights
- Catalog views such as the one provided by the extension pg\_stat\_statements
- The catalog view pg\_stat\_all\_tables, if it periodically shows an increased number of physical reads

- The `pg_statio_all_tables` view, if it shows that `_read` counters are increasing

We recommend that you determine which filters are used in the predicate (`WHERE` clause) of these queries. Follow these guidelines:

- Run the `EXPLAIN` command. In the output, identify which types of scans are used. A sequential scan doesn't necessarily indicate a problem. Queries that use sequential scans naturally produce more `IO:DataFileRead` events when compared to queries that use filters.

Find out whether the column listed in the `WHERE` clause is indexed. If not, consider creating an index for this column. This approach avoids the sequential scans and reduces the `IO:DataFileRead` events. If a query has restrictive filters and still produces sequential scans, evaluate whether the proper indexes are being used.

- Find out whether the query is accessing a very large table. In some cases, partitioning a table can improve performance, allowing the query to only read necessary partitions.
- Examine the cardinality (total number of rows) from your join operations. Note how restrictive the values are that you're passing in the filters for your `WHERE` clause. If possible, tune your query to reduce the number of rows that are passed in each step of the plan.

## Minimize the effect of maintenance operations

Maintenance operations such as `VACUUM` and `ANALYZE` are important. We recommend that you don't turn them off because you find `IO:DataFileRead` wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours. This technique prevents the database from reaching the threshold for automatic operations.
- For very large tables, consider partitioning the table. This technique reduces the overhead of maintenance operations. The database only accesses the partitions that require maintenance.
- When you ingest large amounts of data, consider disabling the autoanalyze feature.

The autovacuum feature is automatically triggered for a table when the following formula is true.

```
pg_stat_user_tables.n_dead_tup > (pg_class.reltuples * autovacuum_vacuum_scale_factor) +  
autovacuum_vacuum_threshold
```

The view `pg_stat_user_tables` and catalog `pg_class` have multiple rows. One row can correspond to one row in your table. This formula assumes that the `reltuples` are for a specific table. The parameters `autovacuum_vacuum_scale_factor` (0.20 by default) and `autovacuum_vacuum_threshold` (50 tuples by default) are usually set globally for the whole instance. However, you can set different values for a specific table.

### Topics

- [Find tables consuming unnecessary space \(p. 1173\)](#)
- [Find indexes consuming unnecessary space \(p. 1175\)](#)
- [Find tables that are eligible to be autovacuumed \(p. 1176\)](#)

## Find tables consuming unnecessary space

To find tables consuming unnecessary space, run the following query.

```
/* WARNING: Run with a nonsuperuser role, the query inspects only tables  
* that you have the permission to read.
```

```

* This query is compatible with PostgreSQL 9.0 and later.
*/

SELECT current_database(), schemaname, tblname, bs*tblpages AS real_size,
       (tblpages-est_tblpages)*bs AS extra_size,
       CASE WHEN tblpages - est_tblpages > 0
             THEN 100 * (tblpages - est_tblpages)/tblpages::float
             ELSE 0
       END AS extra_ratio, fillfactor, (tblpages-est_tblpages_ff)*bs AS bloat_size,
       CASE WHEN tblpages - est_tblpages_ff > 0
             THEN 100 * (tblpages - est_tblpages_ff)/tblpages::float
             ELSE 0
       END AS bloat_ratio, is_na
       -- , (pst).free_percent + (pst).dead_tuple_percent AS real_frag
FROM (
  SELECT
    ceil( reltuples / ( (bs-page_hdr)/tpl_size ) ) + ceil( toasttuples / 4 )
      AS est_tblpages,
    ceil( reltuples / ( (bs-page_hdr)*fillfactor/(tpl_size*100) ) ) + ceil( toasttuples / 4 )
      AS est_tblpages_ff,

ORDER BY age(relfrozenxid) DES;

```

## Respond to high numbers of connections

When you monitor Amazon CloudWatch, you might find that the `DatabaseConnections` metric spikes. This increase indicates an increased number of connections to your database. We recommend the following approach:

- Limit the number of connections that the application can open with each instance. If your application has an embedded connection pool feature, set a reasonable number of connections. Base the number on what the vCPUs in your instance can parallelize effectively.

If your application doesn't use a connection pool feature, consider using Amazon RDS Proxy or an alternative. This approach lets your application open multiple connections with the load balancer. The balancer can then open a restricted number of connections with the database. As fewer connections are running in parallel, your DB instance performs less context switching in the kernel. Queries should progress faster, leading to fewer wait events. For more information, see [Using Amazon RDS Proxy \(p. 1430\)](#).

- Whenever possible, take advantage of reader nodes for Aurora PostgreSQL and read replicas for RDS for PostgreSQL. When your application runs a read-only operation, send these requests to the reader-only endpoint. This technique spreads application requests across all reader nodes, reducing the I/O pressure on the writer node.
- Consider scaling up your DB instance. A higher-capacity instance class gives more memory, which gives Aurora PostgreSQL a larger shared buffer pool to hold pages. The larger size also gives the DB instance more vCPUs to handle connections. More vCPUs are particularly helpful when the operations that are generating `IO:DataFileRead` wait events are writes.

## IO:XactSync

The `IO:XactSync` event occurs when the database is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction. A prepared transaction is part of PostgreSQL's support for a two-phase commit.

### Topics

- [Supported engine versions \(p. 1178\)](#)
- [Context \(p. 1178\)](#)
- [Likely causes of increased waits \(p. 1178\)](#)
- [Actions \(p. 1178\)](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

The event `IO:XactSync` indicates that the instance is spending time waiting for the Aurora storage subsystem to confirm that transaction data was processed.

## Likely causes of increased waits

When the `IO:XactSync` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

### Network saturation

Traffic between clients and the DB instance or traffic to the storage subsystem might be too heavy for the network bandwidth.

### CPU pressure

A heavy workload might be preventing the Aurora storage daemon from getting sufficient CPU time.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Monitor your resources \(p. 1178\)](#)
- [Scale up the CPU \(p. 1179\)](#)
- [Increase network bandwidth \(p. 1179\)](#)
- [Reduce the number of commits \(p. 1179\)](#)

### Monitor your resources

To determine the cause of the increased `IO:XactSync` events, check the following metrics:

- `WriteThroughput` and `CommitThroughput` – Changes in write throughput or commit throughput can show an increase in workload.
- `WriteLatency` and `CommitLatency` – Changes in write latency or commit latency can show that the storage subsystem is being asked to do more work.
- `CPUUtilization` – If the instance's CPU utilization is above 90 percent, the Aurora storage daemon might not be getting sufficient time on the CPU. In this case, I/O performance degrades.

For information about these metrics, see [Instance-level metrics for Amazon Aurora \(p. 531\)](#).

## Scale up the CPU

To address CPU starvation issues, consider changing to an instance type with more CPU capacity. For information about CPU capacity for a DB instance class, see [Hardware specifications for DB instance classes for Aurora \(p. 64\)](#).

## Increase network bandwidth

To determine whether the instance is reaching its network bandwidth limits, check for the following other wait events:

- `IO:DataFileRead`, `IO:BufferRead`, `IO:BufferWrite`, and `IO:XactWrite` – Queries using large amounts of I/O can generate more of these wait events.
- `Client:ClientRead` and `Client:ClientWrite` – Queries with large amounts of client communication can generate more of these wait events.

If network bandwidth is an issue, consider changing to an instance type with more network bandwidth. For information about network performance for a DB instance class, see [Hardware specifications for DB instance classes for Aurora \(p. 64\)](#).

## Reduce the number of commits

To reduce the number of commits, combine statements into transaction blocks.

## ipc:damrecordtxack

The `ipc:damrecordtxack` event occurs when Aurora PostgreSQL in a session using database activity streams generates an activity stream event, then waits for that event to become durable.

### Topics

- [Relevant engine versions \(p. 1179\)](#)
- [Context \(p. 1179\)](#)
- [Causes \(p. 1179\)](#)
- [Actions \(p. 1179\)](#)

## Relevant engine versions

This wait event information is relevant for all Aurora PostgreSQL 10.7 and higher 10 versions, 11.4 and higher 11 versions, and all 12 and 13 versions.

## Context

In synchronous mode, durability of activity stream events is favored over database performance. While waiting for a durable write of the event, the session blocks other database activity, causing the `ipc:damrecordtxack` wait event.

## Causes

The most common cause for the `ipc:damrecordtxack` event to appear in top waits is that the Database Activity Streams (DAS) feature is a holistic audit. Higher SQL activity generates activity stream events that need to be recorded.

## Actions

We recommend different actions depending on the causes of your wait event:

- Reduce the number of SQL statements or turn off database activity streams. Doing this reduces the number of events that require durable writes.
- Change to asynchronous mode. Doing this helps to reduce contention on the `ipc:damrecordtxack` wait event.

However, the DAS feature can't guarantee the durability of every event in asynchronous mode.

## Lock:advisory

The `Lock:advisory` event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.

### Topics

- [Relevant engine versions \(p. 1180\)](#)
- [Context \(p. 1180\)](#)
- [Causes \(p. 1180\)](#)
- [Actions \(p. 1181\)](#)

## Relevant engine versions

This wait event information is relevant for Aurora PostgreSQL versions 9.6 and higher.

## Context

PostgreSQL advisory locks are application-level, cooperative locks explicitly locked and unlocked by the user's application code. An application can use PostgreSQL advisory locks to coordinate activity across multiple sessions. Unlike regular, object- or row-level locks, the application has full control over the lifetime of the lock. For more information, see [Advisory Locks](#) in the PostgreSQL documentation.

Advisory locks can be released before a transaction ends or be held by a session across transactions. This isn't true for implicit, system-enforced locks, such as an access-exclusive lock on a table acquired by a `CREATE INDEX` statement.

For a description of the functions used to acquire (lock) and release (unlock) advisory locks, see [Advisory Lock Functions](#) in the PostgreSQL documentation.

Advisory locks are implemented on top of the regular PostgreSQL locking system and are visible in the `pg_locks` system view.

## Causes

This lock type is exclusively controlled by an application explicitly using it. Advisory locks that are acquired for each row as part of a query can cause a spike in locks or a long-term buildup.

These effects happen when the query is run in a way that acquires locks on more rows than are returned by the query. The application must eventually release every lock, but if locks are acquired on rows that aren't returned, the application can't find all of the locks.

The following example is from [Advisory Locks](#) in the PostgreSQL documentation.

```
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100;
```

In this example, the `LIMIT` clause can only stop the query's output after the rows have already been internally selected and their ID values locked. This can happen suddenly when a growing data volume causes the planner to choose a different execution plan that wasn't tested during development. The buildup in this case happens because the application explicitly calls `pg_advisory_unlock` for every ID value that was locked. However, in this case it can't find the set of locks acquired on rows that weren't returned. Because the locks are acquired on the session level, they aren't released automatically at the end of the transaction.

Another possible cause for spikes in blocked lock attempts is unintended conflicts. In these conflicts, unrelated parts of the application share the same lock ID space by mistake.

## Actions

Review application usage of advisory locks and detail where and when in the application flow each type of advisory lock is acquired and released.

Determine whether a session is acquiring too many locks or a long-running session isn't releasing locks early enough, leading to a slow buildup of locks. You can correct a slow buildup of session-level locks by ending the session using `pg_terminate_backend(pid)`.

A client waiting for an advisory lock appears in `pg_stat_activity` with `wait_event_type=Lock` and `wait_event=advisory`. You can obtain specific lock values by querying the `pg_locks` system view for the same `pid`, looking for `locktype=advisory` and `granted=f`.

You can then identify the blocking session by querying `pg_locks` for the same advisory lock having `granted=t`, as shown in the following example.

```

SELECT blocked_locks.pid AS blocked_pid,
       blocking_locks.pid AS blocking_pid,
       blocked_activity.username AS blocked_user,
       blocking_activity.username AS blocking_user,
       now() - blocked_activity.xact_start AS blocked_transaction_duration,
       now() - blocking_activity.xact_start AS blocking_transaction_duration,
       concat(blocked_activity.wait_event_type,':',blocked_activity.wait_event) AS
blocked_wait_event,
       concat(blocking_activity.wait_event_type,':',blocking_activity.wait_event) AS
blocking_wait_event,
       blocked_activity.state AS blocked_state,
       blocking_activity.state AS blocking_state,
       blocked_locks.locktype AS blocked_locktype,
       blocking_locks.locktype AS blocking_locktype,
       blocked_activity.query AS blocked_statement,
       blocking_activity.query AS blocking_statement
  FROM pg_catalog.pg_locks blocked_locks
 JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid =
blocked_locks.pid

   AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
   AND blocking_locks.transactionid IS NOT DISTINCT FROM blocked_locks.transactionid
   AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
   AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
   AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
   AND blocking_locks.pid != blocked_locks.pid
 JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid =
blocking_locks.pid
 WHERE NOT blocked_locks.GRANTED;

```

All of the advisory lock API functions have two sets of arguments, either one `bigint` argument or two `integer` arguments:

- For the API functions with one `bigint` argument, the upper 32 bits are in `pg_locks.classid` and the lower 32 bits are in `pg_locks.objid`.
- For the API functions with two `integer` arguments, the first argument is `pg_locks.classid` and the second argument is `pg_locks.objid`.

The `pg_locks.objsubid` value indicates which API form was used: 1 means one `bigint` argument; 2 means two `integer` arguments.

## Lock:extend

The `Lock:extend` event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

### Topics

- [Supported engine versions \(p. 1182\)](#)
- [Context \(p. 1182\)](#)
- [Likely causes of increased waits \(p. 1182\)](#)
- [Actions \(p. 1182\)](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

The event `Lock:extend` indicates that a backend process is waiting to extend a relation that another backend process holds a lock on while it's extending that relation. Because only one process at a time can extend a relation, the system generates a `Lock:extend` wait event. `INSERT`, `COPY`, and `UPDATE` operations can generate this event.

## Likely causes of increased waits

When the `Lock:extend` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

### Surge in concurrent inserts or updates to the same table

There might be an increase in the number of concurrent sessions with queries that insert into or update the same table.

### Insufficient network bandwidth

The network bandwidth on the DB instance might be insufficient for the storage communication needs of the current workload. This can contribute to storage latency that causes an increase in `Lock:extend` events.

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Reduce concurrent inserts and updates to the same relation \(p. 1183\)](#)
- [Increase network bandwidth \(p. 1183\)](#)

## Reduce concurrent inserts and updates to the same relation

First, determine whether there's an increase in `tup_inserted` and `tup_updated` metrics and an accompanying increase in this wait event. If so, check which relations are in high contention for insert and update operations. To determine this, query the `pg_stat_all_tables` view for the values in `n_tup_ins` and `n_tup_upd` fields. For information about the `pg_stat_all_tables` view, see [pg\\_stat\\_all\\_tables](#) in the PostgreSQL documentation.

To get more information about blocking and blocked queries, query `pg_stat_activity` as in the following example:

```
SELECT
    blocked.pid,
    blocked.username,
    blocked.query,
    blocking.pid AS blocking_id,
    blocking.query AS blocking_query,
    blocking.wait_event AS blocking_wait_event,
    blocking.wait_event_type AS blocking_wait_event_type
FROM pg_stat_activity AS blocked
JOIN pg_stat_activity AS blocking ON blocking.pid = ANY(pg_blocking_pids(blocked.pid))
where
blocked.wait_event = 'extend'
and blocked.wait_event_type = 'Lock';

      pid | username |           query           | blocking_id | 
blocking_query          | blocking_wait_event | blocking_wait_event_type
-----+-----+-----+-----+
+-----+-----+-----+
+-----+
    7143 | myuser   | insert into tab1 values (1); |       4600 | INSERT INTO tab1 (a)
SELECT s FROM generate_series(1,1000000) s; | DataFileExtend     | IO
```

After you identify relations that contribute to increase `Lock:extend` events, use the following techniques to reduce the contention:

- Find out whether you can use partitioning to reduce contention for the same table. Separating inserted or updated tuples into different partitions can reduce contention. For information about partitioning, see [Managing PostgreSQL partitions with the pg\\_partman extension \(p. 1333\)](#).
- If the wait event is mainly due to update activity, consider reducing the relation's `fillfactor` value. This can reduce requests for new blocks during the update. The `fillfactor` is a storage parameter for a table that determines the maximum amount of space for packing a table page. It's expressed as a percentage of the total space for a page. For more information about the `fillfactor` parameter, see [CREATE TABLE](#) in the PostgreSQL documentation.

### Important

We highly recommend that you test your system if you change the `fillfactor` because changing this value can negatively impact performance, depending on your workload.

## Increase network bandwidth

To see whether there's an increase in write latency, check the `WriteLatency` metric in CloudWatch. If there is, use the `WriteThroughput` and `ReadThroughput` Amazon CloudWatch metrics to monitor the

storage related traffic on the DB cluster. These metrics can help you to determine if network bandwidth is sufficient for the storage activity of your workload.

If your network bandwidth isn't enough, increase it. If your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see [Amazon CloudWatch metrics for Amazon Aurora \(p. 525\)](#). For information about network performance for each DB instance class, see [Hardware specifications for DB instance classes for Aurora \(p. 64\)](#).

## Lock:Relation

The `Lock : Relation` event occurs when a query is waiting to acquire a lock on a table or view (relation) that's currently locked by another transaction.

### Topics

- [Supported engine versions \(p. 1184\)](#)
- [Context \(p. 1184\)](#)
- [Likely causes of increased waits \(p. 1185\)](#)
- [Actions \(p. 1185\)](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

Most PostgreSQL commands implicitly use locks to control concurrent access to data in tables. You can also use these locks explicitly in your application code with the `LOCK` command. Many lock modes aren't compatible with each other, and they can block transactions when they're trying to access the same object. When this happens, Aurora PostgreSQL generates a `Lock:Relation` event. Some common examples are the following:

- Exclusive locks such as `ACCESS EXCLUSIVE` can block all concurrent access. Data definition language (DDL) operations such as `DROP TABLE`, `TRUNCATE`, `VACUUM FULL`, and `CLUSTER` acquire `ACCESS EXCLUSIVE` locks implicitly. `ACCESS EXCLUSIVE` is also the default lock mode for `LOCK TABLE` statements that don't specify a mode explicitly.
- Using `CREATE INDEX` (without `CONCURRENT`) on a table conflicts with data manipulation language (DML) statements `UPDATE`, `DELETE`, and `INSERT`, which acquire `ROW EXCLUSIVE` locks.

For more information about table-level locks and conflicting lock modes, see [Explicit Locking](#) in the PostgreSQL documentation.

Blocking queries and transactions typically unblock in one of the following ways:

- Blocking query – The application can cancel the query or the user can end the process. The engine can also force the query to end because of a session's statement-timeout or a deadlock detection mechanism.
- Blocking transaction – A transaction stops blocking when it runs a `ROLLBACK` or `COMMIT` statement. Rollbacks also happen automatically when sessions are disconnected by a client or by network issues, or are ended. Sessions can be ended when the database engine is shut down, when the system is out of memory, and so forth.

## Likely causes of increased waits

When the `Lock:Relation` event occurs more frequently than normal, it can indicate a performance issue. Typical causes include the following:

### Increased concurrent sessions with conflicting table locks

There might be an increase in the number of concurrent sessions with queries that lock the same table with conflicting locking modes.

### Maintenance operations

Health maintenance operations such as `VACUUM` and `ANALYZE` can significantly increase the number of conflicting locks. `VACUUM FULL` acquires an `ACCESS EXCLUSIVE` lock, and `ANALYZE` acquires a `SHARE UPDATE EXCLUSIVE` lock. Both types of locks can cause a `Lock:Relation` wait event. Application data maintenance operations such as refreshing a materialized view can also increase blocked queries and transactions.

### Locks on reader instances

There might be a conflict between the relation locks held by the writer and readers. Currently, only `ACCESS EXCLUSIVE` relation locks are replicated to reader instances. However, the `ACCESS EXCLUSIVE` relation lock will conflict with any `ACCESS SHARE` relation locks held by the reader. This can cause an increase in lock relation wait events on the reader.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Reduce the impact of blocking SQL statements \(p. 1185\)](#)
- [Minimize the effect of maintenance operations \(p. 1185\)](#)
- [Check for reader locks \(p. 1186\)](#)

### Reduce the impact of blocking SQL statements

To reduce the impact of blocking SQL statements, modify your application code where possible. Following are two common techniques for reducing blocks:

- Use the `NOWAIT` option – Some SQL commands, such as `SELECT` and `LOCK` statements, support this option. The `NOWAIT` directive cancels the lock-requesting query if the lock can't be acquired immediately. This technique can help prevent a blocking session from causing a pile-up of blocked sessions behind it.

For example: Assume that transaction A is waiting on a lock held by transaction B. Now, if B requests a lock on a table that's locked by transaction C, transaction A might be blocked until transaction C completes. But if transaction B uses a `NOWAIT` when it requests the lock on C, it can fail fast and ensure that transaction A doesn't have to wait indefinitely.

- Use `SET lock_timeout` – Set a `lock_timeout` value to limit the time a SQL statement waits to acquire a lock on a relation. If the lock isn't acquired within the timeout specified, the transaction requesting the lock is cancelled. Set this value at the session level.

### Minimize the effect of maintenance operations

Maintenance operations such as `VACUUM` and `ANALYZE` are important. We recommend that you don't turn them off because you find `Lock:Relation` wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours.
- To reduce Lock:Relation waits caused by autovacuum tasks, perform any needed autovacuum tuning. For information about tuning autovacuum, see [Working with PostgreSQL autovacuum on Amazon RDS](#) in the *Amazon RDS User Guide*.

## Check for reader locks

You can see how concurrent sessions on a writer and readers might be holding locks that block each other. One way to do this is by running queries that return the lock type and relation. In the table you can find a sequence of queries to two such concurrent sessions, a writer session (left-hand column) and a reader session (right-hand column).

The replay process waits for the duration of `max_standby_streaming_delay` before cancelling the reader query. As shown in the example, the lock timeout of 100ms is well below the default `max_standby_streaming_delay` of 30 seconds. The lock times out before it's an issue.

Writer session	Reader session
<pre>export WRITER=aurorapg1.12345678910.us-west-1.rds.amazonaws.com psql -h \$WRITER psql (15devel, server 10.14) Type "help" for help.</pre>	<pre>export READER=aurorapg2.12345678910.us-west-1.rds.amazonaws.com psql -h \$READER psql (15devel, server 10.14) Type "help" for help.</pre>

The writer session creates table `t1` on the writer instance. The ACCESS EXCLUSIVE lock is acquired on the writer immediately, assuming that there are no conflicting queries on the writer.

```
postgres=> CREATE TABLE t1(b integer);
CREATE TABLE
```

The reader session sets a lock timeout interval of 100 milliseconds.

```
postgres=> SET lock_timeout=100;
SET
```

The reader session tries to read data from table `t1` on the reader instance.

```
postgres=> SELECT * FROM t1;
 b
 ---
 (0 rows)
```

The writer session drops `t1`.

```
postgres=> BEGIN;
BEGIN
postgres=> DROP TABLE t1;
DROP TABLE
postgres=>
```

The query times out and is canceled on the reader.

```
postgres=> SELECT * FROM t1;
ERROR: canceling statement due to lock timeout
```

**Writer session**

**Reader session**

```
LINE 1: SELECT * FROM t1;  
^
```

The reader session queries pg\_locks and pg\_stat\_activity to determine the cause of the error. The result indicates that the aurora wal replay process is holding an ACCESS EXCLUSIVE lock on table t1.

```
postgres=> SELECT locktype, relation, mode,  
    backend_type  
postgres-> FROM pg_locks l, pg_stat_activity t1  
postgres-> WHERE l.pid=t1.pid AND relation =  
  't1'::regclass::oid;  
locktype | relation | mode |  
backend_type  
-----+-----+-----+  
+-----+-----+-----+  
relation | 68628525 | AccessExclusiveLock |  
aurora wal replay  
(1 row)
```

## Lock:transactionid

The Lock:transactionid event occurs when a transaction is waiting for a row-level lock.

### Topics

- [Supported engine versions \(p. 1187\)](#)
- [Context \(p. 1187\)](#)
- [Likely causes of increased waits \(p. 1188\)](#)
- [Actions \(p. 1188\)](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

The event Lock:transactionid occurs when a transaction is trying to acquire a row-level lock that has already been granted to a transaction that is running at the same time. The session that shows the Lock:transactionid wait event is blocked because of this lock. After the blocking transaction ends in either a COMMIT or ROLLBACK statement, the blocked transaction can proceed.

The multiversion concurrency control semantics of Aurora PostgreSQL guarantee that readers don't block writers and writers don't block readers. For row-level conflicts to occur, blocking and blocked transactions must issue conflicting statements of the following types:

- UPDATE
- SELECT ... FOR UPDATE
- SELECT ... FOR KEY SHARE

The statement SELECT ... FOR KEY SHARE is a special case. The database uses the clause FOR KEY SHARE to optimize the performance of referential integrity. A row-level lock on a row can block INSERT, UPDATE, and DELETE commands on other tables that reference the row.

## Likely causes of increased waits

When this event appears more than normal, the cause is typically UPDATE, SELECT ... FOR UPDATE, or SELECT ... FOR KEY SHARE statements combined with the following conditions.

### Topics

- [High concurrency \(p. 1188\)](#)
- [Idle in transaction \(p. 1188\)](#)
- [Long-running transactions \(p. 1188\)](#)

### High concurrency

Aurora PostgreSQL can use granular row-level locking semantics. The probability of row-level conflicts increases when the following conditions are met:

- A highly concurrent workload contends for the same rows.
- Concurrency increases.

### Idle in transaction

Sometimes the pg\_stat\_activity.state column shows the value idle in transaction. This value appears for sessions that have started a transaction, but haven't yet issued a COMMIT or ROLLBACK. If the pg\_stat\_activity.state value isn't active, the query shown in pg\_stat\_activity is the most recent one to finish running. The blocking session isn't actively processing a query because an open transaction is holding a lock.

If an idle transaction acquired a row-level lock, it might be preventing other sessions from acquiring it. This condition leads to frequent occurrence of the wait event Lock:transactionid. To diagnose the issue, examine the output from pg\_stat\_activity and pg\_locks.

### Long-running transactions

Transactions that run for a long time get locks for a long time. These long-held locks can block other transactions from running.

## Actions

Row-locking is a conflict among UPDATE, SELECT ... FOR UPDATE, or SELECT ... FOR KEY SHARE statements. Before attempting a solution, find out when these statements are running on the same row. Use this information to choose a strategy described in the following sections.

### Topics

- [Respond to high concurrency \(p. 1188\)](#)
- [Respond to idle transactions \(p. 1189\)](#)
- [Respond to long-running transactions \(p. 1189\)](#)

### Respond to high concurrency

If concurrency is the issue, try one of the following techniques:

- Lower the concurrency in the application. For example, decrease the number of active sessions.

- Implement a connection pool. To learn how to pool connections with RDS Proxy, see [Using Amazon RDS Proxy \(p. 1430\)](#).
- Design the application or data model to avoid contending UPDATE and SELECT ... FOR UPDATE statements. You can also decrease the number of foreign keys accessed by SELECT ... FOR KEY SHARE statements.

## Respond to idle transactions

If pg\_stat\_activity.state shows idle in transaction, use the following strategies:

- Turn on autocommit wherever possible. This approach prevents transactions from blocking other transactions while waiting for a COMMIT or ROLLBACK.
- Search for code paths that are missing COMMIT, ROLLBACK, or END.
- Make sure that the exception handling logic in your application always has a path to a valid end of transaction.
- Make sure that your application processes query results after ending the transaction with COMMIT or ROLLBACK.

## Respond to long-running transactions

If long-running transactions are causing the frequent occurrence of Lock:transactionid, try the following strategies:

- Keep row locks out of long-running transactions.
- Limit the length of queries by implementing autocommit whenever possible.

# Lock:tuple

The Lock:tuple event occurs when a backend process is waiting to acquire a lock on a tuple.

## Topics

- [Supported engine versions \(p. 1189\)](#)
- [Context \(p. 1189\)](#)
- [Likely causes of increased waits \(p. 1190\)](#)
- [Actions \(p. 1190\)](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

The event Lock:tuple indicates that a backend is waiting to acquire a lock on a tuple while another backend holds a conflicting lock on the same tuple. The following table illustrates a scenario in which sessions generate the Lock:tuple event.

Time	Session 1	Session 2	Session 3
t1	Starts a transaction.		

Time	Session 1	Session 2	Session 3
t2	Updates row 1.		
t3		Updates row 1. The session acquires an exclusive lock on the tuple and then waits for session 1 to release the lock by committing or rolling back.	
t4			Updates row 1. The session waits for session 2 to release the exclusive lock on the tuple.

Or you can simulate this wait event by using the benchmarking tool `pgbench`. Configure a high number of concurrent sessions to update the same row in a table with a custom SQL file.

To learn more about conflicting lock modes, see [Explicit Locking](#) in the PostgreSQL documentation. To learn more about `pgbench`, see [pgbench](#) in the PostgreSQL documentation.

## Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A high number of concurrent sessions are trying to acquire a conflicting lock for the same tuple by running `UPDATE` or `DELETE` statements.
- Highly concurrent sessions are running a `SELECT` statement using the `FOR UPDATE` or `FOR NO KEY UPDATE` lock modes.
- Various factors drive application or connection pools to open more sessions to execute the same operations. As new sessions are trying to modify the same rows, DB load can spike, and `Lock:tuple` can appear.

For more information, see [Row-Level Locks](#) in the PostgreSQL documentation.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Investigate your application logic \(p. 1190\)](#)
- [Find the blocker session \(p. 1191\)](#)
- [Reduce concurrency when it is high \(p. 1191\)](#)
- [Troubleshoot bottlenecks \(p. 1192\)](#)

### Investigate your application logic

Find out whether a blocker session has been in the `idle in transaction` state for long time. If so, consider ending the blocker session as a short-term solution. You can use the `pg_terminate_backend` function. For more information about this function, see [Server Signaling Functions](#) in the PostgreSQL documentation.

For a long-term solution, do the following:

- Adjust the application logic.
- Use the `idle_in_transaction_session_timeout` parameter. This parameter ends any session with an open transaction that has been idle for longer than the specified amount of time. For more information, see [Client Connection Defaults](#) in the PostgreSQL documentation.
- Use autocommit as much as possible. For more information, see [SET AUTOCOMMIT](#) in the PostgreSQL documentation.

## Find the blocker session

While the `Lock:tuple` wait event is occurring, identify the blocker and blocked session by finding out which locks depend on one another. For more information, see [Lock dependency information](#) in the PostgreSQL wiki. To analyze past `Lock:tuple` events, use the Aurora function `aurora_stat_backend_waits`.

The following example queries all sessions, filtering on `tuple` and ordering by `wait_time`.

```
--AURORA_STAT_BACKEND_WAITS
    SELECT a.pid,
           a.username,
           a.app_name,
           a.current_query,
           a.current_wait_type,
           a.current_wait_event,
           a.current_state,
           wt.type_name AS wait_type,
           we.event_name AS wait_event,
           a.waits,
           a.wait_time
      FROM (SELECT pid,
                  username,
                  left(application_name,16) AS app_name,
                  coalesce(wait_event_type,'CPU') AS current_wait_type,
                  coalesce(wait_event,'CPU') AS current_wait_event,
                  state AS current_state,
                  left(query,80) as current_query,
                  (aurora_stat_backend_waits(pid)).*
             FROM pg_stat_activity
            WHERE pid <> pg_backend_pid()
              AND username<>'rdsadmin') a
  NATURAL JOIN aurora_stat_wait_type() wt
  NATURAL JOIN aurora_stat_wait_event() we
 WHERE we.event_name = 'tuple'
 ORDER BY a.wait_time;

pid | username | app_name | current_query | current_wait_type | current_wait_event | current_state | wait_type | wait_event | waits | wait_time
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+
 32136 | sys      | psql      | /*session3*/ update tab set col=1 where col=1; | Lock
         | tuple     | active     | Lock       | tuple        | 1 | 1000018
 11999 | sys      | psql      | /*session4*/ update tab set col=1 where col=1; | Lock
         | tuple     | active     | Lock       | tuple        | 1 | 1000024
```

## Reduce concurrency when it is high

The `Lock:tuple` event might occur constantly, especially in a busy workload time. In this situation, consider reducing the high concurrency for very busy rows. Often, just a few rows control a queue or the Boolean logic, which makes these rows very busy.

You can reduce concurrency by using different approaches based in the business requirement, application logic, and workload type. For example, you can do the following:

- Redesign your table and data logic to reduce high concurrency.
- Change the application logic to reduce high concurrency at the row level.
- Leverage and redesign queries with row-level locks.
- Use the `NOWAIT` clause with retry operations.
- Consider using optimistic and hybrid-locking logic concurrency control.
- Consider changing the database isolation level.

## Troubleshoot bottlenecks

The `Lock:tuple` can occur with bottlenecks such as CPU starvation or maximum usage of Amazon EBS bandwidth. To reduce bottlenecks, consider the following approaches:

- Scale up your instance class type.
- Optimize resource-intensive queries.
- Change the application logic.
- Archive data that is rarely accessed.

## lwlock:buffer\_content (BufferContent)

The `lwlock:buffer_content` event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing. In Aurora PostgreSQL 13 and higher, this wait event is called `BufferContent`.

### Topics

- [Supported engine versions \(p. 1192\)](#)
- [Context \(p. 1192\)](#)
- [Likely causes of increased waits \(p. 1192\)](#)
- [Actions \(p. 1193\)](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

To read or manipulate data, PostgreSQL accesses it through shared memory buffers. To read from the buffer, a process gets a lightweight lock (LWLock) on the buffer content in shared mode. To write to the buffer, it gets that lock in exclusive mode. Shared locks allow other processes to concurrently acquire shared locks on that content. Exclusive locks prevent other processes from getting any type of lock on it.

The `lwlock:buffer_content (BufferContent)` event indicates that multiple processes are attempting to get a lock on contents of a specific buffer.

## Likely causes of increased waits

When the `lwlock:buffer_content (BufferContent)` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

### Increased concurrent updates to the same data

There might be an increase in the number of concurrent sessions with queries that update the same buffer content. This contention can be more pronounced on tables with a lot of indexes.

### Workload data is not in memory

When data that the active workload is processing is not in memory, these wait events can increase. This effect is because processes holding locks can keep them longer while they perform disk I/O operations.

### Excessive use of foreign key constraints

Foreign key constraints can increase the amount of time a process holds onto a buffer content lock. This effect is because read operations require a shared buffer content lock on the referenced key while that key is being updated.

## Actions

We recommend different actions depending on the causes of your wait event. You might identify `llock:buffer_content` (`BufferContent`) events by using Amazon RDS Performance Insights or by querying the view `pg_stat_activity`.

### Topics

- [Improve in-memory efficiency \(p. 1193\)](#)
- [Reduce usage of foreign key constraints \(p. 1193\)](#)
- [Remove unused indexes \(p. 1193\)](#)

### Improve in-memory efficiency

To increase the chance that active workload data is in memory, partition tables or scale up your instance class. For information about DB instance classes, see [Aurora DB instance classes \(p. 56\)](#).

### Reduce usage of foreign key constraints

Investigate workloads experiencing high numbers of `llock:buffer_content` (`BufferContent`) wait events for usage of foreign key constraints. Remove unnecessary foreign key constraints.

### Remove unused indexes

For workloads experiencing high numbers of `llock:buffer_content` (`BufferContent`) wait events, identify unused indexes and remove them.

## LWLock:buffer\_mapping

This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.

### Note

This event appears as `LWLock:buffer_mapping` in Aurora PostgreSQL version 12 and lower, and `LWLock:BufferMapping` in version 13 and higher.

### Topics

- [Supported engine versions \(p. 1194\)](#)
- [Context \(p. 1194\)](#)
- [Causes \(p. 1194\)](#)
- [Actions \(p. 1194\)](#)

## Supported engine versions

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

### Context

The *shared buffer pool* is an Aurora PostgreSQL memory area that holds all pages that are or were being used by processes. When a process needs a page, it reads the page into the shared buffer pool. The `shared_buffers` parameter sets the shared buffer size and reserves a memory area to store the table and index pages. If you change this parameter, make sure to restart the database. For more information, see [Shared buffers \(p. 1154\)](#).

The `LWLock:buffer_mapping` wait event occurs in the following scenarios:

- A process searches the buffer table for a page and acquires a shared buffer mapping lock.
- A process loads a page into the buffer pool and acquires an exclusive buffer mapping lock.
- A process removes a page from the pool and acquires an exclusive buffer mapping lock.

### Causes

When this event appears more than normal, possibly indicating a performance problem, the database is paging in and out of the shared buffer pool. Typical causes include the following:

- Large queries
- Bloated indexes and tables
- Full table scans
- A shared pool size that is smaller than the working set

### Actions

We recommend different actions depending on the causes of your wait event.

#### Topics

- [Monitor buffer-related metrics \(p. 1194\)](#)
- [Assess your indexing strategy \(p. 1195\)](#)
- [Reduce the number of buffers that must be allocated quickly \(p. 1195\)](#)

#### Monitor buffer-related metrics

When `LWLock:buffer_mapping` waits spike, investigate the buffer hit ratio. You can use these metrics to get a better understanding of what is happening in the buffer cache. Examine the following metrics:

`BufferCacheHitRatio`

This Amazon CloudWatch metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB cluster. You might see this metric decrease in the lead-up to the `LWLock:buffer_mapping` wait event.

`blks_hit`

This Performance Insights counter metric indicates the number of blocks that were retrieved from the shared buffer pool. After the `LWLock:buffer_mapping` wait event appears, you might observe a spike in `blks_hit`.

### blks\_read

This Performance Insights counter metric indicates the number of blocks that required I/O to be read into the shared buffer pool. You might observe a spike in `blks_read` in the lead-up to the `LWLock:buffer_mapping` wait event.

## Assess your indexing strategy

To confirm that your indexing strategy is not degrading performance, check the following:

### Index bloat

Ensure that index and table bloat aren't leading to unnecessary pages being read into the shared buffer. If your tables contain unused rows, consider archiving the data and removing the rows from the tables. You can then rebuild the indexes for the resized tables.

### Indexes for frequently used queries

To determine whether you have the optimal indexes, monitor DB engine metrics in Performance Insights. The `tup_returned` metric shows the number of rows read. The `tup_fetched` metric shows the number of rows returned to the client. If `tup_returned` is significantly larger than `tup_fetched`, the data might not be properly indexed. Also, your table statistics might not be current.

## Reduce the number of buffers that must be allocated quickly

To reduce the `LWLock:buffer_mapping` wait events, try to reduce the number of buffers that must be allocated quickly. One strategy is to perform smaller batch operations. You might be able to achieve smaller batches by partitioning your tables.

## LWLock:BufferIO

The `LWLock:BufferIO` event occurs when Aurora PostgreSQL or RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page. Its purpose is for the same page to be read into the shared buffer.

### Topics

- [Relevant engine versions \(p. 1195\)](#)
- [Context \(p. 1195\)](#)
- [Causes \(p. 1196\)](#)
- [Actions \(p. 1196\)](#)

## Relevant engine versions

This wait event information is relevant for all Aurora PostgreSQL 13 versions.

## Context

Each shared buffer has an I/O lock that is associated with the `LWLock:BufferIO` wait event, each time a block (or a page) has to be retrieved outside the shared buffer pool.

This lock is used to handle multiple sessions that all require access to the same block. This block has to be read from outside the shared buffer pool, defined by the `shared_buffers` parameter.

As soon as the page is read inside the shared buffer pool, the `LWLock:BufferIO` lock is released.

**Note**

The `LWLock:BufferIO` wait event precedes the [IO:DataFileRead \(p. 1171\)](#) wait event. The `IO:DataFileRead` wait event occurs while data is being read from storage.

For more information on lightweight locks, see [Locking Overview](#).

## Causes

Common causes for the `LWLock:BufferIO` event to appear in top waits include the following:

- Multiple backends or connections trying to access the same page that's also pending an I/O operation
- The ratio between the size of the shared buffer pool (defined by the `shared_buffers` parameter) and the number of buffers needed by the current workload
- The size of the shared buffer pool not being well balanced with the number of pages being evicted by other operations
- Large or bloated indexes that require the engine to read more pages than necessary into the shared buffer pool
- Lack of indexes that forces the DB engine to read more pages from the tables than necessary
- Checkpoints occurring too frequently or needing to flush too many modified pages
- Sudden spikes for database connections trying to perform operations on the same page

## Actions

We recommend different actions depending on the causes of your wait event:

- Observe Amazon CloudWatch metrics for correlation between sharp decreases in the `BufferCacheHitRatio` and `LWLock:BufferIO` wait events. This effect can mean that you have a small `shared_buffers` setting. You might need to increase it or scale up your DB instance class. You can split your workload into more reader nodes.
- Tune `max_wal_size` and `checkpoint_timeout` based on your workload peak time if you see `LWLock:BufferIO` coinciding with `BufferCacheHitRatio` metric dips. Then identify which query might be causing it.
- Verify whether you have unused indexes, then remove them.
- Use partitioned tables (which also have partitioned indexes). Doing this helps to keep index reordering low and reduces its impact.
- Avoid indexing columns unnecessarily.
- Prevent sudden database connection spikes by using a connection pool.
- Restrict the maximum number of connections to the database as a best practice.

## LWLock:lock\_manager

This event occurs when the Aurora PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.

**Topics**

- [Supported engine versions \(p. 1197\)](#)
- [Context \(p. 1197\)](#)
- [Likely causes of increased waits \(p. 1197\)](#)
- [Actions \(p. 1198\)](#)

## Supported engine versions

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

### Context

When you issue a SQL statement, Aurora PostgreSQL records locks to protect the structure, data, and integrity of your database during concurrent operations. The engine can achieve this goal using a fast path lock or a path lock that isn't fast. A path lock that isn't fast is more expensive and creates more overhead than a fast path lock.

#### Fast path locking

To reduce the overhead of locks that are taken and released frequently, but that rarely conflict, backend processes can use fast path locking. The database uses this mechanism for locks that meet the following criteria:

- They use the DEFAULT lock method.
- They represent a lock on a database relation rather than a shared relation.
- They are weak locks that are unlikely to conflict.
- The engine can quickly verify that no conflicting locks can possibly exist.

The engine can't use fast path locking when either of the following conditions is true:

- The lock doesn't meet the preceding criteria.
- No more slots are available for the backend process.

For more information about fast path locking, see [fast path](#) in the PostgreSQL lock manager README and [pg-locks](#) in the PostgreSQL documentation.

#### Example of a scaling problem for the lock manager

In this example, a table named `purchases` stores five years of data, partitioned by day. Each partition has two indexes. The following sequence of events occurs:

1. You query many days worth of data, which requires the database to read many partitions.
2. The database creates a lock entry for each partition. If partition indexes are part of the optimizer access path, the database creates a lock entry for them, too.
3. When the number of requested locks entries for the same backend process is higher than 16, which is the value of `FP_LOCK_SLOTS_PER_BACKEND`, the lock manager uses the non-fast path lock method.

Modern applications might have hundreds of sessions. If concurrent sessions are querying the parent without proper partition pruning, the database might create hundreds or even thousands of non-fast path locks. Typically, when this concurrency is higher than the number of vCPUs, the `LWLock:lock_manager` wait event appears.

#### Note

The `LWLock:lock_manager` wait event isn't related to the number of partitions or indexes in a database schema. Instead, it's related to the number of non-fast path locks that the database must control.

## Likely causes of increased waits

When the `LWLock:lock_manager` wait event occurs more than normal, possibly indicating a performance problem, the most likely causes of sudden spikes are as follows:

- Concurrent active sessions are running queries that don't use fast path locks. These sessions also exceed the maximum vCPU.
- A large number of concurrent active sessions are accessing a heavily partitioned table. Each partition has multiple indexes.
- The database is experiencing a connection storm. By default, some applications and connection pool software create more connections when the database is slow. This practice makes the problem worse. Tune your connection pool software so that connection storms don't occur.
- A large number of sessions query a parent table without pruning partitions.
- A data definition language (DDL), data manipulation language (DML), or a maintenance command exclusively locks either a busy relation or tuples that are frequently accessed or modified.

## Actions

If the CPU wait event occurs, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades and this wait event is dominating DB load.

### Topics

- [Use partition pruning \(p. 1198\)](#)
- [Remove unnecessary indexes \(p. 1198\)](#)
- [Tune your queries for fast path locking \(p. 1198\)](#)
- [Tune for other wait events \(p. 1199\)](#)
- [Reduce hardware bottlenecks \(p. 1199\)](#)
- [Use a connection pooler \(p. 1199\)](#)
- [Upgrade your Aurora PostgreSQL version \(p. 1199\)](#)

## Use partition pruning

*Partition pruning* is a query optimization strategy that excludes unneeded partitions from table scans, thereby improving performance. Partition pruning is turned on by default. If it is turned off, turn it on as follows.

```
SET enable_partition_pruning = on;
```

Queries can take advantage of partition pruning when their `WHERE` clause contains the column used for the partitioning. For more information, see [Partition Pruning](#) in the PostgreSQL documentation.

## Remove unnecessary indexes

Your database might contain unused or rarely used indexes. If so, consider deleting them. Do either of the following:

- Learn how to find unnecessary indexes by reading [Unused Indexes](#) in the PostgreSQL wiki.
- Run PG Collector. This SQL script gathers database information and presents it in a consolidated HTML report. Check the "Unused indexes" section. For more information, see [pg-collector](#) in the AWS Labs GitHub repository.

## Tune your queries for fast path locking

To find out whether your queries use fast path locking, query the `fastpath` column in the `pg_locks` table. If your queries aren't using fast path locking, try to reduce number of relations per query to fewer than 16.

## Tune for other wait events

If `LWLock:lock_manager` is first or second in the list of top waits, check whether the following wait events also appear in the list:

- `Lock:Relation`
- `Lock:transactionid`
- `Lock:tuple`

If the preceding events appear high in the list, consider tuning these wait events first. These events can be a driver for `LWLock:lock_manager`.

## Reduce hardware bottlenecks

You might have a hardware bottleneck, such as CPU starvation or maximum usage of your Amazon EBS bandwidth. In these cases, consider reducing the hardware bottlenecks. Consider the following actions:

- Scale up your instance class.
- Optimize queries that consume large amounts of CPU and memory.
- Change your application logic.
- Archive your data.

For more information about CPU, memory, and EBS network bandwidth, see [Amazon RDS Instance Types](#).

## Use a connection pooler

If your total number of active connections exceeds the maximum vCPU, more OS processes require CPU than your instance type can support. In this case, consider using or tuning a connection pool. For more information about the vCPUs for your instance type, see [Amazon RDS Instance Types](#).

For more information about connection pooling, see the following resources:

- [Using Amazon RDS Proxy \(p. 1430\)](#)
- [pgbouncer](#)
- [Connection Pools and Data Sources](#) in the *PostgreSQL Documentation*

## Upgrade your Aurora PostgreSQL version

If your current version of Aurora PostgreSQL is lower than 12, upgrade to version 12 or higher. PostgreSQL versions 12 and 13 have an improved partition mechanism. For more information about version 12, see [PostgreSQL 12.0 Release Notes](#). For more information about upgrading Aurora PostgreSQL, see [Amazon Aurora PostgreSQL updates \(p. 1413\)](#).

## Timeout:PgSleep

The `Timeout:PgSleep` event occurs when a server process has called the `pg_sleep` function and is waiting for the sleep timeout to expire.

### Topics

- [Supported engine versions \(p. 1200\)](#)
- [Likely causes of increased waits \(p. 1200\)](#)

- [Actions \(p. 1200\)](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Likely causes of increased waits

This wait event occurs when an application, stored function, or user issues a SQL statement that calls one of the following functions:

- `pg_sleep`
- `pg_sleep_for`
- `pg_sleep_until`

The preceding functions delay execution until the specified number of seconds have elapsed. For example, `SELECT pg_sleep(1)` pauses for 1 second. For more information, see [Delaying Execution](#) in the PostgreSQL documentation.

## Actions

Identify the statement that was running the `pg_sleep` function. Determine if the use of the function is appropriate.

# Best practices with Amazon Aurora PostgreSQL

Following, you can find several best practices for managing your Amazon Aurora PostgreSQL DB cluster. Be sure to also review basic maintenance tasks. For more information, see [Managing Amazon Aurora PostgreSQL \(p. 1143\)](#).

### Topics

- [Troubleshooting storage issues \(p. 1200\)](#)
- [Fast failover with Amazon Aurora PostgreSQL \(p. 1201\)](#)
- [Fast recovery after failover with cluster cache management for Aurora PostgreSQL \(p. 1208\)](#)
- [Managing Aurora PostgreSQL connection churn with pooling \(p. 1212\)](#)
- [Tuning memory parameters for Aurora PostgreSQL \(p. 1218\)](#)

## Troubleshooting storage issues

If the amount of memory required by a sort or index creation operation exceeds the amount of memory available, Aurora PostgreSQL writes the excess data to storage. When it writes the data, it uses the same storage space that it uses for storing error and message logs.

If your sorts or index creation functions exceed the memory available, you can run out of local storage. If you experience issues with Aurora PostgreSQL running out of storage space, you have a couple of options. You can either reconfigure your data sorts to use more memory, or reduce the data retention period for your PostgreSQL log files. For more information about changing the log retention period, see [PostgreSQL database log files \(p. 610\)](#).

If your Aurora cluster is larger than 40 TB, don't use db.t2, db.t3, or db.t4g instance classes.

## Fast failover with Amazon Aurora PostgreSQL

Following, you can learn how to make sure that failover occurs as fast as possible. To recover quickly after failover, you can use cluster cache management for your Aurora PostgreSQL DB cluster. For more information, see [Fast recovery after failover with cluster cache management for Aurora PostgreSQL \(p. 1208\)](#).

Some of the steps that you can take to make failover perform fast include the following:

- Set Transmission Control Protocol (TCP) keepalives with short time frames, to stop longer running queries before the read timeout expires if there's a failure.
- Set timeouts for Java Domain Name System (DNS) caching aggressively. Doing this helps ensure the Aurora read-only endpoint can properly cycle through read-only nodes on later connection attempts.
- Set the timeout variables used in the JDBC connection string as low as possible. Use separate connection objects for short- and long-running queries.
- Use the read and write Aurora endpoints that are provided to connect to the cluster.
- Use RDS API operations to test application response on server-side failures. Also, use a packet dropping tool to test application response for client-side failures.
- Use the AWS JDBC Driver for PostgreSQL (preview) to take full advantage of the failover capabilities of Aurora PostgreSQL. For more information about the AWS JDBC Driver for PostgreSQL and complete instructions for using it, see the [AWS JDBC Driver for PostgreSQL GitHub repository](#).

These are covered in more detail following.

### Topics

- [Setting TCP keepalives parameters \(p. 1201\)](#)
- [Configuring your application for fast failover \(p. 1202\)](#)
- [Testing failover \(p. 1205\)](#)
- [Fast failover example in Java \(p. 1206\)](#)

## Setting TCP keepalives parameters

When you set up a TCP connection, a set of timers is associated with the connection. When the keepalive timer reaches zero, a keepalive probe packet is sent to the connection endpoint. If the probe receives a reply, you can assume that the connection is still up and running.

Turning on TCP keepalive parameters and setting them aggressively ensures that if your client can't connect to the database, any active connections are quickly closed. The application can then connect to a new endpoint.

Make sure to set the following TCP keepalive parameters:

- `tcp_keepalive_time` controls the time, in seconds, after which a keepalive packet is sent when no data has been sent by the socket. ACKs aren't considered data. We recommend the following setting:

```
tcp_keepalive_time = 1
```

- `tcp_keepalive_intvl` controls the time, in seconds, between sending subsequent keepalive packets after the initial packet is sent. Set this time by using the `tcp_keepalive_time` parameter. We recommend the following setting:

```
tcp_keepalive_intvl = 1
```

- `tcp_keepalive_probes` is the number of unacknowledged keepalive probes that occur before the application is notified. We recommend the following setting:

```
tcp_keepalive_probes = 5
```

These settings should notify the application within five seconds when the database stops responding. If keepalive packets are often dropped within the application's network, you can set a higher `tcp_keepalive_probes` value. Doing this allows for more buffer in less reliable networks, although it increases the time that it takes to detect an actual failure.

### To set TCP keepalive parameters on Linux

1. Test how to configure your TCP keepalive parameters.

We recommend doing so by using the command line with the following commands. This suggested configuration is system-wide. In other words, it also affects all other applications that create sockets with the `SO_KEEPALIVE` option on.

```
sudo sysctl net.ipv4.tcp_keepalive_time=1
sudo sysctl net.ipv4.tcp_keepalive_intvl=1
sudo sysctl net.ipv4.tcp_keepalive_probes=5
```

2. After you've found a configuration that works for your application, persist these settings by adding the following lines to `/etc/sysctl.conf`, including any changes you made:

```
tcp_keepalive_time = 1
tcp_keepalive_intvl = 1
tcp_keepalive_probes = 5
```

## Configuring your application for fast failover

Following, you can find a discussion of several configuration changes for Aurora PostgreSQL that you can make for fast failover. To learn more about PostgreSQL JDBC driver setup and configuration, see the [PostgreSQL JDBC Driver](#) documentation.

### Topics

- [Reducing DNS cache timeouts \(p. 1202\)](#)
- [Setting an Aurora PostgreSQL connection string for fast failover \(p. 1202\)](#)
- [Other options for obtaining the host string \(p. 1204\)](#)

### Reducing DNS cache timeouts

When your application tries to establish a connection after a failover, the new Aurora PostgreSQL writer will be a previous reader. You can find it by using the Aurora read-only endpoint before DNS updates have fully propagated. Setting the java DNS time to live (TTL) to a low value, such as under 30 seconds, helps cycle between reader nodes on later connection attempts.

```
// Sets internal TTL to match the Aurora RO Endpoint TTL
java.security.Security.setProperty("networkaddress.cache.ttl" , "1");
// If the lookup fails, default to something like small to retry
java.security.Security.setProperty("networkaddress.cache.negative.ttl" , "3");
```

### Setting an Aurora PostgreSQL connection string for fast failover

To use Aurora PostgreSQL fast failover, make sure that your application's connection string has a list of hosts instead of just a single host. Following is an example connection string that you can use to connect to an Aurora PostgreSQL cluster. In this example, the hosts are in bold.

```
jdbc:postgresql://myauroracluster.cluster-c9bfei4hjlr.us-east-1-
beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hjlr.us-east-1-beta.rds.amazonaws.com:5432
/postgres?user=<primaryuser>&password=<primarypw>&loginTimeout=2
&connectTimeout=2&cancelSignalTimeout=2&socketTimeout=60
&tcpKeepAlive=true&targetServerType=primary
```

For best availability and to avoid a dependency on the RDS API, we recommend that you maintain a file to connect with. This file contains a host string that your application reads from when you establish a connection to the database. This host string has all the Aurora endpoints available for the cluster. For more information about Aurora endpoints, see [Amazon Aurora connection management \(p. 35\)](#).

For example, you might store your endpoints in a local file as shown following.

```
myauroracluster.cluster-c9bfei4hjlr.us-east-1-beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hjlr.us-east-1-beta.rds.amazonaws.com:5432
```

Your application reads from this file to populate the host section of the JDBC connection string. Renaming the DB cluster causes these endpoints to change. Make sure that your application handles this event if it occurs.

Another option is to use a list of DB instance nodes, as follows.

```
my-node1.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node2.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node3.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node4.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432
```

The benefit of this approach is that the PostgreSQL JDBC connection driver loops through all nodes on this list to find a valid connection. In contrast, when you use the Aurora endpoints only two nodes are tried in each connection attempt. However, there's a downside to using DB instance nodes. If you add or remove nodes from your cluster and the list of instance endpoints becomes stale, the connection driver might never find the correct host to connect to.

To help ensure that your application doesn't wait too long to connect to any one host, set the following parameters aggressively:

- `targetServerType` – Controls whether the driver connects to a write or read node. To ensure that your applications reconnect only to a write node, set the `targetServerType` value to `primary`.  
Values for the `targetServerType` parameter include `primary`, `secondary`, `any`, and `preferSecondary`. The `preferSecondary` value attempts to establish a connection to a reader first. It connects to the writer if no reader connection can be established.
- `loginTimeout` – Controls how long your application waits to log in to the database after a socket connection has been established.
- `connectTimeout` – Controls how long the socket waits to establish a connection to the database.

You can modify other application parameters to speed up the connection process, depending on how aggressive you want your application to be:

- `cancelSignalTimeout` – In some applications, you might want to send a "best effort" cancel signal on a query that has timed out. If this cancel signal is in your failover path, consider setting it aggressively to avoid sending this signal to a dead host.
- `socketTimeout` – This parameter controls how long the socket waits for read operations. This parameter can be used as a global "query timeout" to ensure no query waits longer than this value. A good practice is to have two connection handlers. One connection handler runs short-lived queries and sets this value lower. Another connection handler, for long-running queries, has this value set much

higher. With this approach, you can rely on TCP keepalive parameters to stop long-running queries if the server goes down.

- `tcpKeepAlive` – Turn on this parameter to ensure the TCP keepalive parameters that you set are respected.
- `loadBalanceHosts` – When set to `true`, this parameter has the application connect to a random host chosen from a list of candidate hosts.

## Other options for obtaining the host string

You can get the host string from several sources, including the `aurora_replica_status` function and by using the Amazon RDS API.

In many cases, you need to determine who the writer of the cluster is or to find other reader nodes in the cluster. To do this, your application can connect to any DB instance in the DB cluster and query the `aurora_replica_status` function. You can use this function to reduce the amount of time it takes to find a host to connect to. However, in certain network failure scenarios the `aurora_replica_status` function might show out-of-date or incomplete information.

A good way to ensure that your application can find a node to connect to is to try to connect to the cluster writer endpoint and then the cluster reader endpoint. You do this until you can establish a readable connection. These endpoints don't change unless you rename your DB cluster. Thus, you can generally leave them as static members of your application or store them in a resource file that your application reads from.

After you establish a connection using one of these endpoints, you can get information about the rest of the cluster. To do this, call the `aurora_replica_status` function. For example, the following command retrieves information with `aurora_replica_status`.

```
postgres=> SELECT server_id, session_id, highest_lsn_rcvd, cur_replay_latency_in_usec,
    now(), last_update_timestamp
  FROM aurora_replica_status();

server_id | session_id | highest_lsn_rcvd | cur_replay_latency_in_usec | now | last_update_timestamp
-----+-----+-----+-----+-----+-----+
mynode-1 | 3e3c5044-02e2-11e7-b70d-95172646d6ca | 594221001 | 201421 | 2017-03-07
19:50:24.695322+00 | 2017-03-07 19:50:23+00
mynode-2 | 1efdd188-02e4-11e7-becd-f12d7c88a28a | 594221001 | 201350 | 2017-03-07
19:50:24.695322+00 | 2017-03-07 19:50:23+00
mynode-3 | MASTER_SESSION_ID | | 2017-03-07 19:50:24.695322+00 | 2017-03-07 19:50:23+00
(3 rows)
```

For example, the hosts section of your connection string might start with both the writer and reader cluster endpoints, as shown following.

```
myauroracluster.cluster-c9bfei4hj1rd.us-east-1-beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hj1rd.us-east-1-beta.rds.amazonaws.com:5432
```

In this scenario, your application attempts to establish a connection to any node type, primary or secondary. When your application is connected, a good practice is to first examine the read/write status of the node. To do this, query for the result of the command `SHOW transaction_read_only`.

If the return value of the query is `OFF`, then you successfully connected to the primary node. However, suppose that the return value is `ON` and your application requires a read/write connection. In this case, you can call the `aurora_replica_status` function to determine the `server_id` that has `session_id='MASTER_SESSION_ID'`. This function gives you the name of the primary node. You can use this with the `endpointPostfix` described following.

Make sure that you're aware when you connect to a replica that has stale data. When this happens, the `aurora_replica_status` function might show out-of-date information. You can set a threshold for staleness at the application level. To check this, you can look at the difference between the server time and the `last_update_timestamp` value. In general, your application should avoid flipping between two hosts due to conflicting information returned by the `aurora_replica_status` function. Your application should try all known hosts first instead of following the data returned by `aurora_replica_status`.

### [Listing instances using the `DescribeDBClusters` API operation, example in Java](#)

You can programmatically find the list of instances by using the [AWS SDK for Java](#), specifically the `DescribeDBClusters` API operation.

Following is a small example of how you might do this in Java 8.

```
AmazonRDS client = AmazonRDSClientBuilder.defaultClient();
DescribeDBClustersRequest request = new DescribeDBClustersRequest()
    .withDBClusterIdentifier(clusterName);
DescribeDBClustersResult result =
rdsClient.describeDBClusters(request);

DBCluster singleClusterResult = result.getDBClusters().get(0);

String pgJDBCEndpointStr =
singleClusterResult.getDBClusterMembers().stream()
    .sorted(Comparator.comparing(DBClusterMember::getIsClusterWriter)
    .reversed()) // This puts the writer at the front of the list
    .map(m -> m.getDBInstanceIdentifier() + endpointPostfix + ":" +
singleClusterResult.getPort())
    .collect(Collectors.joining(","));
```

Here, `pgJDBCEndpointStr` contains a formatted list of endpoints, as shown following.

```
my-node1.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node2.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432
```

The variable `endpointPostfix` can be a constant that your application sets. Or your application can get it by querying the `DescribeDBInstances` API operation for a single instance in your cluster. This value remains constant within an AWS Region and for an individual customer. So it saves an API call to simply keep this constant in a resource file that your application reads from. In the example preceding, it's set to the following.

```
.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com
```

For availability purposes, a good practice is to default to using the Aurora endpoints of your DB cluster if the API isn't responding or takes too long to respond. The endpoints are guaranteed to be up to date within the time it takes to update the DNS record. Updating the DNS record with an endpoint typically takes less than 30 seconds. You can store the endpoint in a resource file that your application consumes.

## Testing failover

In all cases you must have a DB cluster with two or more DB instances in it.

From the server side, certain API operations can cause an outage that can be used to test how your applications responds:

- [`FailoverDBCluster`](#) – This operation attempts to promote a new DB instance in your DB cluster to writer.

The following code example shows how you can use `failoverDBCluster` to cause an outage. For more details about setting up an Amazon RDS client, see [Using the AWS SDK for Java](#).

```

public void causeFailover() {

    final AmazonRDS rdsClient = AmazonRDSClientBuilder.defaultClient();

    FailoverDBClusterRequest request = new FailoverDBClusterRequest();
    request.setDBClusterIdentifier("cluster-identifier");

    rdsClient.failoverDBCluster(request);
}

```

- [RebootDBInstance](#) – Failover isn't guaranteed with this API operation. It shuts down the database on the writer, however. You can use it to test how your application responds to connections dropping. The `ForceFailover` parameter doesn't apply for Aurora engines. Instead, use the `FailoverDBCluster` API operation.
- [ModifyDBCluster](#) – Modifying the `Port` parameter causes an outage when the nodes in the cluster begin listening on a new port. In general, your application can respond to this failure first by ensuring that only your application controls port changes. Also, ensure that it can appropriately update the endpoints it depends on. You can do this by having someone manually update the port when they make modifications at the API level. Or you can do this by using the RDS API in your application to determine if the port has changed.
- [ModifyDBInstance](#) – Modifying the `DBInstanceClass` parameter causes an outage.
- [DeleteDBInstance](#) – Deleting the primary (writer) causes a new DB instance to be promoted to writer in your DB cluster.

From the application or client side, if you use Linux, you can test how the application responds to sudden packet drops. You can do this based on whether port, host, or if TCP keepalive packets are sent or received by using the `iptables` command.

## Fast failover example in Java

The following code example shows how an application might set up an Aurora PostgreSQL driver manager.

The application calls the `getConnection` function when it needs a connection. A call to `getConnection` can fail to find a valid host. An example is when no writer is found but the `targetServerType` parameter is set to `primary`. In this case, the calling application should simply retry calling the function.

To avoid pushing the retry behavior onto the application, you can wrap this retry call into a connection pooler. With most connection poolers, you can specify a JDBC connection string. So your application can call into `getJdbcConnectionString` and pass that to the connection pooler. Doing this means you can use faster failover with Aurora PostgreSQL.

```

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.sql.Statement;
import java.util.ArrayList;
import java.util.List;
import java.util.stream.Collectors;
import java.util.stream.IntStream;

import org.joda.time.Duration;

public class FastFailoverDriverManager {
    private static Duration LOGIN_TIMEOUT = Duration.standardSeconds(2);
    private static Duration CONNECT_TIMEOUT = Duration.standardSeconds(2);
    private static Duration CANCEL_SIGNAL_TIMEOUT = Duration.standardSeconds(1);
}

```

```

private static Duration DEFAULT_SOCKET_TIMEOUT = Duration.standardSeconds(5);

public FastFailoverDriverManager() {
    try {
        Class.forName("org.postgresql.Driver");
    } catch (ClassNotFoundException e) {
        e.printStackTrace();
    }

    /*
     * RO endpoint has a TTL of 1s, we should honor that here. Setting this
     aggressively makes sure that when
     * the PG JDBC driver creates a new connection, it will resolve a new different RO
     endpoint on subsequent attempts
     * (assuming there is > 1 read node in your cluster)
     */
    java.security.Security.setProperty("networkaddress.cache.ttl" , "1");
    // If the lookup fails, default to something like small to retry
    java.security.Security.setProperty("networkaddress.cache.negative.ttl" , "3");
}

public Connection getConnection(String targetServerType) throws SQLException {
    return getConnection(targetServerType, DEFAULT_SOCKET_TIMEOUT);
}

public Connection getConnection(String targetServerType, Duration queryTimeout) throws
SQLException {
    Connection conn =
DriverManager.getConnection(getJdbcConnectionString(targetServerType, queryTimeout));

    /*
     * A good practice is to set socket and statement timeout to be the same thing
     since both
     * the client AND server will stop the query at the same time, leaving no running
     queries
     * on the backend
     */
    Statement st = conn.createStatement();
    st.execute("set statement_timeout to " + queryTimeout.getMillis());
    st.close();

    return conn;
}

private static String urlFormat = "jdbc:postgresql:///%s"
    + "/postgres"
    + "?user=%s"
    + "&password=%s"
    + "&loginTimeout=%d"
    + "&connectTimeout=%d"
    + "&cancelSignalTimeout=%d"
    + "&socketTimeout=%d"
    + "&targetServerType=%s"
    + "&tcpKeepAlive=true"
    + "&ssl=true"
    + "&loadBalanceHosts=true";
public String getJdbcConnectionString(String targetServerType, Duration queryTimeout) {
    return String.format(urlFormat,
        getFormattedEndpointList(getLocalEndpointList()),
        CredentialManager.getUsername(),
        CredentialManager.getPassword(),
        LOGIN_TIMEOUT.getStandardSeconds(),
        CONNECT_TIMEOUT.getStandardSeconds(),
        CANCEL_SIGNAL_TIMEOUT.getStandardSeconds(),
        queryTimeout.getStandardSeconds(),
        targetServerType
}

```

```
        );
    }

    private List<String> getLocalEndpointList() {
        /*
         * As mentioned in the best practices doc, a good idea is to read a local resource
         * file and parse the cluster endpoints.
         * For illustration purposes, the endpoint list is hardcoded here
         */
        List<String> newEndpointList = new ArrayList<>();
        newEndpointList.add("myauroracluster.cluster-c9bfei4hj1rd.us-east-1-
beta.rds.amazonaws.com:5432");
        newEndpointList.add("myauroracluster.cluster-ro-c9bfei4hj1rd.us-east-1-
beta.rds.amazonaws.com:5432");

        return newEndpointList;
    }

    private static String getFormattedEndpointList(List<String> endpoints) {
        return IntStream.range(0, endpoints.size())
            .mapToObj(i -> endpoints.get(i).toString())
            .collect(Collectors.joining(","));
    }
}
```

## Fast recovery after failover with cluster cache management for Aurora PostgreSQL

For fast recovery of the writer DB instance in your Aurora PostgreSQL clusters if there's a failover, use cluster cache management for Amazon Aurora PostgreSQL. Cluster cache management ensures that application performance is maintained if there's a failover.

In a typical failover situation, you might see a temporary but large performance degradation after failover. This degradation occurs because when the failover DB instance starts, the buffer cache is empty. An empty cache is also known as a *cold cache*. A cold cache degrades performance because the DB instance has to read from the slower disk, instead of taking advantage of values stored in the buffer cache.

With cluster cache management, you set a specific reader DB instance as the failover target. Cluster cache management ensures that the data in the designated reader's cache is kept synchronized with the data in the writer DB instance's cache. The designated reader's cache with prefilled values is known as a *warm cache*. If a failover occurs, the designated reader uses values in its warm cache immediately when it's promoted to the new writer DB instance. This approach provides your application much better recovery performance.

Cluster cache management requires that the designated reader instance have the same instance class type and size (db.r5.2xlarge or db.r5.xlarge, for example) as the writer. Keep this in mind when you create your Aurora PostgreSQL DB clusters so that your cluster can recover during a failover. For a listing of instance class types and sizes, see [Hardware specifications for DB instance classes for Aurora](#).

### Note

Cluster cache management is not supported for Aurora PostgreSQL DB clusters that are part of Aurora global databases.

### Contents

- [Configuring cluster cache management \(p. 1209\)](#)
  - [Enabling cluster cache management \(p. 1209\)](#)
  - [Setting the promotion tier priority for the writer DB instance \(p. 1210\)](#)
  - [Setting the promotion tier priority for a reader DB instance \(p. 1210\)](#)

- Monitoring the buffer cache (p. 1211)

## Configuring cluster cache management

To configure cluster cache management, do the following processes in order.

### Topics

- Enabling cluster cache management (p. 1209)
- Setting the promotion tier priority for the writer DB instance (p. 1210)
- Setting the promotion tier priority for a reader DB instance (p. 1210)

### Note

Allow at least 1 minute after completing these steps for cluster cache management to be fully operational.

## Enabling cluster cache management

To enable cluster cache management, take the steps described following.

### Console

#### To enable cluster cache management

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group for your Aurora PostgreSQL DB cluster.

The DB cluster must use a parameter group other than the default, because you can't change values in a default parameter group.

4. For **Parameter group actions**, choose **Edit**.
5. Set the value of the `apg_ccm_enabled` cluster parameter to **1**.
6. Choose **Save changes**.

### AWS CLI

To enable cluster cache management for an Aurora PostgreSQL DB cluster, use the AWS CLI `modify-db-cluster-parameter-group` command with the following required parameters:

- `--db-cluster-parameter-group-name`
- `--parameters`

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
--db-cluster-parameter-group-name my-db-cluster-parameter-group \
--parameters "ParameterName=apg_ccm_enabled,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
--db-cluster-parameter-group-name my-db-cluster-parameter-group ^
```

```
--parameters "ParameterName=apg_ccm_enabled,ParameterValue=1,ApplyMethod=immediate"
```

## Setting the promotion tier priority for the writer DB instance

For cluster cache management, make sure that the promotion priority is **tier-0** for the writer DB instance of the Aurora PostgreSQL DB cluster. The *promotion tier priority* is a value that specifies the order in which an Aurora reader is promoted to the writer DB instance after a failure. Valid values are 0–15, where 0 is the first priority and 15 is the last priority. For more information about the promotion tier, see [Fault tolerance for an Aurora DB cluster \(p. 72\)](#).

### Console

#### To set the promotion priority for the writer DB instance to tier-0

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the **Writer** DB instance of the Aurora PostgreSQL DB cluster.
4. Choose **Modify**. The **Modify DB Instance** page appears.
5. On the **Additional configuration** panel, choose **tier-0** for the **Failover priority**.
6. Choose **Continue** and check the summary of modifications.
7. To apply the changes immediately after you save them, choose **Apply immediately**.
8. Choose **Modify DB Instance** to save your changes.

### AWS CLI

To set the promotion tier priority to 0 for the writer DB instance using the AWS CLI, call the `modify-db-instance` command with the following required parameters:

- `--db-instance-identifier`
- `--promotion-tier`
- `--apply-immediately`

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier writer-db-instance \
--promotion-tier 0 \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier writer-db-instance ^
--promotion-tier 0 ^
--apply-immediately
```

## Setting the promotion tier priority for a reader DB instance

You set one reader DB instance for cluster cache management. To do so, choose a reader from the Aurora PostgreSQL cluster that is the same instance class and size as the writer DB instance. For example, if the

writer uses db.r5.xlarge, choose a reader that uses this same instance class type and size. Then set its promotion tier priority to 0.

The *promotion tier priority* is a value that specifies the order in which an Aurora reader is promoted to the writer DB instance after a failure. Valid values are 0–15, where 0 is the first priority and 15 is the last priority.

## Console

### To set the promotion priority of the reader DB instance to tier-0

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose a **Reader** DB instance of the Aurora PostgreSQL DB cluster that is the same instance class as the writer DB instance.
4. Choose **Modify**. The **Modify DB Instance** page appears.
5. On the **Additional configuration** panel, choose **tier-0** for the **Failover priority**.
6. Choose **Continue** and check the summary of modifications.
7. To apply the changes immediately after you save them, choose **Apply immediately**.
8. Choose **Modify DB Instance** to save your changes.

## AWS CLI

To set the promotion tier priority to 0 for the reader DB instance using the AWS CLI, call the `modify-db-instance` command with the following required parameters:

- `--db-instance-identifier`
- `--promotion-tier`
- `--apply-immediately`

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier reader-db-instance \
  --promotion-tier 0 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier reader-db-instance ^
  --promotion-tier 0 ^
  --apply-immediately
```

## Monitoring the buffer cache

After setting up cluster cache management, you can monitor the state of synchronization between the writer DB instance's buffer cache and the designated reader's warm buffer cache. To examine the buffer cache contents on both the writer DB instance and the designated reader DB instance, use the

PostgreSQL pg\_buffercache module. For more information, see the [PostgreSQL pg\\_buffercache documentation](#).

#### Using the aurora\_ccm\_status Function

Cluster cache management also provides the aurora\_ccm\_status function. Use the aurora\_ccm\_status function on the writer DB instance to get the following information about the progress of cache warming on the designated reader:

- buffers\_sent\_last\_minute – How many buffers have been sent to the designated reader in the last minute.
- buffers\_sent\_last\_scan – How many buffers have been sent to the designated reader during the last complete scan of the buffer cache.
- buffers\_found\_last\_scan – How many buffers have been identified as frequently accessed and needed to be sent during the last complete scan of the buffer cache. Buffers already cached on the designated reader aren't sent.
- buffers\_sent\_current\_scan – How many buffers have been sent so far during the current scan.
- buffers\_found\_current\_scan – How many buffers have been identified as frequently accessed in the current scan.
- current\_scan\_progress – How many buffers have been visited so far during the current scan.

The following example shows how to use the aurora\_ccm\_status function to convert some of its output into a warm rate and warm percentage.

```
SELECT buffers_sent_last_minute*8/60 AS warm_rate_kbps,
       100*(1.0-buffers_sent_last_scan/buffers_found_last_scan) AS warm_percent
  FROM aurora_ccm_status();
```

## Managing Aurora PostgreSQL connection churn with pooling

When client applications connect and disconnect so often that Aurora PostgreSQL DB cluster response time slows, the cluster is said to be experiencing *connection churn*. Each new connection to the Aurora PostgreSQL DB cluster endpoint consumes resources, thus reducing the resources that can be used to process the actual workload. Connection churn is an issue that we recommend that you manage by following some of the best practices discussed following.

For starters, you can improve response times on Aurora PostgreSQL DB clusters that have high rates of connection churn. To do this, you can use a connection pooler, such as RDS Proxy. A *connection pooler* provides a cache of ready to use connections for clients. Almost all versions of Aurora PostgreSQL support RDS Proxy. For more information, see [Amazon RDS Proxy with Aurora PostgreSQL \(p. 29\)](#).

If your specific version of Aurora PostgreSQL doesn't support RDS Proxy, you can use another PostgreSQL-compatible connection pooler, such as PgBouncer. To learn more, see the [PgBouncer website](#).

To see if your Aurora PostgreSQL DB cluster can benefit from connection pooling, you can check the postgresql.log file for connections and disconnections. You can also use Performance Insights to find out how much connection churn your Aurora PostgreSQL DB cluster is experiencing. Following, you can find information about both topics.

## Logging connections and disconnections

The PostgreSQL log\_connections and log\_disconnections parameters can capture connections and disconnections to the writer instance of the Aurora PostgreSQL DB cluster. By default, these

parameters are turned off. To turn these parameters on, use a custom parameter group and turn on by changing the value to 1. For more information about custom parameter groups, see [Working with DB cluster parameter groups \(p. 217\)](#). To check the settings, connect to your DB cluster endpoint for Aurora PostgreSQL by using psql and query as follows.

```
labdb=> SELECT setting FROM pg_settings
  WHERE name = 'log_connections';
setting
-----
on
(1 row)
labdb=> SELECT setting FROM pg_settings
  WHERE name = 'log_disconnections';
setting
-----
on
(1 row)
```

With both of these parameters turned on, the log captures all new connections and disconnections. You see the user and database for each new authorized connection. At disconnection time, the session duration is also logged, as shown in the following example.

```
2022-03-07 21:44:53.978 UTC [16641] LOG: connection authorized: user=labtek database=labdb
application_name=psql
2022-03-07 21:44:55.718 UTC [16641] LOG: disconnection: session time: 0:00:01.740
user=labtek database=labdb host=[local]
```

To check your application for connection churn, turn on these parameters if they're not on already. Then gather data in the PostgreSQL log for analysis by running your application with a realistic workload and time period. You can view the log file in the RDS console. Choose the writer instance of your Aurora PostgreSQL DB cluster, and then choose the **Logs & events** tab. For more information, see [Viewing and listing database log files \(p. 597\)](#).

Or you can download the log file from the console and use the following command sequence. This sequence finds the total number of connections authorized and dropped per minute.

```
grep "connection authorized\|disconnection: session time:" postgresql.log.2022-03-21-16 | \
awk '{print $1,$2}' | \
sort | \
uniq -c | \
sort -n -k1
```

In the example output, you can see a spike in authorized connections followed by disconnections starting at 16:12:10.

```
.....
.....
.....
5 2022-03-21 16:11:55 connection authorized:
9 2022-03-21 16:11:55 disconnection: session
5 2022-03-21 16:11:56 connection authorized:
5 2022-03-21 16:11:57 connection authorized:
5 2022-03-21 16:11:57 disconnection: session
32 2022-03-21 16:12:10 connection authorized:
30 2022-03-21 16:12:10 disconnection: session
31 2022-03-21 16:12:11 connection authorized:
27 2022-03-21 16:12:11 disconnection: session
27 2022-03-21 16:12:12 connection authorized:
27 2022-03-21 16:12:12 disconnection: session
41 2022-03-21 16:12:13 connection authorized:
47 2022-03-21 16:12:13 disconnection: session
```

```

46 2022-03-21 16:12:14 connection authorized:
41 2022-03-21 16:12:14 disconnection: session
24 2022-03-21 16:12:15 connection authorized:
29 2022-03-21 16:12:15 disconnection: session
28 2022-03-21 16:12:16 connection authorized:
24 2022-03-21 16:12:16 disconnection: session
40 2022-03-21 16:12:17 connection authorized:
42 2022-03-21 16:12:17 disconnection: session
40 2022-03-21 16:12:18 connection authorized:
40 2022-03-21 16:12:18 disconnection: session
.....
.....
.....
1 2022-03-21 16:14:10 connection authorized:
1 2022-03-21 16:14:10 disconnection: session
1 2022-03-21 16:15:00 connection authorized:
1 2022-03-21 16:16:00 connection authorized:

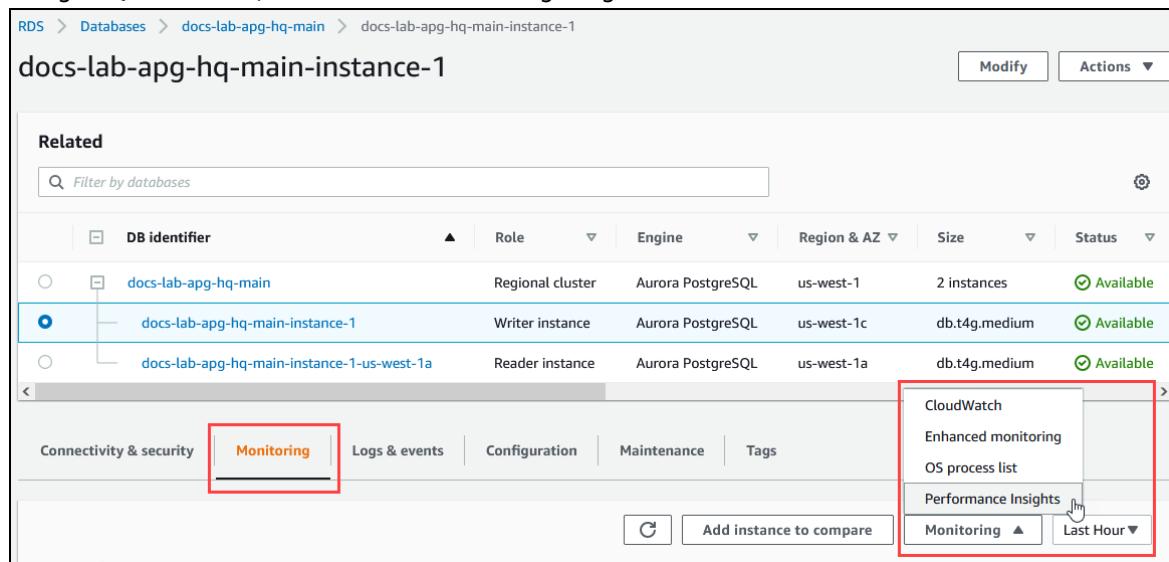

```

With this information, you can decide if your workload can benefit from a connection pooler. For more detailed analysis, you can use Performance Insights.

## Detecting connection churn with Performance Insights

You can use Performance Insights to assess the amount of connection churn on your Aurora PostgreSQL-Compatible Edition DB cluster. When you create an Aurora PostgreSQL DB cluster, the setting for Performance Insights is turned on by default. If you cleared this choice when you created your DB cluster, modify your cluster to turn on the feature. For more information, see [Modifying an Amazon Aurora DB cluster \(p. 248\)](#).

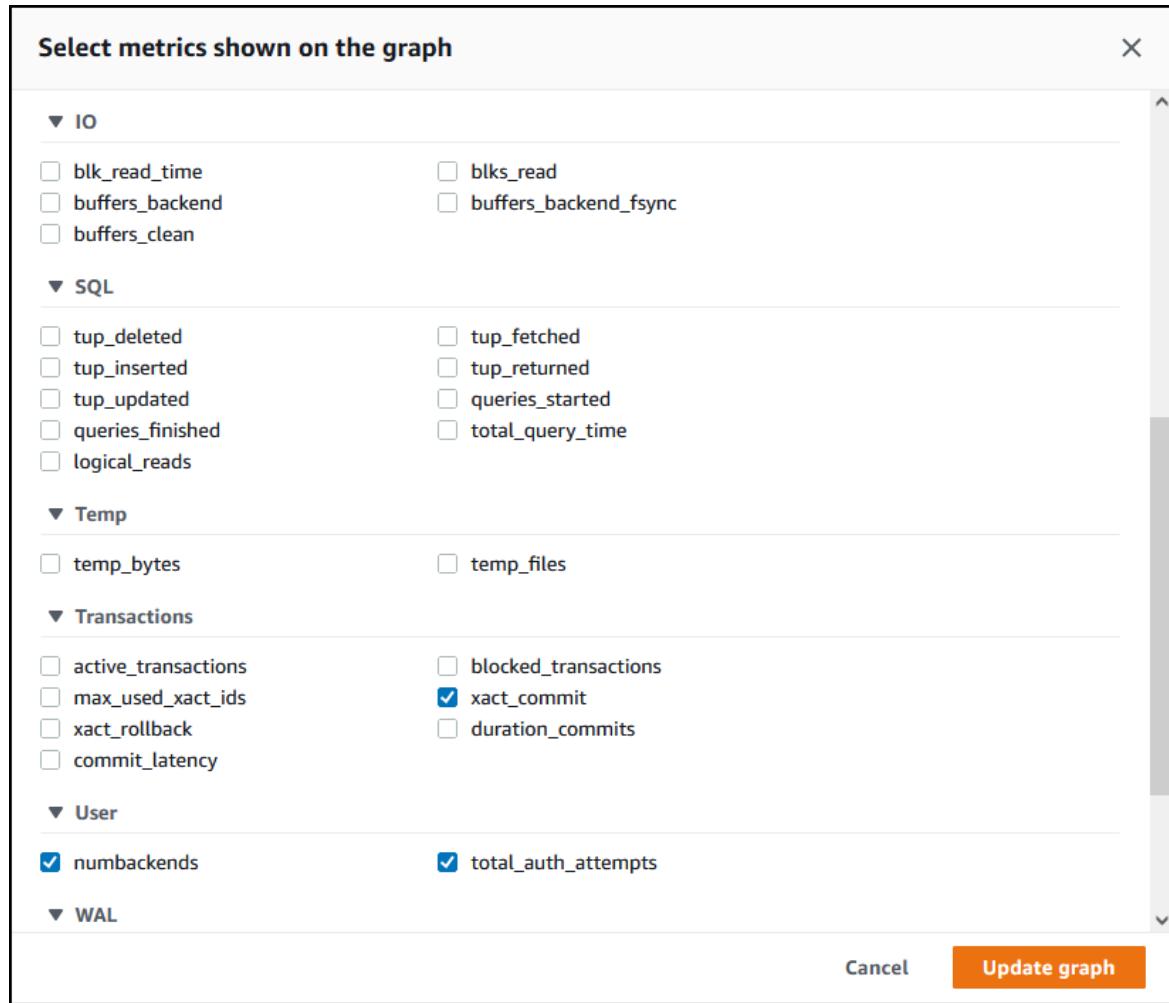

With Performance Insights running on your Aurora PostgreSQL DB cluster, you can choose the metrics that you want to monitor. You can access Performance Insights from the navigation pane in the console. You can also access Performance Insights from the **Monitoring** tab of the writer instance for your Aurora PostgreSQL DB cluster, as shown in the following image.

From the Performance Insights console, choose **Manage metrics**. To analyze your Aurora PostgreSQL DB cluster's connection and disconnection activity, choose the following metrics. These are all metrics from PostgreSQL.

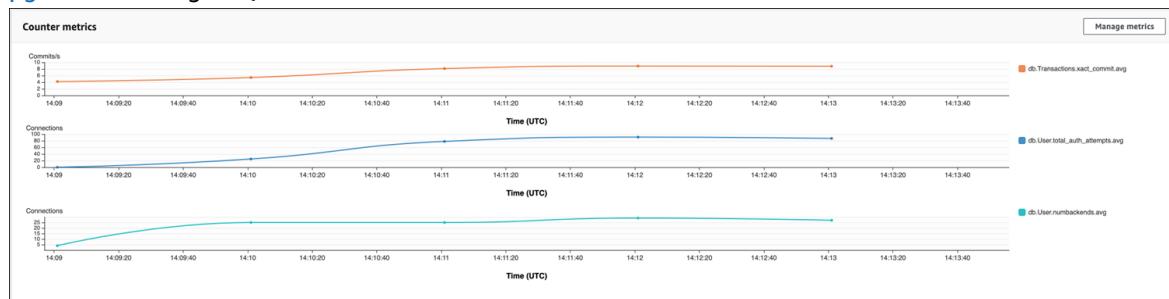

- **xact\_commit** – The number of committed transactions.
- **total\_auth\_attempts** – The number of attempted authenticated user connections.

- numbackends – The number of backends currently connected to the database.

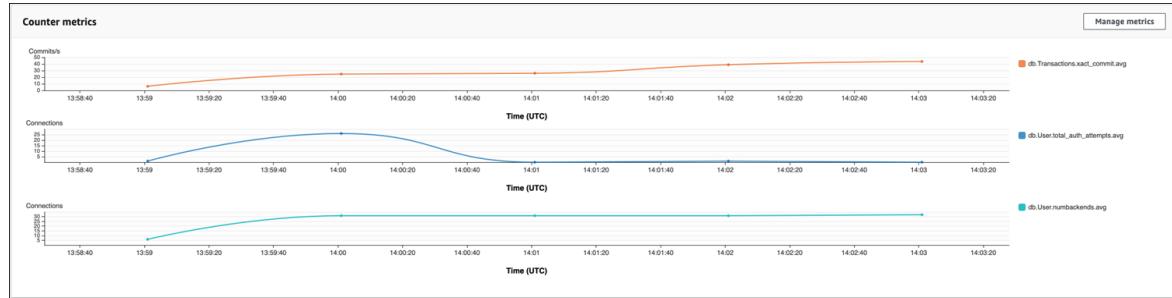

To save the settings and display connection activity, choose **Update graph**.

In the following image, you can see the impact of running pgbench with 100 users. The line showing connections is on a consistent upward slope. To learn more about pgbench and how to use it, see [pgbench](#) in PostgreSQL documentation.

The image shows that running a workload with as few as 100 users without a connection pooler can cause a significant increase in the number of `total_auth_attempts` throughout the duration of workload processing.

With RDS Proxy connection pooling, the connection attempts increase at the start of the workload. After setting up the connection pool, the average declines. The resources used by transactions and backend use stays consistent throughout workload processing.

For more information about using Performance Insights with your Aurora PostgreSQL DB cluster, see [Monitoring DB load with Performance Insights on Amazon Aurora \(p. 461\)](#). To analyze the metrics, see [Analyzing metrics with the Performance Insights dashboard \(p. 476\)](#).

## Demonstrating the benefits of connection pooling

As mentioned previously, if you determine that your Aurora PostgreSQL DB cluster has a connection churn problem, you can use RDS Proxy for improved performance. Following, you can find an example that shows the differences in processing a workload when connections are pooled and when they're not. The example uses pgbench to model a transaction workload.

As is psql, pgbench is a PostgreSQL client application that you can install and run from your local client machine. You can also install and run it from the Amazon EC2 instance that you use for managing your Aurora PostgreSQL DB cluster. For more information, see [pgbench](#) in the PostgreSQL documentation.

To step through this example, you first create the pgbench environment in your database. The following command is the basic template for initializing the pgbench tables in the specified database. This example uses the default main user account, `postgres`, for the login. Change it as needed for your Aurora PostgreSQL DB cluster. You create the pgbench environment in a database on the writer instance of your cluster.

### Note

The pgbench initialization process drops and recreates tables named `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`. Be sure that the database that you choose for `dbname` when you initialize pgbench doesn't use these names.

```
pgbench -U postgres -h db-cluster-instance-1.111122223333.aws-region.rds.amazonaws.com -p 5432 -d -i -s 50 dbname
```

For pgbench, specify the following parameters.

**-d**

Outputs a debugging report as pgbench runs.

**-h**

Specifies the endpoint of the Aurora PostgreSQL DB cluster's writer instance.

**-i**

Initializes the pgbench environment in the database for the benchmark tests.

**-p**

Identifies the port used for database connections. The default for Aurora PostgreSQL is typically 5432 or 5433.

**-s**

Specifies the scaling factor to use for populating the tables with rows. The default scaling factor is 1, which generates 1 row in the pgbench\_branches table, 10 rows in the pgbench\_tellers table, and 100000 rows in the pgbench\_accounts table.

**-U**

Specifies the user account for the Aurora PostgreSQL DB cluster's writer instance.

After the pgbench environment is set up, you can then run benchmarking tests with and without connection pooling. The default test consists of a series of five SELECT, UPDATE, and INSERT commands per transaction that run repeatedly for the time specified. You can specify scaling factor, number of clients, and other details to model your own use cases.

As an example, the command that follows runs the benchmark for 60 seconds (-T option, for time) with 20 concurrent connections (the -c option). The -C option makes the test run using a new connection each time, rather than once per client session. This setting gives you an indication of the connection overhead.

```
pgbench -h docs-lab-apg-133-test-instance-1.c3zr2auzukpa.us-west-1.rds.amazonaws.com -U
postgres -p 5432 -T 60 -c 20 -C labdb
Password:*****
pgbench (14.3, server 13.3)
      starting vacuum...end.
      transaction type: <builtin: TPC-B (sort of)>
      scaling factor: 50
      query mode: simple
      number of clients: 20
      number of threads: 1
      duration: 60 s
      number of transactions actually processed: 495
      latency average = 2430.798 ms
      average connection time = 120.330 ms
      tps = 8.227750 (including reconnection times)
```

Running pgbench on the writer instance of an Aurora PostgreSQL DB cluster without reusing connections shows that only about 8 transactions are processed each second. This gives a total of 495 transactions during the 1-minute test.

If you reuse connections, the response from Aurora PostgreSQL DB cluster for the number of users is almost 20 times faster. With reuse, a total of 9,042 transactions is processed compared to 495 in the same amount of time and for the same number of user connections. The difference is that in the following, each connection is being reused.

```
pgbench -h docs-lab-apg-133-test-instance-1.c3zr2auzukpa.us-west-1.rds.amazonaws.com -U
postgres -p 5432 -T 60 -c 20 labdb
Password:*****
pgbench (14.3, server 13.3)
      starting vacuum...end.
      transaction type: <builtin: TPC-B (sort of)>
      scaling factor: 50
      query mode: simple
      number of clients: 20
      number of threads: 1
      duration: 60 s
      number of transactions actually processed: 9042
      latency average = 127.880 ms
      initial connection time = 2311.188 ms
      tps = 156.396765 (without initial connection time)
```

This example shows you that pooling connections can significantly improve response times. For information about setting up RDS Proxy for your Aurora PostgreSQL DB cluster, see [Using Amazon RDS Proxy \(p. 1430\)](#).

## Tuning memory parameters for Aurora PostgreSQL

In Amazon Aurora PostgreSQL, you can use several parameters that control the amount of memory used for various processing tasks. If a task takes more memory than the amount set for a given parameter, Aurora PostgreSQL uses other resources for processing, such as by writing to disk. This can cause your Aurora PostgreSQL DB cluster to slow or potentially halt, with an out-of-memory error.

The default setting for each memory parameter can usually handle its intended processing tasks. However, you can also tune your Aurora PostgreSQL DB cluster's memory-related parameters. You do this tuning to ensure that enough memory is allocated for processing your specific workload.

Following, you can find information about parameters that control memory management. You can also learn how to assess memory utilization.

### Checking and setting parameter values

The parameters that you can set to manage memory and assess your Aurora PostgreSQL DB cluster's memory usage include the following:

- `work_mem` – Specifies the amount of memory that the Aurora PostgreSQL DB cluster uses for internal sort operations and hash tables before it writes to temporary disk files.
- `log_temp_files` – Logs temporary file creation, file names, and sizes. When this parameter is turned on, a log entry is stored for each temporary file that gets created. Turn this on to see how frequently your Aurora PostgreSQL DB cluster needs to write to disk. Turn it off again after you've gathered information about your Aurora PostgreSQL DB cluster's temporary file generation, to avoid excessive logging.
- `logical_decoding_work_mem` – Specifies the amount of memory (in megabytes) to use for logical decoding. *Logical decoding* is the process used to create a replica. This process is done by converting data from the write-ahead log (WAL) file to the logical streaming output needed by the target.

The value of this parameter creates a single buffer of the size specified for each replication connection. By default, it's 64 megabytes. After this buffer is filled, the excess is written to disk as a file. To minimize disk activity, you can set the value of this parameter to a much higher value than that of `work_mem`.

These are all dynamic parameters, so you can change them for the current session. To do this, connect to the Aurora PostgreSQL DB cluster with `psql` and using the `SET` statement, as shown following.

```
SET parameter_name TO parameter_value;
```

Session settings last for the duration of the session only. When the session ends, the parameter reverts to its setting in the DB cluster parameter group. Before changing any parameters, first check the current values by querying the `pg_settings` table, as follows.

```
SELECT unit, setting, max_val
  FROM pg_settings WHERE name='parameter_name';
```

For example, to find the value of the `work_mem` parameter, connect to the Aurora PostgreSQL DB cluster's writer instance and run the following query.

```
SELECT unit, setting, max_val, pg_size.pretty(max_val::numeric)
  FROM pg_settings WHERE name='work_mem';
unit | setting | max_val | pg_size.pretty
-----+-----+-----+
kB   | 1024   | 2147483647| 2048 MB
(1 row)
```

Changing parameter settings so that they persist requires using a custom DB cluster parameter group. After exercising your Aurora PostgreSQL DB cluster with different values for these parameters using the `SET` statement, you can create a custom parameter group and apply to your Aurora PostgreSQL DB cluster. For more information, see [Working with parameter groups \(p. 215\)](#).

## Understanding the working memory parameter

The working memory parameter (`work_mem`) specifies the maximum amount of memory that Aurora PostgreSQL can use to process complex queries. Complex queries include those that involve sorting or grouping operations—in other words, queries that use the following clauses:

- ORDER BY
- DISTINCT
- GROUP BY
- JOIN (MERGE and HASH)

The query planner indirectly affects how your Aurora PostgreSQL DB cluster uses working memory. The query planner generates execution plans for processing SQL statements. A given plan might break up a complex query into multiple units of work that can be run in parallel. When possible, Aurora PostgreSQL uses the amount of memory specified in the `work_mem` parameter for each session before writing to disk for each parallel process.

Multiple database users running multiple operations concurrently and generating multiple units of work in parallel can exhaust your Aurora PostgreSQL DB cluster's allocated working memory. This can lead to excessive temporary file creation and disk I/O, or worse, it can lead to an out-of-memory error.

## Identifying temporary file use

Whenever the memory required to process queries exceeds the value specified in the `work_mem` parameter, the working data is offloaded to disk in a temporary file. You can see how often this occurs by turning on the `log_temp_files` parameter. By default, this parameter is off (it's set to -1). To capture all temporary file information, set this parameter to 0. Set `log_temp_files` to any other positive integer to capture temporary file information for files equal to or greater than that amount of data (in kilobytes). In the following image, you can see an example from AWS Management Console.

	Name	Values	Allowed values	Modifiable	Source
	log_temp_files	1024	-1-2147483647	true	user

After configuring temporary file logging, you can test with your own workload to see if your working memory setting is sufficient. You can also simulate a workload by using pgbench, a simple benchmarking application from the PostgreSQL community.

The following example initializes (-i) pgbench by creating the necessary tables and rows for running the tests. In this example, the scaling factor (-s 50) creates 50 rows in the pgbench\_branches table, 500 rows in pgbench\_tellers, and 5,000,000 rows in the pgbench\_accounts table in the labdb database.

```
pgbench -U postgres -h your-cluster-instance-1.111122223333.aws-regionrds.amazonaws.com -p 5432 -i -s 50 labdb
Password:
dropping old tables...
NOTICE: table "pgbench_accounts" does not exist, skipping
NOTICE: table "pgbench_branches" does not exist, skipping
NOTICE: table "pgbench_history" does not exist, skipping
NOTICE: table "pgbench_tellers" does not exist, skipping
creating tables...
generating data (client-side)...
5000000 of 5000000 tuples (100%) done (elapsed 15.46 s, remaining 0.00 s)
vacuuming...
creating primary keys...
done in 61.13 s (drop tables 0.08 s, create tables 0.39 s, client-side generate 54.85 s,
vacuum 2.30 s, primary keys 3.51 s)
```

After initializing the environment, you can run the benchmark for a specific time (-T) and the number of clients (-c). This example also uses the -d option to output debugging information as the transactions are processed by the Aurora PostgreSQL DB cluster.

```
pgbench -h -U postgres your-cluster-instance-1.111122223333.aws-regionrds.amazonaws.com -p 5432 -d -T 60 -c 10 labdb
Password:*****
pgbench (14.3)
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 50
query mode: simple
number of clients: 10
number of threads: 1
duration: 60 s
```

```
number of transactions actually processed: 1408
latency average = 398.467 ms
initial connection time = 4280.846 ms
tps = 25.096201 (without initial connection time)
```

For more information about pgbench, see [pgbench](#) in the PostgreSQL documentation.

You can use the psql metacommand command (\d) to list the relations such as tables, views, and indexes created by pgbench.

```
labdb=> \d pgbench_accounts
Table "public.pgbench_accounts"
 Column | Type | Collation | Nullable | Default
-----+-----+-----+-----+-----+
 aid | integer | | not null |
 bid | integer | | |
 abalance | integer | | |
 filler | character(84) | | |
Indexes:
"pgbench_accounts_pkey" PRIMARY KEY, btree (aid)
```

As shown in the output, the pgbench\_accounts table is indexed on the aid column. To ensure that this next query uses working memory, query any nonindexed column, such as that shown in the following example.

```
postgres=> SELECT * FROM pgbench_accounts ORDER BY bid;
```

Check the log for the temporary files. To do so, open the AWS Management Console, choose the Aurora PostgreSQL DB cluster instance, and then choose the **Logs & Events** tab. View the logs in the console or download for further analysis. As shown in the following image, the size of the temporary files needed to process the query indicates that you should consider increasing the amount specified for the `work_mem` parameter.

```
2022-07-07 23:00:02 UTC:[local]:[unknown]@[unknown]:[9698]:LOG: connection received: host=[local]
2022-07-07 23:02:02 UTC:[local]:[unknown]@[unknown]:[15780]:LOG: connection received: host=[local]
2022-07-07 23:04:02 UTC:[local]:[unknown]@[unknown]:[21216]:LOG: connection received: host=[local]
2022-07-07 23:04:16 UTC:@:[18585]:LOG: temporary file: path "base/pgsql_tmp/pgsql_tmp18585.0", size
2022-07-07 23:04:16 UTC:@:[18585]:STATEMENT: SELECT * from pgbench_accounts ORDER by bid;
2022-07-07 23:04:16 UTC:@:[18586]:LOG: temporary file: path "base/pgsql_tmp/pgsql_tmp18586.0", size
2022-07-07 23:04:16 UTC:@:[18586]:STATEMENT: SELECT * from pgbench_accounts ORDER by bid;
2022-07-07 23:04:16 UTC:54.240.198.34(12096):postgres@labdb:[5700]:LOG: temporary file: path "base/pg
2022-07-07 23:04:16 UTC:54.240.198.34(12096):postgres@labdb:[5700]:STATEMENT: SELECT * from pgbench_a
2022-07-07 23:06:02 UTC:[local]:[unknown]@[unknown]:[26796]:LOG: connection received: host=[local]
2022-07-07 23:08:02 UTC:[local]:[unknown]@[unknown]:[331]:LOG: connection received: host=[local]
2022-07-07 23:10:02 UTC:[local]:[unknown]@[unknown]:[5938]:LOG: connection received: host=[local]
2022-07-07 23:12:02 UTC:[local]:[unknown]@[unknown]:[11851]:LOG: connection received: host=[local]
2022-07-07 23:14:02 UTC:[local]:[unknown]@[unknown]:[17375]:LOG: connection received: host=[local]
2022-07-07 23:16:02 UTC:[local]:[unknown]@[unknown]:[22962]:LOG: connection received: host=[local]
2022-07-07 23:18:02 UTC:[local]:[unknown]@[unknown]:[28804]:LOG: connection received: host=[local]
2022-07-07 23:20:02 UTC:[local]:[unknown]@[unknown]:[2012]:LOG: connection received: host=[local]
2022-07-07 23:22:02 UTC:[local]:[unknown]@[unknown]:[180001]:LOG: connection received: host=[local]
```

You can configure this parameter differently for individuals and groups, based on your operational needs. For example, you can set the `work_mem` parameter to 8 GB for the role named `dev_team`.

```
postgres=> ALTER ROLE dev_team SET work_mem='8GB';
```

With this setting for `work_mem`, any role that's a member of the `dev_team` role is allotted up to 8 GB of working memory.

## Using indexes for faster response time

If your queries are taking too long to return results, you can verify that your indexes are being used as expected. First, turn on `\timing`, the `psql` metacommand, as follows.

```
postgres=> \timing on
```

After turning on timing, use a simple `SELECT` statement.

```
postgres=> SELECT COUNT(*) FROM
  (SELECT * FROM pgbench_accounts
   ORDER BY bid)
   AS accounts;
count
-----
5000000
(1 row)
Time: 3119.049 ms (00:03.119)
```

As shown in the output, this query took just over 3 seconds to complete. To improve the response time, create an index on `pgbench_accounts`, as follows.

```
postgres=> CREATE INDEX ON pgbench_accounts(bid);
CREATE INDEX
```

Rerun the query, and notice the faster response time. In this example, the query completed about 5 times faster, in about half a second.

```
postgres=> SELECT COUNT(*) FROM (SELECT * FROM pgbench_accounts ORDER BY bid) AS accounts;
count
-----
5000000
(1 row)
Time: 567.095 ms
```

## Adjusting working memory for logical decoding

Logical replication has been available in all versions of Aurora PostgreSQL since its introduction in PostgreSQL version 10. When you configure logical replication, you can also set the `logical_decoding_work_mem` parameter to specify the amount of memory that the logical decoding process can use for the decoding and streaming process.

During logical decoding, write-ahead log (WAL) records are converted to SQL statements that are then sent to another target for logical replication or another task. When a transaction is written to the WAL and then converted, the entire transaction must fit into the value specified for `logical_decoding_work_mem`. By default, this parameter is set to 64 MB. Any overflow is written to disk. This means that it must be reread from the disk before it can be sent to its destination, thus slowing the overall process.

You can assess the amount of transaction overflow in your current workload at a specific point in time by using the `aurora_stat_file` function as shown in the following example.

```
SELECT split_part (filename, '/', 2)
  AS slot_name, count(1) AS num_spill_files,
  sum(used_bytes) AS slot_total_bytes,
```

```

pg_size.pretty(sum(used_bytes)) AS slot_total_size
FROM aurora_stat_file()
WHERE filename like '%spill%'
GROUP BY 1;
slot_name | num_spill_files | slot_total_bytes | slot_total_size
-----+-----+-----+-----+
slot_name |      590      | 411600000 | 393 MB
(1 row)

```

This query returns the count and size of spill files on your Aurora PostgreSQL DB cluster when the query is invoked. Longer running workloads might not have any spill files on disk yet. To profile long-running workloads, we recommend that you create a table to capture the spill file information as the workload runs. You can create the table as follows.

```

CREATE TABLE spill_file_tracking AS
SELECT now() AS spill_time,*
FROM aurora_stat_file()
WHERE filename LIKE '%spill%';

```

To see how spill files are used during logical replication, set up a publisher and subscriber and then start a simple replication. For more information, see [Configuring logical replication \(p. 1225\)](#). With replication under way, you can create a job that captures the result set from the `aurora_stat_file()` spill file function, as follows.

```

INSERT INTO spill_file_tracking
SELECT now(),*
FROM aurora_stat_file()
WHERE filename LIKE '%spill%';

```

Use the following `psql` command to run the job once per second.

```
\watch 0.5
```

As the job is running, connect to the writer instance from another `psql` session. Use the following series of statements to run a workload that exceeds the memory configuration and causes Aurora PostgreSQL to create a spill file.

```

labdb=> CREATE TABLE my_table (a int PRIMARY KEY, b int);
CREATE TABLE
labdb=> INSERT INTO my_table SELECT x,x FROM generate_series(0,10000000) x;
INSERT 0 10000001
labdb=> UPDATE my_table SET b=b+1;
UPDATE 10000001

```

These statements take several minutes to complete. When finished, press the Ctrl key and the C key together to stop the monitoring function. Then use the following command to create a table to hold the information about the Aurora PostgreSQL DB cluster's spill file usage.

```

SELECT spill_time, split_part (filename, '/', 2)
AS slot_name, count(1)
AS spills, sum(used_bytes)
AS slot_total_bytes, pg_size.pretty(sum(used_bytes))
AS slot_total_size FROM spill_file_tracking
GROUP BY 1,2 ORDER BY 1;
spill_time | slot_name | spills | slot_total_bytes |
slot_total_size
-----+-----+-----+-----+
2022-04-15 13:42:52.528272+00 | replication_slot_name | 1 | 142352280 | 136 MB

```

2022-04-15 14:11:33.962216+00	replication_slot_name   4	467637996	446 MB
2022-04-15 14:12:00.997636+00	replication_slot_name   4	569409176	543 MB
2022-04-15 14:12:03.030245+00	replication_slot_name   4	569409176	543 MB
2022-04-15 14:12:05.059761+00	replication_slot_name   5	618410996	590 MB
2022-04-15 14:12:07.22905+00	replication_slot_name   5	640585316	611 MB
(6 rows)			

The output shows that running the example created five spill files that used 611 MB of memory. To avoid writing to disk, we recommend setting the `logical_decoding_work_mem` parameter to the next highest memory size, 1024.

## Replication with Amazon Aurora PostgreSQL

Following, you can find a description of replication with Amazon Aurora PostgreSQL, including how to monitor replication.

### Topics

- [Using Aurora Replicas \(p. 1224\)](#)
- [Monitoring Aurora PostgreSQL replication \(p. 1224\)](#)
- [Using PostgreSQL logical replication with Aurora \(p. 1225\)](#)

## Using Aurora Replicas

An *Aurora Replica* is an independent endpoint in an Aurora DB cluster, best used for scaling read operations and increasing availability. An Aurora DB cluster can include up to 15 Aurora Replicas located throughout the Availability Zones of the Aurora DB cluster's AWS Region.

The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the data in the cluster volume is represented as a single, logical volume to the primary writer DB instance and to Aurora Replicas in the DB cluster. For more information about Aurora Replicas, see [Aurora Replicas \(p. 73\)](#).

Aurora Replicas work well for read scaling because they're fully dedicated to read operations on your cluster volume. The writer DB instance manages write operations. The cluster volume is shared among all instances in your Aurora PostgreSQL DB cluster. Thus, no extra work is needed to replicate a copy of the data for each Aurora Replica.

With Aurora PostgreSQL, when an Aurora Replica is deleted, its instance endpoint is removed immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements running on the Aurora Replica that is being deleted, there is a three minute grace period. Existing statements can finish gracefully during the grace period. When the grace period ends, the Aurora Replica is shut down and deleted.

Aurora PostgreSQL DB clusters don't support Aurora Replicas in different AWS Regions, so you can't use Aurora Replicas for cross-Region replication.

### Note

Rebooting the writer DB instance of an Amazon Aurora DB cluster also automatically reboots the Aurora Replicas for that DB cluster. The automatic reboot re-establishes an entry point that guarantees read/write consistency across the DB cluster.

## Monitoring Aurora PostgreSQL replication

Read scaling and high availability depend on minimal lag time. You can monitor how far an Aurora Replica is lagging behind the writer DB instance of your Aurora PostgreSQL DB cluster by monitoring the

Amazon CloudWatch `ReplicaLag` metric. Because Aurora Replicas read from the same cluster volume as the writer DB instance, the `ReplicaLag` metric has a different meaning for an Aurora PostgreSQL DB cluster. The `ReplicaLag` metric for an Aurora Replica indicates the lag for the page cache of the Aurora Replica compared to that of the writer DB instance.

For more information on monitoring RDS instances and CloudWatch metrics, see [Monitoring metrics in an Amazon Aurora cluster \(p. 427\)](#).

## Using PostgreSQL logical replication with Aurora

PostgreSQL logical replication provides fine-grained control over replicating and synchronizing parts of a database. For example, you can use logical replication to replicate an individual table of a database.

Following, you can find information about how to work with PostgreSQL logical replication and Amazon Aurora. For more detailed information about the PostgreSQL implementation of logical replication, see [Logical replication](#) and [Logical decoding concepts](#) in the PostgreSQL documentation.

### Note

Logical replication is available with Aurora PostgreSQL version 2.2.0 (compatible with PostgreSQL 10.6) and later.

Following, you can find information about how to work with PostgreSQL logical replication and Amazon Aurora.

### Topics

- [Configuring logical replication \(p. 1225\)](#)
- [Example of logical replication of a database table \(p. 1227\)](#)
- [Logical replication using the AWS Database Migration Service \(p. 1228\)](#)
- [Stopping logical replication \(p. 1229\)](#)

## Configuring logical replication

To use logical replication, you first set the `rds.logical_replication` parameter for a cluster parameter group. You then set up the publisher and subscriber.

Logical replication uses a publish and subscribe model. *Publishers* and *subscribers* are the nodes. A *publication* is a set of changes generated from one or more database tables. You specify a publication on a publisher. A *subscription* defines the connection to another database and one or more publications to which it subscribes. You specify a subscription on a subscriber. The publication and subscription make the connection between the publisher and subscriber. The replication process uses a *replication slot* to track the progress of a subscription.

### Note

Following are requirements for logical replication:

- To set up logical replication, you need to have `rds_superuser` permissions.
- The source instance (publisher node) and the receiving instance (subscriber node) must each have automated backups turned on. For more information, see [Enabling automated backups](#) in the *Amazon RDS User Guide*.

### To enable PostgreSQL logical replication with Aurora

1. Create a new DB cluster parameter group to use for logical replication, as described in [Creating a DB cluster parameter group \(p. 219\)](#). Use the following settings:

- For **Parameter group family**, choose your version of Aurora PostgreSQL, such as **aurora-postgresql12**.
  - For **Type**, choose **DB Cluster Parameter Group**.
2. Modify the DB cluster parameter group, as described in [Modifying parameters in a DB cluster parameter group \(p. 221\)](#). Set the `rds.logical_replication` static parameter to 1.
- Enabling the `rds.logical_replication` parameter affects the DB cluster's performance.
3. Review the `max_replication_slots`, `max_wal_senders`, `max_logical_replication_workers`, and `max_worker_processes` parameters in your DB cluster parameter group based on your expected usage. If necessary, modify the DB cluster parameter group to change the settings for these parameters, as described in [Modifying parameters in a DB cluster parameter group \(p. 221\)](#).

Follow these guidelines for setting the parameters:

- `max_replication_slots` – A *replication slot* tracks the progress of a subscription. Set the value of the `max_replication_slots` parameter to the total number of subscriptions that you plan to create. If you are using AWS DMS, set this parameter to the number of AWS DMS tasks that you plan to use for change data capture from this DB cluster.
- `max_wal_senders` and `max_logical_replication_workers` – Ensure that `max_wal_senders` and `max_logical_replication_workers` are each set at least as high as the number of logical replication slots that you intend to be active, or the number of active AWS DMS tasks for change data capture. Leaving a logical replication slot inactive prevents the vacuum from removing obsolete tuples from tables, so we recommend that you don't keep inactive replication slots for long periods of time.
- `max_worker_processes` – Ensure that `max_worker_processes` is at least as high as the combined values of `max_logical_replication_workers`, `autovacuum_max_workers`, and `max_parallel_workers`. Having a high number of background worker processes might affect application workloads on small DB instance classes, so monitor the performance of your database if you set `max_worker_processes` higher than the default value.

## To configure a publisher for logical replication

1. Set the publisher's cluster parameter group:
  - To use an existing Aurora PostgreSQL DB cluster for the publisher, the engine version must be 10.6 or later. Do the following:
    1. Modify the DB cluster parameter group to set it to the group that you created when you enabled logical replication. For details about modifying an Aurora PostgreSQL DB cluster, see [Modifying an Amazon Aurora DB cluster \(p. 248\)](#).
    2. Restart the DB cluster for static parameter changes to take effect. The DB cluster parameter group includes a change to the static parameter `rds.logical_replication`.
  - To use a new Aurora PostgreSQL DB cluster for the publisher, create the DB cluster using the following settings. For details about creating an Aurora PostgreSQL DB cluster, see [Creating a DB cluster \(p. 131\)](#).
    1. Choose the **Amazon Aurora** engine and choose the **PostgreSQL-compatible** edition.
    2. For **Engine version**, choose an Aurora PostgreSQL engine that is compatible with PostgreSQL 10.6 or greater.
    3. For **DB cluster parameter group**, choose the group that you created when you enabled logical replication.
2. Modify the inbound rules of the security group for the publisher to allow the subscriber to connect. Usually, you do this by including the IP address of the subscriber in the security group. For details

about modifying a security group, see [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.

## Example of logical replication of a database table

To implement logical replication, use the PostgreSQL commands `CREATE PUBLICATION` and `CREATE SUBSCRIPTION`.

For this example, table data is replicated from an Aurora PostgreSQL database as the publisher to a PostgreSQL database as the subscriber. Note that a subscriber database can be an RDS PostgreSQL database or an Aurora PostgreSQL database. A subscriber can also be an application that uses PostgreSQL logical replication. After the logical replication mechanism is set up, changes on the publisher are continually sent to the subscriber as they occur.

To set up logical replication for this example, do the following:

1. Configure an Aurora PostgreSQL DB cluster as the publisher. To do so, create a new Aurora PostgreSQL DB cluster, as described when configuring the publisher in [Configuring logical replication \(p. 1225\)](#).
2. Set up the publisher database.

For example, create a table using the following SQL statement on the publisher database.

```
CREATE TABLE LogicalReplicationTest (a int PRIMARY KEY);
```

3. Insert data into the publisher database by using the following SQL statement.

```
INSERT INTO LogicalReplicationTest VALUES (generate_series(1,10000));
```

4. Create a publication on the publisher by using the following SQL statement.

```
CREATE PUBLICATION testpub FOR TABLE LogicalReplicationTest;
```

5. Create your subscriber. A subscriber database can be either of the following:

- Aurora PostgreSQL database version 2.2.0 (compatible with PostgreSQL 10.6) or later.
- Amazon RDS for PostgreSQL database with the PostgreSQL DB engine version 10.4 or later.

For this example, we create an Amazon RDS for PostgreSQL database as the subscriber. For details on creating a DB instance, see [Creating a DB instance](#) in the *Amazon RDS User Guide*.

6. Set up the subscriber database.

For this example, create a table like the one created for the publisher by using the following SQL statement.

```
CREATE TABLE LogicalReplicationTest (a int PRIMARY KEY);
```

7. Verify that there is data in the table at the publisher but no data yet at the subscriber by using the following SQL statement on both databases.

```
SELECT count(*) FROM LogicalReplicationTest;
```

8. Create a subscription on the subscriber.

Use the following SQL statement on the subscriber database and the following settings from the publisher cluster:

- **host** – The publisher cluster's writer DB instance.

- **port** – The port on which the writer DB instance is listening. The default for PostgreSQL is 5432.
- **dbname** – The DB name of the publisher cluster.

```
CREATE SUBSCRIPTION testsub CONNECTION
  'host=publisher-cluster-writer-endpoint port=5432 dbname=db-name user=user
  password=password'
  PUBLICATION testpub;
```

After the subscription is created, a logical replication slot is created at the publisher.

9. To verify for this example that the initial data is replicated on the subscriber, use the following SQL statement on the subscriber database.

```
SELECT count(*) FROM LogicalReplicationTest;
```

Any further changes on the publisher are replicated to the subscriber.

## Logical replication using the AWS Database Migration Service

You can use the AWS Database Migration Service (AWS DMS) to replicate a database or a portion of a database. Use AWS DMS to migrate your data from an Aurora PostgreSQL database to another open source or commercial database. For more information about AWS DMS, see the [AWS Database Migration Service User Guide](#).

The following example shows how to set up logical replication from an Aurora PostgreSQL database as the publisher and then use AWS DMS for migration. This example uses the same publisher and subscriber that were created in [Example of logical replication of a database table \(p. 1227\)](#).

To set up logical replication with AWS DMS, you need details about your publisher and subscriber from Amazon RDS. In particular, you need details about the publisher's writer DB instance and the subscriber's DB instance.

Get the following information for the publisher's writer DB instance:

- The virtual private cloud (VPC) identifier
- The subnet group
- The Availability Zone (AZ)
- The VPC security group
- The DB instance ID

Get the following information for the subscriber's DB instance:

- The DB instance ID
- The source engine

### To use AWS DMS for logical replication with Aurora PostgreSQL

1. Prepare the publisher database to work with AWS DMS.

To do this, PostgreSQL 10.x and later databases require that you apply AWS DMS wrapper functions to the publisher database. For details on this and later steps, see the instructions in [Using PostgreSQL version 10.x and later as a source for AWS DMS](#) in the *AWS Database Migration Service User Guide*.

2. Sign in to the AWS Management Console and open the AWS DMS console at <https://console.aws.amazon.com/dms/v2>. At top right, choose the same AWS Region in which the publisher and subscriber are located.
3. Create an AWS DMS replication instance.

Choose values that are the same as for your publisher's writer DB instance. These include the following settings:

- For **VPC**, choose the same VPC as for the writer DB instance.
  - For **Replication Subnet Group**, choose a subnet group with the same values as the writer DB instance. Create a new one if necessary.
  - For **Availability zone**, choose the same zone as for the writer DB instance.
  - For **VPC Security Group**, choose the same group as for the writer DB instance.
4. Create an AWS DMS endpoint for the source.

Specify the publisher as the source endpoint by using the following settings:

- For **Endpoint type**, choose **Source endpoint**.
  - Choose **Select RDS DB Instance**.
  - For **RDS Instance**, choose the DB identifier of the publisher's writer DB instance.
  - For **Source engine**, choose **postgres**.
5. Create an AWS DMS endpoint for the target.

Specify the subscriber as the target endpoint by using the following settings:

- For **Endpoint type**, choose **Target endpoint**.
  - Choose **Select RDS DB Instance**.
  - For **RDS Instance**, choose the DB identifier of the subscriber DB instance.
  - Choose a value for **Source engine**. For example, if the subscriber is an RDS PostgreSQL database, choose **postgres**. If the subscriber is an Aurora PostgreSQL database, choose **aurora-postgresql**.
6. Create an AWS DMS database migration task.

You use a database migration task to specify what database tables to migrate, to map data using the target schema, and to create new tables on the target database. At a minimum, use the following settings for **Task configuration**:

- For **Replication instance**, choose the replication instance that you created in an earlier step.
- For **Source database endpoint**, choose the publisher source that you created in an earlier step.
- For **Target database endpoint**, choose the subscriber target that you created in an earlier step.

The rest of the task details depend on your migration project. For more information about specifying all the details for DMS tasks, see [Working with AWS DMS tasks](#) in the *AWS Database Migration Service User Guide*.

After AWS DMS creates the task, it begins migrating data from the publisher to the subscriber.

## Stopping logical replication

You can stop using logical replication.

### To stop using logical replication

1. Drop all replication slots.

To drop all of the replication slots, connect to the publisher and run the following SQL command

```
SELECT pg_drop_replication_slot(slot_name) FROM pg_replication_slots
WHERE slot_name IN (SELECT slot_name FROM pg_replication_slots);
```

The replication slots can't be active when you run this command.

2. Modify the DB cluster parameter group associated with the publisher, as described in [Modifying parameters in a DB cluster parameter group \(p. 221\)](#). Set the `rds.logical_replication static` parameter to 0.
3. Restart the publisher DB cluster for the change to the `rds.logical_replication static` parameter to take effect.

## Integrating Amazon Aurora PostgreSQL with other AWS services

Amazon Aurora integrates with other AWS services so that you can extend your Aurora PostgreSQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora PostgreSQL DB cluster can use AWS services to do the following:

- Quickly collect, view, and assess performance for your Aurora PostgreSQL DB instances with Amazon RDS Performance Insights. Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information about Performance Insights, see [Monitoring DB load with Performance Insights on Amazon Aurora \(p. 461\)](#).
- Configure your Aurora PostgreSQL DB cluster to publish log data to Amazon CloudWatch Logs. CloudWatch Logs provide highly durable storage for your log records. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. For more information, see [Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs \(p. 1265\)](#).
- Import data from an Amazon S3 bucket to an Aurora PostgreSQL DB cluster, or export data from an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. For more information, see [Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster \(p. 1230\)](#) and [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3 \(p. 1243\)](#).
- Add machine learning-based predictions to database applications using the SQL language. Aurora machine learning uses a highly optimized integration between the Aurora database and the AWS machine learning (ML) services SageMaker and Amazon Comprehend. For more information, see [Using machine learning \(ML\) with Aurora PostgreSQL \(p. 1272\)](#).
- Invoke AWS Lambda functions from an Aurora PostgreSQL DB cluster. To do this, use the `aws_lambda` PostgreSQL extension provided with Aurora PostgreSQL. For more information, see [Invoking an AWS Lambda function from an Aurora PostgreSQL DB cluster \(p. 1254\)](#).
- Integrate queries from Amazon Redshift and Aurora PostgreSQL. For more information, see [Getting started with using federated queries to PostgreSQL](#) in the *Amazon Redshift Database Developer Guide*.

## Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster

You can import data that's been stored using Amazon Simple Storage Service into a table on an Aurora PostgreSQL DB cluster instance. To do this, you first install the Aurora PostgreSQL `aws_s3` extension. This extension provides the functions that you use to import data from an Amazon S3 bucket. A *bucket*

is an Amazon S3 container for objects and files. The data can be in a comma-separated value (CSV) file, a text file, or a compressed (gzip) file. Following, you can learn how to install the extension and how to import data from Amazon S3 into a table.

Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into Aurora PostgreSQL.

If you don't have data stored on Amazon S3, you need to first create a bucket and store the data. For more information, see the following topics in the *Amazon Simple Storage Service User Guide*.

- [Create a bucket](#)
- [Add an object to a bucket](#)

**Note**

Importing data from Amazon S3 isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

**Topics**

- [Installing the aws\\_s3 extension \(p. 1231\)](#)
- [Overview of importing data from Amazon S3 data \(p. 1232\)](#)
- [Setting up access to an Amazon S3 bucket \(p. 1233\)](#)
- [Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster \(p. 1238\)](#)
- [Function reference \(p. 1240\)](#)

## Installing the aws\_s3 extension

Before you can use Amazon S3 with your Aurora PostgreSQL DB cluster, you need to install the `aws_s3` extension. This extension provides functions for importing data from an Amazon S3. It also provides functions for exporting data from an instance of an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. For more information, see [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3 \(p. 1243\)](#). The `aws_s3` extension depends on some of the helper functions in the `aws_commons` extension, which is installed automatically when needed.

### To install the aws\_s3 extension

1. Use `psql` (or `pgAdmin`) to connect to the writer instance of your Aurora PostgreSQL DB cluster as a user that has `rds_superuser` privileges. If you kept the default name during the setup process, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres  
--password
```

2. To install the extension, run the following command.

```
postgres=> CREATE EXTENSION aws_s3 CASCADE;  
NOTICE: installing required extension "aws_commons"  
CREATE EXTENSION
```

3. To verify that the extension is installed, you can use the `\dx` metacommand.

```
postgres=> \dx  
      List of installed extensions  
 Name | Version | Schema | Description  
-----+-----+-----+  
aws_commons | 1.2 | public | Common data types across AWS services
```

```
aws_s3      | 1.1      | public      | AWS S3 extension for importing data from S3
plpgsql     | 1.0      | pg_catalog  | PL/pgSQL procedural language
(3 rows)
```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

## Overview of importing data from Amazon S3 data

### To import S3 data into Aurora PostgreSQL

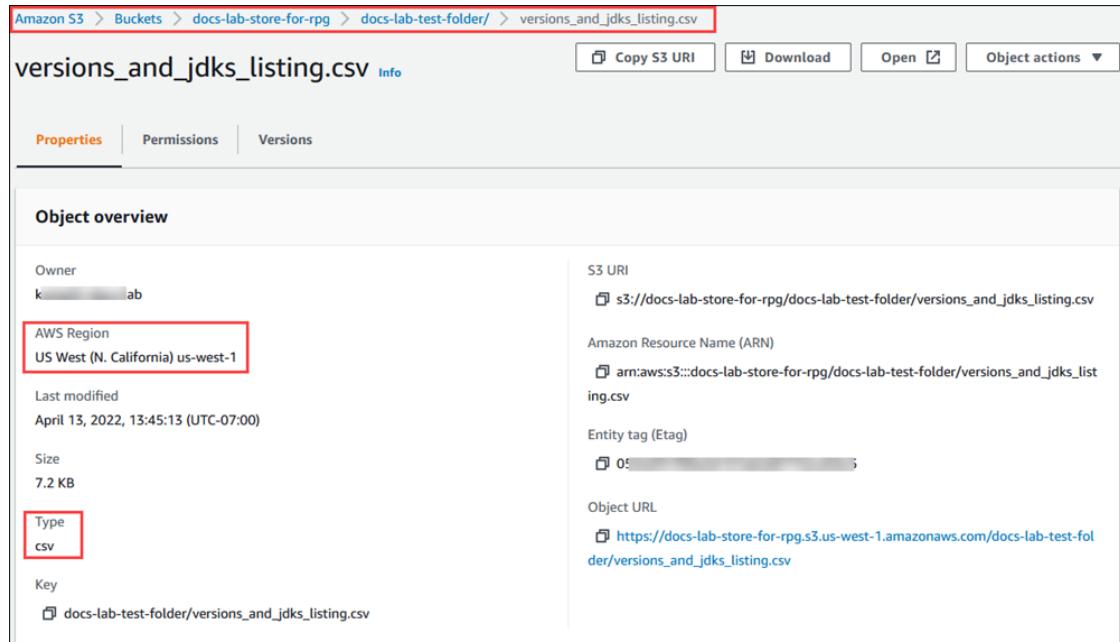

First, gather the details that you need to supply to the function. These include the name of the table on your Aurora PostgreSQL DB cluster's instance, and the bucket name, file path, file type, and AWS Region where the Amazon S3 data is stored. For more information, see [View an object](#) in the *Amazon Simple Storage Service User Guide*.

1. Get the name of the table into which the `aws_s3.table_import_from_s3` function is to import the data. As an example, the following creates a database `t1` that can be used in later steps.

```
postgres=> CREATE TABLE t1
  (col1 varchar(80),
   col2 varchar(80),
   col3 varchar(80));
```

2. Get the details about the Amazon S3 bucket and the data to import. To do this, open the Amazon S3 console at <https://console.aws.amazon.com/s3/>, and choose **Buckets**. Find the bucket containing your data in the list. Choose the bucket, open its Object overview page, and then choose Properties.

Make a note of the bucket name, path, the AWS Region, and file type. You need the Amazon Resource Name (ARN) later, to set up access to Amazon S3 through an IAM role. For more information, see [Setting up access to an Amazon S3 bucket \(p. 1233\)](#). The image following shows an example.

3. You can verify the path to the data on the Amazon S3 bucket by using the AWS CLI command `aws s3 cp`. If the information is correct, this command downloads a copy of the Amazon S3 file.

```
aws s3 cp s3://sample_s3_bucket/sample_file_path ./
```

4. Set up permissions on your Aurora PostgreSQL DB cluster to allow access to the file on the Amazon S3 bucket. To do so, you use either an AWS Identity and Access Management (IAM) role or security credentials. For more information, see [Setting up access to an Amazon S3 bucket \(p. 1233\)](#).
5. Supply the path and other Amazon S3 object details gathered (see step 2) to the `create_s3_uri` function to construct an Amazon S3 URI object. To learn more about this function, see [aws\\_commons.create\\_s3\\_uri \(p. 1242\)](#). The following is an example of constructing this object during a `psql` session.

```
postgres=> SELECT aws_commons.create_s3_uri(  
    'docs-lab-store-for-rpg',  
    'versions_and_jdks_listing.csv',  
    'us-west-1'  
) AS s3_uri \gset
```

In the next step, you pass this object (`aws_commons._s3_uri_1`) to the `aws_s3.table_import_from_s3` function to import the data to the table.

6. Invoke the `aws_s3.table_import_from_s3` function to import the data from Amazon S3 into your table. For reference information, see [aws\\_s3.table\\_import\\_from\\_s3 \(p. 1240\)](#). For examples, see [Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster \(p. 1238\)](#).

## Setting up access to an Amazon S3 bucket

To import data from an Amazon S3 file, give the Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

### Topics

- [Using an IAM role to access an Amazon S3 bucket \(p. 1233\)](#)
- [Using security credentials to access an Amazon S3 bucket \(p. 1237\)](#)
- [Troubleshooting access to Amazon S3 \(p. 1238\)](#)

## Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket the file is in. This way, you don't have to manage additional credential information or provide it in the `aws_s3.table_import_from_s3 (p. 1240)` function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB cluster.

### Note

You can't associate an IAM role with an Aurora Serverless v1 DB cluster, so the following steps don't apply.

### To give an Aurora PostgreSQL DB cluster access to Amazon S3 through an IAM role

1. Create an IAM policy.

This policy provides the bucket and object permissions that allow your Aurora PostgreSQL DB cluster to access Amazon S3.

Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Aurora PostgreSQL:

- s3:GetObject
- s3>ListBucket

Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

- arn:aws:s3:::*your-s3-bucket*
- arn:aws:s3:::*your-s3-bucket*/\*

For more information on creating an IAM policy for Aurora PostgreSQL, see [Creating and using an IAM policy for IAM database access \(p. 1686\)](#). See also [Tutorial: Create and attach your first customer managed policy](#) in the *IAM User Guide*.

The following AWS CLI command creates an IAM policy named `rds-s3-import-policy` with these options. It grants access to a bucket named `your-s3-bucket`.

**Note**

Make a note of the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN in a subsequent step when you attach the policy to an IAM role.

### Example

For Linux, macOS, or Unix:

```
aws iam create-policy \
--policy-name rds-s3-import-policy \
--policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "s3import",
            "Action": [
                "s3:GetObject",
                "s3>ListBucket"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3:::your-s3-bucket",
                "arn:aws:s3:::your-s3-bucket/*"
            ]
        }
    ]
}'
```

For Windows:

```
aws iam create-policy ^
--policy-name rds-s3-import-policy ^
--policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "s3import",
            "Action": [
                "s3:GetObject",
                "s3>ListBucket"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:s3:::your-s3-bucket",
                "arn:aws:s3:::your-s3-bucket/*"
            ]
        }
    ]
}'
```

```
    "Resource": [
        "arn:aws:s3:::your-s3-bucket",
        "arn:aws:s3:::your-s3-bucket/*"
    ]
}
}'
```

2. Create an IAM role.

You do this so Aurora PostgreSQL can assume this IAM role to access your Amazon S3 buckets. For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the [confused deputy problem](#).

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-import-role`.

### Example

For Linux, macOS, or Unix:

```
aws iam create-role \
--role-name rds-s3-import-role \
--assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111122223333",
                    "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
                }
            }
        }
    ]
}'
```

For Windows:

```
aws iam create-role ^
--role-name rds-s3-import-role ^
--assume-role-policy-document '{
    "Version": "2012-10-17",
```

```
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
            "StringEquals": {
                "aws:SourceAccount": "111122223333",
                "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
            }
        }
    }
]
```

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created in the previous step to the role named `rds-s3-import-role`. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

### Example

For Linux, macOS, or Unix:

```
aws iam attach-role-policy \
--policy-arn your-policy-arn \
--role-name rds-s3-import-role
```

For Windows:

```
aws iam attach-role-policy ^
--policy-arn your-policy-arn ^
--role-name rds-s3-import-role
```

4. Add the IAM role to the DB cluster.

You do so by using the AWS Management Console or AWS CLI, as described following.

### Console

#### To add an IAM role for a PostgreSQL DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the PostgreSQL DB cluster name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this cluster**.
4. Under **Feature**, choose **s3Import**.
5. Choose **Add role**.

## AWS CLI

### To add an IAM role for a PostgreSQL DB cluster using the CLI

- Use the following command to add the role to the PostgreSQL DB cluster named `my-db-cluster`. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use `s3Import` for the value of the `--feature-name` option.

#### Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-cluster \
--db-cluster-identifier my-db-cluster \
--feature-name s3Import \
--role-arn your-role-arn \
--region your-region
```

For Windows:

```
aws rds add-role-to-db-cluster ^
--db-cluster-identifier my-db-cluster ^
--feature-name s3Import ^
--role-arn your-role-arn ^
--region your-region
```

## RDS API

To add an IAM role for a PostgreSQL DB cluster using the Amazon RDS API, call the [AddRoleToDBCluster](#) operation.

### Using security credentials to access an Amazon S3 bucket

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. You do so by specifying the `credentials` parameter in the [aws\\_s3.table\\_import\\_from\\_s3](#) (p. 1240) function call.

The `credentials` parameter is a structure of type `aws_commons._aws_credentials_1`, which contains AWS credentials. Use the [aws\\_commons.create\\_aws\\_credentials](#) (p. 1243) function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.

```
postgres=> SELECT aws_commons.create_aws_credentials(
  'sample_access_key', 'sample_secret_key', '')
AS creds \gset
```

After creating the `aws_commons._aws_credentials_1` structure, use the [aws\\_s3.table\\_import\\_from\\_s3](#) (p. 1240) function with the `credentials` parameter to import the data, as shown following.

```
postgres=> SELECT aws_s3.table_import_from_s3(
  't', '', '(format csv)',
  :'s3_uri',
  :'creds'
);
```

Or you can include the [aws\\_commons.create\\_aws\\_credentials](#) (p. 1243) function call inline within the `aws_s3.table_import_from_s3` function call.

```
postgres=> SELECT aws_s3.table_import_from_s3(
    't', '',
    '(format csv)',
    :'s3_uri',
    aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', '')
);
```

## Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to import data from Amazon S3, see the following for recommendations:

- [Troubleshooting Amazon Aurora identity and access \(p. 1710\)](#)
- [Troubleshooting Amazon S3 in the Amazon Simple Storage Service User Guide](#)
- [Troubleshooting Amazon S3 and IAM in the IAM User Guide](#)

## Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster

You import data from your Amazon S3 bucket by using the `table_import_from_s3` function of the `aws_s3` extension. For reference information, see [aws\\_s3.table\\_import\\_from\\_s3 \(p. 1240\)](#).

### Note

The following examples use the IAM role method to allow access to the Amazon S3 bucket. Thus, the `aws_s3.table_import_from_s3` function calls don't include credential parameters.

The following shows a typical example.

```
postgres=> SELECT aws_s3.table_import_from_s3(
    't1',
    '',
    '(format csv)',
    :'s3_uri'
);
```

The parameters are the following:

- `t1` – The name for the table in the PostgreSQL DB cluster to copy the data into.
- `''` – An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see [Importing an Amazon S3 file that uses a custom delimiter \(p. 1239\)](#).
- `(format csv)` – PostgreSQL COPY arguments. The copy process uses the arguments and format of the [PostgreSQL COPY](#) command to import the data. Choices for format include comma-separated value (CSV) as shown in this example, text, and binary. The default is text.
- `s3_uri` – A structure that contains the information identifying the Amazon S3 file. For an example of using the `aws_commons.create_s3_uri (p. 1242)` function to create an `s3_uri` structure, see [Overview of importing data from Amazon S3 data \(p. 1232\)](#).

For more information about this function, see [aws\\_s3.table\\_import\\_from\\_s3 \(p. 1240\)](#).

The `aws_s3.table_import_from_s3` function returns text. To specify other kinds of files for import from an Amazon S3 bucket, see one of the following examples.

### Topics

- [Importing an Amazon S3 file that uses a custom delimiter \(p. 1239\)](#)
- [Importing an Amazon S3 compressed \(gzip\) file \(p. 1239\)](#)
- [Importing an encoded Amazon S3 file \(p. 1240\)](#)

## Importing an Amazon S3 file that uses a custom delimiter

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the `column_list` parameter of the [aws\\_s3.table\\_import\\_from\\_s3 \(p. 1240\)](#) function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.

```
1|foo1|bar1|elephant1
2|foo2|bar2|elephant2
3|foo3|bar3|elephant3
4|foo4|bar4|elephant4
...
```

### To import a file that uses a custom delimiter

1. Create a table in the database for the imported data.

```
postgres=> CREATE TABLE test (a text, b text, c text, d text, e text);
```

2. Use the following form of the [aws\\_s3.table\\_import\\_from\\_s3 \(p. 1240\)](#) function to import data from the Amazon S3 file.

You can include the [aws\\_commons.create\\_s3\\_uri \(p. 1242\)](#) function call inline within the `aws_s3.table_import_from_s3` function call to specify the file.

```
postgres=> SELECT aws_s3.table_import_from_s3(
    'test',
    'a,b,d,e',
    'DELIMITER ''|''',
    aws_commons.create_s3_uri('sampleBucket', 'pipeDelimitedSampleFile', 'us-east-2')
);
```

The data is now in the table in the following columns.

```
postgres=> SELECT * FROM test;
a | b | c | d | e
---+---+---+---+---
1 | foo1 | bar1 | elephant1
2 | foo2 | bar2 | elephant2
3 | foo3 | bar3 | elephant3
4 | foo4 | bar4 | elephant4
```

## Importing an Amazon S3 compressed (gzip) file

The following example shows how to import a file from Amazon S3 that is compressed with gzip. The file that you import needs to have the following Amazon S3 metadata:

- Key: Content-Encoding
- Value: gzip

If you upload the file using the AWS Management Console, the metadata is typically applied by the system. For information about uploading files to Amazon S3 using the AWS Management Console, the AWS CLI, or the API, see [Uploading objects in the Amazon Simple Storage Service User Guide](#).

For more information about Amazon S3 metadata and details about system-provided metadata, see [Editing object metadata in the Amazon S3 console](#) in the *Amazon Simple Storage Service User Guide*.

Import the gzip file into your Aurora PostgreSQL DB cluster as shown following.

```
postgres=> CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
postgres=> SELECT aws_s3.table_import_from_s3(
  'test_gzip', '', '(format csv)',
  'myS3Bucket', 'test-data.gz', 'us-east-2'
);
```

## Importing an encoded Amazon S3 file

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

```
postgres=> SELECT aws_s3.table_import_from_s3(
  'test_table', '', 'encoding ''WIN1252'''',
  aws_commons.create_s3_uri('sampleBucket', 'SampleFile', 'us-east-2')
);
```

## Function reference

### Functions

- [aws\\_s3.table\\_import\\_from\\_s3 \(p. 1240\)](#)
- [aws\\_commons.create\\_s3\\_uri \(p. 1242\)](#)
- [aws\\_commons.create\\_aws\\_credentials \(p. 1243\)](#)

### aws\_s3.table\_import\_from\_s3

Imports Amazon S3 data into an Aurora PostgreSQL table. The `aws_s3` extension provides the `aws_s3.table_import_from_s3` function. The return value is text.

#### Syntax

The required parameters are `table_name`, `column_list` and `options`. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

- The `s3_info` parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB cluster.

```
aws_s3.table_import_from_s3 (
    table_name text,
    column_list text,
    options text,
    s3_info aws_commons._s3_uri_1
)
```

- The `credentials` parameter specifies the credentials to access Amazon S3. When you use this parameter, you don't use an IAM role.

```
aws_s3.table_import_from_s3 (
```

```
    table_name text,
    column_list text,
    options text,
    s3_info aws_commons._s3_uri_1,
    credentials aws_commons._aws_credentials_1
)
```

## Parameters

### *table\_name*

A required text string containing the name of the PostgreSQL database table to import the data into.

### *column\_list*

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see [Importing an Amazon S3 file that uses a custom delimiter \(p. 1239\)](#).

### *options*

A required text string containing arguments for the PostgreSQL `COPY` command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the [PostgreSQL COPY documentation](#).

### *s3\_info*

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket containing the file.
- `file_path` – The Amazon S3 file name including the path of the file.
- `region` – The AWS Region that the file is in. For a listing of AWS Region names and associated values, see [Regions and Availability Zones \(p. 11\)](#).

### *credentials*

An `aws_commons._aws_credentials_1` composite type containing the following credentials to use for the import operation:

- Access key
- Secret key
- Session token

For information about creating an `aws_commons._aws_credentials_1` composite structure, see [aws\\_commons.create\\_aws\\_credentials \(p. 1243\)](#).

## Alternate syntax

To help with testing, you can use an expanded set of parameters instead of the `s3_info` and `credentials` parameters. Following are additional syntax variations for the `aws_s3.table_import_from_s3` function:

- Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```
aws_s3.table_import_from_s3 (
    table_name text,
```

```
    column_list text,
    options text,
    bucket text,
    file_path text,
    region text
)
```

- Instead of using the `credentials` parameter to specify Amazon S3 access, use the combination of the `access_key`, `session_key`, and `session_token` parameters.

```
aws_s3.table_import_from_s3 (
    table_name text,
    column_list text,
    options text,
    bucket text,
    file_path text,
    region text,
    access_key text,
    secret_key text,
    session_token text
)
```

## Alternate parameters

### *bucket*

A text string containing the name of the Amazon S3 bucket that contains the file.

### *file\_path*

A text string containing the Amazon S3 file name including the path of the file.

### *region*

A text string identifying the AWS Region location of the file. For a listing of AWS Region names and associated values, see [Regions and Availability Zones \(p. 11\)](#).

### *access\_key*

A text string containing the access key to use for the import operation. The default is NULL.

### *secret\_key*

A text string containing the secret key to use for the import operation. The default is NULL.

### *session\_token*

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

## [aws\\_commons.create\\_s3\\_uri](#)

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. Use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the [aws\\_s3.table\\_import\\_from\\_s3 \(p. 1240\)](#) function.

### Syntax

```
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
```

)

## Parameters

*bucket*

A required text string containing the Amazon S3 bucket name for the file.

*file\_path*

A required text string containing the Amazon S3 file name including the path of the file.

*region*

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see [Regions and Availability Zones \(p. 11\)](#).

## [aws\\_commons.create\\_aws\\_credentials](#)

Sets an access key and secret key in an `aws_commons._aws_credentials_1` structure. Use the results of the `aws_commons.create_aws_credentials` function in the `credentials` parameter of the [aws\\_s3.table\\_import\\_from\\_s3 \(p. 1240\)](#) function.

### Syntax

```
aws_commons.create_aws_credentials(  
    access_key text,  
    secret_key text,  
    session_token text  
)
```

## Parameters

*access\_key*

A required text string containing the access key to use for importing an Amazon S3 file. The default is NULL.

*secret\_key*

A required text string containing the secret key to use for importing an Amazon S3 file. The default is NULL.

*session\_token*

An optional text string containing the session token to use for importing an Amazon S3 file. The default is NULL. If you provide an optional `session_token`, you can use temporary credentials.

## Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3

You can query data from an Aurora PostgreSQL DB cluster and export it directly into files stored in an Amazon S3 bucket. To do this, you first install the Aurora PostgreSQL `aws_s3` extension. This extension provides you with the functions that you use to export the results of queries to Amazon S3. Following, you can find out how to install the extension and how to export data to Amazon S3.

You can export from a provisioned or an Aurora Serverless v2 DB instance. These steps aren't supported for Aurora Serverless v1.

All currently available versions of Aurora PostgreSQL support exporting data to Amazon Simple Storage Service. For detailed version information, see [Amazon Aurora PostgreSQL updates in the Release Notes for Aurora PostgreSQL](#).

If you don't have a bucket set up for your export, see the following topics the *Amazon Simple Storage Service User Guide*.

- [Setting up Amazon S3](#)
- [Create a bucket](#)

The upload to Amazon S3 uses server-side encryption by default. If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can't export data to a bucket that is encrypted with a customer managed key.

**Note**

You can save DB and DB cluster snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see [Exporting DB cluster snapshot data to Amazon S3 \(p. 396\)](#).

**Topics**

- [Installing the aws\\_s3 extension \(p. 1244\)](#)
- [Overview of exporting data to Amazon S3 \(p. 1245\)](#)
- [Specifying the Amazon S3 file path to export to \(p. 1245\)](#)
- [Setting up access to an Amazon S3 bucket \(p. 1246\)](#)
- [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function \(p. 1249\)](#)

## Installing the aws\_s3 extension

Before you can use Amazon Simple Storage Service with your Aurora PostgreSQL DB cluster, you need to install the aws\_s3 extension. This extension provides functions for exporting data from the writer instance of an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. It also provides functions for importing data from an Amazon S3. For more information, see [Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster \(p. 1230\)](#). The aws\_s3 extension depends on some of the helper functions in the aws\_commons extension, which is installed automatically when needed.

### To install the aws\_s3 extension

1. Use psql (or pgAdmin) to connect to the writer instance of your Aurora PostgreSQL DB cluster as a user that has rds\_superuser privileges. If you kept the default name during the setup process, you connect as postgres.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres  
--password
```

2. To install the extension, run the following command.

```
postgres=> CREATE EXTENSION aws_s3 CASCADE;  
NOTICE: installing required extension "aws_commons"  
CREATE EXTENSION
```

3. To verify that the extension is installed, you can use the psql \dx metacommand.

```
postgres=> \dx
```

List of installed extensions			
Name	Version	Schema	Description
aws_commons	1.2	public	Common data types across AWS services
aws_s3	1.1	public	AWS S3 extension for importing data from S3
plpgsql	1.0	pg_catalog	PL/pgSQL procedural language
(3 rows)			

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

## Verify that your Aurora PostgreSQL version supports exports to Amazon S3

You can verify that your Aurora PostgreSQL version supports export to Amazon S3 by using the `describe-db-engine-versions` command. The following example checks to see if version 10.14 can export to Amazon S3.

```
aws rds describe-db-engine-versions --region us-east-1 \  
--engine aurora-postgresql --engine-version 10.14 | grep s3Export
```

If the output includes the string "s3Export", then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

## Overview of exporting data to Amazon S3

To export data stored in an Aurora PostgreSQL database to an Amazon S3 bucket, use the following procedure.

### To export Aurora PostgreSQL data to S3

1. Identify an Amazon S3 file path to use for exporting data. For details about this process, see [Specifying the Amazon S3 file path to export to \(p. 1245\)](#).
2. Provide permission to access the Amazon S3 bucket.

To export data to an Amazon S3 file, give the Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:

1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
2. Create an IAM role.
3. Attach the policy you created to the role you created.
4. Add this IAM role to your DB cluster .

For details about this process, see [Setting up access to an Amazon S3 bucket \(p. 1246\)](#).

3. Identify a database query to get the data. Export the query data by calling the `aws_s3.query_export_to_s3` function.

After you complete the preceding preparation tasks, use the [aws\\_s3.query\\_export\\_to\\_s3 \(p. 1252\)](#) function to export query results to Amazon S3. For details about this process, see [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function \(p. 1249\)](#).

## Specifying the Amazon S3 file path to export to

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- Bucket name – A *bucket* is a container for Amazon S3 objects or files.

For more information on storing data with Amazon S3, see [Create a bucket](#) and [View an object](#) in the *Amazon Simple Storage Service User Guide*.

- File path – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on.

For example, a file path with an `exports` folder and a `query-1-export` file prefix is `/exports/query-1-export`.

- AWS Region (optional) – The AWS Region where the Amazon S3 bucket is located. If you don't specify an AWS Region value, then Aurora saves your files into Amazon S3 in the same AWS Region as the exporting DB cluster.

**Note**

Currently, the AWS Region must be the same as the region of the exporting DB cluster.

For a listing of AWS Region names and associated values, see [Regions and Availability Zones \(p. 11\)](#).

To hold the Amazon S3 file information about where the export is to be stored, you can use the [aws\\_commons.create\\_s3\\_uri \(p. 1254\)](#) function to create an `aws_commons._s3_uri_1` composite structure as follows.

```
psql=> SELECT aws_commons.create_s3_uri(
    'sample-bucket',
    'sample-filepath',
    'us-west-2'
) AS s3_uri_1 \gset
```

You later provide this `s3_uri_1` value as a parameter in the call to the [aws\\_s3.query\\_export\\_to\\_s3 \(p. 1252\)](#) function. For examples, see [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function \(p. 1249\)](#).

## Setting up access to an Amazon S3 bucket

To export data to Amazon S3, give your PostgreSQL DB cluster permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

### To give a PostgreSQL DB cluster access to Amazon S3 through an IAM role

1. Create an IAM policy.

This policy provides the bucket and object permissions that allow your PostgreSQL DB cluster to access Amazon S3.

As part of creating this policy, take the following steps:

- a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB cluster to an Amazon S3 bucket:

- `s3:PutObject`
- `s3:AbortMultipartUpload`

- b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is: `arn:aws:s3:::your-s3-bucket/*`

For more information on creating an IAM policy for Aurora PostgreSQL, see [Creating and using an IAM policy for IAM database access \(p. 1686\)](#). See also [Tutorial: Create and attach your first customer managed policy](#) in the *IAM User Guide*.

The following AWS CLI command creates an IAM policy named `rds-s3-export-policy` with these options. It grants access to a bucket named `your-s3-bucket`.

**Warning**

We recommend that you set up your database within a private VPC that has endpoint policies configured for accessing specific buckets. For more information, see [Using endpoint policies for Amazon S3](#) in the Amazon VPC User Guide.

We strongly recommend that you do not create a policy with all-resource access. This access can pose a threat for data security. If you create a policy that gives `S3:PutObject` access to all resources using `"Resource": "*"`, then a user with export privileges can export data to all buckets in your account. In addition, the user can export data to *any publicly writable bucket within your AWS Region*.

After you create the policy, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy --policy-name rds-s3-export-policy --policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "s3export",  
            "Action": [  
                "S3:PutObject"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:s3:::your-s3-bucket/*"  
            ]  
        }  
    ]  
}'
```

2. Create an IAM role.

You do this so Aurora PostgreSQL can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the [confused deputy problem](#).

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-export-role`.

### Example

For Linux, macOS, or Unix:

```
aws iam create-role \
--role-name rds-s3-export-role \
--assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111122223333",
                    "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
                }
            }
        ]
    }
}'
```

For Windows:

```
aws iam create-role ^
--role-name rds-s3-export-role ^
--assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111122223333",
                    "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
                }
            }
        ]
    }
}'
```

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named `rds-s3-export-role`. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

4. Add the IAM role to the DB cluster. You do so by using the AWS Management Console or AWS CLI, as described following.

## Console

### To add an IAM role for a PostgreSQL DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the PostgreSQL DB cluster name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance**.
4. Under **Feature**, choose **s3Export**.
5. Choose **Add role**.

## AWS CLI

### To add an IAM role for a PostgreSQL DB cluster using the CLI

- Use the following command to add the role to the PostgreSQL DB cluster named `my-db-cluster`. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use `s3Export` for the value of the `--feature-name` option.

#### Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-cluster \
    --db-cluster-identifier my-db-cluster \
    --feature-name s3Export \
    --role-arn your-role-arn \
    --region your-region
```

For Windows:

```
aws rds add-role-to-db-cluster ^
    --db-cluster-identifier my-db-cluster ^
    --feature-name s3Export ^
    --role-arn your-role-arn ^
    --region your-region
```

## Exporting query data using the `aws_s3.query_export_to_s3` function

Export your PostgreSQL data to Amazon S3 by calling the [aws\\_s3.query\\_export\\_to\\_s3](#) (p. 1252) function.

### Topics

- [Prerequisites](#) (p. 1250)
- [Calling aws\\_s3.query\\_export\\_to\\_s3](#) (p. 1250)
- [Exporting to a CSV file that uses a custom delimiter](#) (p. 1251)
- [Exporting to a binary file with encoding](#) (p. 1251)

## Prerequisites

Before you use the `aws_s3.query_export_to_s3` function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in [Overview of exporting data to Amazon S3 \(p. 1245\)](#).
- Determine where to export your data to Amazon S3 as described in [Specifying the Amazon S3 file path to export to \(p. 1245\)](#).
- Make sure that the DB cluster has export access to Amazon S3 as described in [Setting up access to an Amazon S3 bucket \(p. 1246\)](#).

The examples following use a database table called `sample_table`. These examples export the data into a bucket called `sample-bucket`. The example table and data are created with the following SQL statements in `psql`.

```
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid, name) VALUES (1, 'Monday'), (2, 'Tuesday'), (3, 'Wednesday');
```

## Calling `aws_s3.query_export_to_s3`

The following shows the basic ways of calling the [aws\\_s3.query\\_export\\_to\\_s3 \(p. 1252\)](#) function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the [aws\\_commons.create\\_s3\\_uri \(p. 1254\)](#) function to create the structure.

```
psql=> SELECT aws_commons.create_s3_uri(
    'sample-bucket',
    'sample-filepath',
    'us-west-2'
) AS s3_uri_1 \gset
```

Although the parameters vary for the following two `aws_s3.query_export_to_s3` function calls, the results are the same for these examples. All rows of the `sample_table` table are exported into a bucket called `sample-bucket`.

```
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1');
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1',
    options := 'format text');
```

The parameters are described as follows:

- '`SELECT * FROM sample_table`' – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.
- `: 's3_uri_1'` – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the structure by including the `aws_commons.create_s3_uri` function call inline within the `aws_s3.query_export_to_s3` function call as follows.

```
SELECT * from aws_s3.query_export_to_s3('select * from sample_table',
aws_commons.create_s3_uri('sample-bucket', 'sample-filepath', 'us-west-2')
```

```
);
```

- `options :='format text'` – The `options` parameter is an optional text string containing PostgreSQL `COPY` arguments. The copy process uses the arguments and format of the [PostgreSQL COPY command](#).

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.

```
s3-region:://bucket-name[/path-prefix]/file-prefix
```

Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```
s3-us-west-2://my-bucket/my-prefix
```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```
s3-us-west-2://my-bucket/my-prefix
s3-us-west-2://my-bucket/my-prefix_part2
s3-us-west-2://my-bucket/my-prefix_part3
```

For the full reference for this function and additional ways to call it, see [aws\\_s3.query\\_export\\_to\\_s3 \(p. 1252\)](#). For more about accessing files in Amazon S3, see [View an object in the Amazon Simple Storage Service User Guide](#).

## Exporting to a CSV file that uses a custom delimiter

The following example shows how to call the [aws\\_s3.query\\_export\\_to\\_s3 \(p. 1252\)](#) function to export data to a file that uses a custom delimiter. The example uses arguments of the [PostgreSQL COPY command](#) to specify the comma-separated value (CSV) format and a colon (:) delimiter.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
                                         options :='format csv, delimiter $$:$>');
```

## Exporting to a binary file with encoding

The following example shows how to call the [aws\\_s3.query\\_export\\_to\\_s3 \(p. 1252\)](#) function to export data to a binary file that has Windows-1253 encoding.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
                                         options :='format binary, encoding WIN1253');
```

## Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, the security group must have a rule that allows the DB instance to send TCP traffic to port 443 and to any IPv4 addresses (0.0.0.0/0). For more information, see [Provide access to the DB cluster in the VPC by creating a security group \(p. 90\)](#).

See also the following for recommendations:

- [Troubleshooting Amazon Aurora identity and access \(p. 1710\)](#)
- [Troubleshooting Amazon S3 in the Amazon Simple Storage Service User Guide](#)
- [Troubleshooting Amazon S3 and IAM in the IAM User Guide](#)

## Function reference

### Functions

- [aws\\_s3.query\\_export\\_to\\_s3 \(p. 1252\)](#)
- [aws\\_commons.create\\_s3\\_uri \(p. 1254\)](#)

### [aws\\_s3.query\\_export\\_to\\_s3](#)

Exports a PostgreSQL query result to an Amazon S3 bucket. The `aws_s3` extension provides the `aws_s3.query_export_to_s3` function.

The two required parameters are `query` and `s3_info`. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called `options` provides for defining various export parameters. For examples of using the `aws_s3.query_export_to_s3` function, see [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function \(p. 1249\)](#).

#### Syntax

```
aws_s3.query_export_to_s3(  
    query text,  
    s3_info aws_commons._s3_uri_1,  
    options text  
)
```

#### Input parameters

##### `query`

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

##### `s3_info`

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket to contain the file.
- `file_path` – The Amazon S3 file name and path.
- `region` – The AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see [Regions and Availability Zones \(p. 11\)](#).

Currently, this value must be the same AWS Region as that of the exporting DB cluster . The default is the AWS Region of the exporting DB cluster .

To create an `aws_commons._s3_uri_1` composite structure, see the [aws\\_commons.create\\_s3\\_uri \(p. 1254\)](#) function.

##### `options`

An optional text string containing arguments for the PostgreSQL `COPY` command. These arguments specify how the data is to be copied when exported. For more details, see the [PostgreSQL COPY documentation](#).

## Alternate input parameters

To help with testing, you can use an expanded set of parameters instead of the `s3_info` parameter. Following are additional syntax variations for the `aws_s3.query_export_to_s3` function.

Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters.

```
aws_s3.query_export_to_s3(  
    query text,  
    bucket text,  
    file_path text,  
    region text,  
    options text  
)
```

### *query*

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

### *bucket*

A required text string containing the name of the Amazon S3 bucket that contains the file.

### *file\_path*

A required text string containing the Amazon S3 file name including the path of the file.

### *region*

An optional text string containing the AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see [Regions and Availability Zones \(p. 11\)](#).

Currently, this value must be the same AWS Region as that of the exporting DB cluster . The default is the AWS Region of the exporting DB cluster .

### *options*

An optional text string containing arguments for the PostgreSQL `COPY` command. These arguments specify how the data is to be copied when exported. For more details, see the [PostgreSQL COPY documentation](#).

## Output parameters

```
aws_s3.query_export_to_s3(  
    OUT rows_uploaded bigint,  
    OUT files_uploaded bigint,  
    OUT bytes_uploaded bigint  
)
```

### *rows\_uploaded*

The number of table rows that were successfully uploaded to Amazon S3 for the given query.

### *files\_uploaded*

The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has `_partXX` appended to the name. The `XX` represents 2, then 3, and so on as needed.

*bytes\_uploaded*

The total number of bytes uploaded to Amazon S3.

## Examples

```
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-
bucket', 'samplefilepath');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-
bucket', 'samplefilepath','us-west-2');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-
bucket', 'samplefilepath','us-west-2','format text');
```

## aws\_commons.create\_s3\_uri

Creates an `aws_commons.s3_uri_1` structure to hold Amazon S3 file information. You use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the [aws\\_s3.query\\_export\\_to\\_s3 \(p. 1252\)](#) function. For an example of using the `aws_commons.create_s3_uri` function, see [Specifying the Amazon S3 file path to export to \(p. 1245\)](#).

### Syntax

```
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```

### Input parameters

*bucket*

A required text string containing the Amazon S3 bucket name for the file.

*file\_path*

A required text string containing the Amazon S3 file name including the path of the file.

*region*

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see [Regions and Availability Zones \(p. 11\)](#).

## Invoking an AWS Lambda function from an Aurora PostgreSQL DB cluster

AWS Lambda is an event-driven compute service that lets you run code without provisioning or managing servers. It's available for use with many AWS services, including Aurora PostgreSQL. For example, you can use Lambda functions to process event notifications from a database, or to load data from files whenever a new file is uploaded to Amazon S3. To learn more about Lambda, see [What is AWS Lambda?](#) in the *AWS Lambda Developer Guide*.

**Note**

Invoking AWS Lambda functions is supported in Aurora PostgreSQL 11.9 and higher.

Setting up Aurora PostgreSQL to work with Lambda functions is a multi-step process involving AWS Lambda, IAM, your VPC, and your Aurora PostgreSQL DB cluster. Following, you can find summaries of the necessary steps.

For more information about Lambda functions, see [Getting started with Lambda](#) and [AWS Lambda foundations](#) in the *AWS Lambda Developer Guide*.

#### Topics

- [Step 1: Configure your Aurora PostgreSQL DB cluster for outbound connections to AWS Lambda \(p. 1255\)](#)
- [Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and AWS Lambda \(p. 1255\)](#)
- [Step 3: Install the aws\\_lambda extension for an Aurora PostgreSQL DB cluster \(p. 1257\)](#)
- [Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster \(Optional\) \(p. 1257\)](#)
- [Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster \(p. 1258\)](#)
- [Step 6: Grant other users permission to invoke Lambda functions \(p. 1259\)](#)
- [Examples: Invoking Lambda functions from your Aurora PostgreSQL DB cluster \(p. 1259\)](#)
- [Lambda function error messages \(p. 1261\)](#)
- [AWS Lambda function reference \(p. 1262\)](#)

## Step 1: Configure your Aurora PostgreSQL DB cluster for outbound connections to AWS Lambda

Lambda functions always run inside an Amazon VPC that's owned by the AWS Lambda service. Lambda applies network access and security rules to this VPC and it maintains and monitors the VPC automatically. Your Aurora PostgreSQL DB cluster sends network traffic to the Lambda service's VPC. How you configure this depends on whether your Aurora DB cluster's primary DB instance is public or private.

- **Public Aurora PostgreSQL DB cluster** – A DB cluster's primary DB instance is public if it's located in a public subnet on your VPC, and if the instance's "PubliclyAccessible" property is `true`. To find the value of this property, you can use the [describe-db-instances](#) AWS CLI command. Or, you can use the AWS Management Console to open the **Connectivity & security** tab and check that **Publicly accessible** is `Yes`. To verify that the instance is in the public subnet of your VPC, you can use the AWS Management Console or the AWS CLI.

To set up access to Lambda, you use the AWS Management Console or the AWS CLI to create an outbound rule on your VPC's security group. The outbound rule specifies that TCP can use port 443 to send packets to any IPv4 addresses (0.0.0.0/0).

- **Private Aurora PostgreSQL DB cluster** – In this case, the instance's "PubliclyAccessible" property is `false` or it's in a private subnet. To allow the instance to work with Lambda, you can use a Network Address Translation (NAT) gateway. For more information, see [NAT gateways](#). Or, you can configure your VPC with a VPC endpoint for Lambda. For more information, see [VPC endpoints](#) in the *Amazon VPC User Guide*. The endpoint responds to calls made by your Aurora PostgreSQL DB cluster to your Lambda functions.

Your VPC can now interact with the AWS Lambda VPC at the network level. Next, you configure the permissions using IAM.

## Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and AWS Lambda

Invoking Lambda functions from your Aurora PostgreSQL DB cluster requires certain privileges. To configure the necessary privileges, we recommend that you create an IAM policy that allows invoking Lambda functions, assign that policy to a role, and then apply the role to your DB cluster. This approach gives the DB cluster privileges to invoke the specified Lambda function on your behalf. The following steps show you how to do this using the AWS CLI.

## To configure IAM permissions for using your cluster with Lambda

1. Use the [create-policy](#) AWS CLI command to create an IAM policy that allows your Aurora PostgreSQL DB cluster to invoke the specified Lambda function. (The statement ID (Sid) is an optional description for your policy statement and has no effect on usage.) This policy gives your Aurora DB cluster the minimum permissions needed to invoke the specified Lambda function.

```
aws iam create-policy --policy-name rds-lambda-policy --policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowAccessToExampleFunction",  
            "Effect": "Allow",  
            "Action": "lambda:InvokeFunction",  
            "Resource": "arn:aws:lambda:aws-region:444455556666:function:my-function"  
        }  
    ]  
}'
```

Alternatively, you can use the predefined `AWSLambdaRole` policy that allows you to invoke any of your Lambda functions. For more information, see [Identity-based IAM policies for Lambda](#)

2. Use the [create-role](#) AWS CLI command to create an IAM role that the policy can assume at runtime.

```
aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "rds.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}'
```

3. Apply the policy to the role by using the [attach-role-policy](#) AWS CLI command.

```
aws iam attach-role-policy \  
    --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy \  
    --role-name rds-lambda-role --region aws-region
```

4. Apply the role to your Aurora PostgreSQL DB cluster by using the [add-role-to-db-cluster](#) AWS CLI command. This last step allows your DB cluster's database users to invoke Lambda functions.

```
aws rds add-role-to-db-cluster \  
    --db-cluster-identifier my-cluster-name \  
    --feature-name Lambda \  
    --role-arn arn:aws:iam::444455556666:role/rds-lambda-role \  
    --region aws-region
```

With the VPC and the IAM configurations complete, you can now install the `aws_lambda` extension. (Note that you can install the extension at any time, but until you set up the correct VPC support and IAM privileges, the `aws_lambda` extension adds nothing to your Aurora PostgreSQL DB cluster's capabilities.)

## Step 3: Install the aws\_lambda extension for an Aurora PostgreSQL DB cluster

To use AWS Lambda with your Aurora PostgreSQL DB cluster, the `aws_lambda` PostgreSQL extension to your Aurora PostgreSQL. This extension provides your Aurora PostgreSQL DB cluster with the ability to call Lambda functions from PostgreSQL.

### To install the `aws_lambda` extension in your Aurora PostgreSQL DB cluster

Use the PostgreSQL `psql` command-line or the pgAdmin tool to connect to your Aurora PostgreSQL DB cluster .

1. Connect to your Aurora PostgreSQL DB cluster instance as a user with `rds_superuser` privileges. The default `postgres` user is shown in the example.

```
psql -h cluster-instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Install the `aws_lambda` extension. The `aws_commons` extension is also required. It provides helper functions to `aws_lambda` and many other Aurora extensions for PostgreSQL. If it's not already on your Aurora PostgreSQLDB cluster , it's installed with `aws_lambda` as shown following.

```
CREATE EXTENSION IF NOT EXISTS aws_lambda CASCADE;
NOTICE:  installing required extension "aws_commons"
CREATE EXTENSION
```

The `aws_lambda` extension is installed in your Aurora PostgreSQL DB cluster's primary DB instance. You can now create convenience structures for invoking your Lambda functions.

## Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster (Optional)

You can use the helper functions in the `aws_commons` extension to prepare entities that you can more easily invoke from PostgreSQL. To do this, you need to have the following information about your Lambda functions:

- **Function name** – The name, Amazon Resource Name (ARN), version, or alias of the Lambda function. The IAM policy created in [Step 2: Configure IAM for your cluster and Lambda \(p. 1255\)](#) requires the ARN, so we recommend that you use your function's ARN.
- **AWS Region** – (Optional) The AWS Region where the Lambda function is located if it's not in the same Region as your Aurora PostgreSQL DB cluster.

To hold the Lambda function name information, you use the `aws_commons.create_lambda_function_arn (p. 1264)` function. This helper function creates an `aws_commons._lambda_function_arn_1` composite structure with the details needed by the `invoke` function. Following, you can find three alternative approaches to setting up this composite structure.

```
SELECT aws_commons.create_lambda_function_arn(
    'my-function',
    'aws-region'
) AS aws_lambda_arn_1 \gset
```

```
SELECT aws_commons.create_lambda_function_arn(
    '111122223333:function:my-function',
```

```
'aws-region'  
) AS lambda_partial_arn_1 \gset
```

```
SELECT aws_commons.create_lambda_function_arn(  
    'arn:aws:lambda:aws-region:111122223333:function:my-function'  
) AS lambda_arn_1 \gset
```

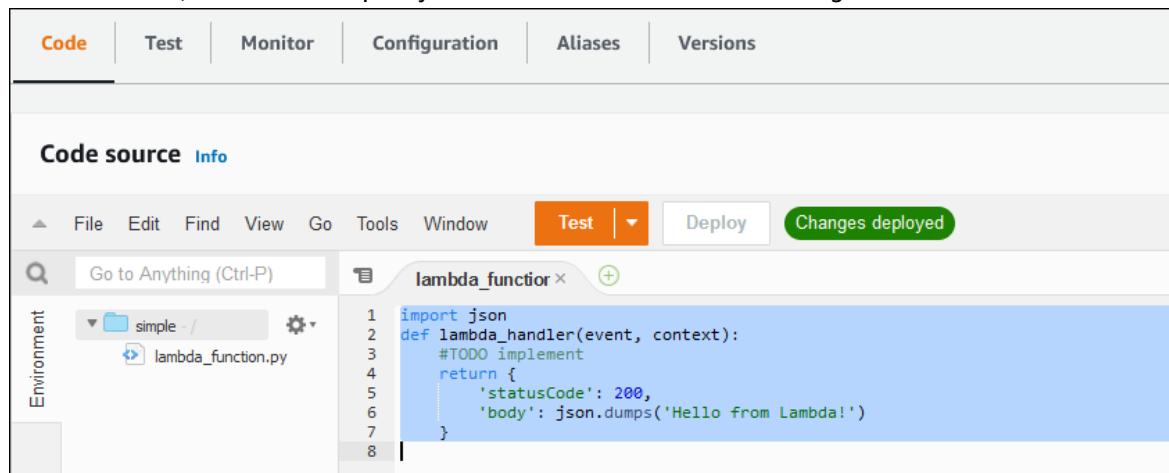

Any of these values can be used in calls to the [aws\\_lambda.invoke \(p. 1262\)](#) function. For examples, see [Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster \(p. 1258\)](#).

## Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster

The `aws_lambda.invoke` function behaves synchronously or asynchronously, depending on the `invocation_type`. The two alternatives for this parameter are `RequestResponse` (the default) and `Event`, as follows.

- **RequestResponse** – This invocation type is *synchronous*. It's the default behavior when the call is made without specifying an invocation type. The response payload includes the results of the `aws_lambda.invoke` function. Use this invocation type when your workflow requires receiving results from the Lambda function before proceeding.
- **Event** – This invocation type is *asynchronous*. The response doesn't include a payload containing results. Use this invocation type when your workflow doesn't need a result from the Lambda function to continue processing.

As a simple test of your setup, you can connect to your DB instance using `psql` and invoke an example function from the command line. Suppose that you have one of the basic functions set up on your Lambda service, such as the simple Python function shown in the following screenshot.

### To invoke an example function

1. Connect to your primary DB instance using `psql` or pgAdmin.

```
psql -h cluster.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Invoke the function using its ARN.

```
SELECT * from  
aws_lambda.invoke(aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-
```

```
region:444455556666:function:simple', 'us-west-1'), '{"body": "Hello from Postgres!"}':json );
```

The response looks as follows.

status_code     log_result	payload	executed_version
-----+-----+-----	-----+-----+	-----+-----+
200   {"statusCode": 200, "body": "\"Hello from Lambda!\""}   \$LATEST		
(1 row)		

If your invocation attempt doesn't succeed, see [Lambda function error messages \(p. 1261\)](#).

## Step 6: Grant other users permission to invoke Lambda functions

At this point in the procedures, only you as `rds_superuser` can invoke your Lambda functions. To allow other users to invoke any functions that you create, you need to grant them permission.

### To grant others permission to invoke Lambda functions

1. Connect to your primary DB instance using `psql` or `pgAdmin`.

```
psql -h cluster.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Run the following SQL commands:

```
postgres=> GRANT USAGE ON SCHEMA aws_lambda TO db_username;
GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA aws_lambda TO db_username;
```

## Examples: Invoking Lambda functions from your Aurora PostgreSQL DB cluster

Following, you can find several examples of calling the `aws_lambda.invoke` (p. 1262) function. Most all the examples use the composite structure `aws_lambda_arn_1` that you create in [Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster \(Optional\) \(p. 1257\)](#) to simplify passing the function details. For an example of asynchronous invocation, see [Example: Asynchronous \(Event\) invocation of Lambda functions \(p. 1260\)](#). All the other examples listed use synchronous invocation.

To learn more about Lambda invocation types, see [Invoking Lambda functions](#) in the *AWS Lambda Developer Guide*. For more information about `aws_lambda_arn_1`, see [aws\\_commons.create\\_lambda\\_function\\_arn \(p. 1264\)](#).

### Examples list

- [Example: Synchronous \(RequestResponse\) invocation of Lambda functions \(p. 1260\)](#)
- [Example: Asynchronous \(Event\) invocation of Lambda functions \(p. 1260\)](#)
- [Example: Capturing the Lambda execution log in a function response \(p. 1260\)](#)
- [Example: Including client context in a Lambda function \(p. 1261\)](#)
- [Example: Invoking a specific version of a Lambda function \(p. 1261\)](#)

## Example: Synchronous (RequestResponse) invocation of Lambda functions

Following are two examples of a synchronous Lambda function invocation. The results of these `aws_lambda.invoke` function calls are the same.

```
SELECT * FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"'}::json);
```

```
SELECT * FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"'}::json, 'RequestResponse');
```

The parameters are described as follows:

- `:'aws_lambda_arn_1'` – This parameter identifies the composite structure created in [Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster \(Optional\) \(p. 1257\)](#), with the `aws_commons.create_lambda_function_arn` helper function. You can also create this structure inline within your `aws_lambda.invoke` call as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function', 'aws-region'), '{"body": "Hello from Postgres!"'}::json);
```

- `'{"body": "Hello from PostgreSQL!"'}::json` – The JSON payload to pass to the Lambda function.
- `'RequestResponse'` – The Lambda invocation type.

## Example: Asynchronous (Event) invocation of Lambda functions

Following is an example of an asynchronous Lambda function invocation. The `Event` invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the `Event` invocation type in certain workflows that don't depend on the results of the Lambda function.

```
SELECT * FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"'}::json, 'Event');
```

## Example: Capturing the Lambda execution log in a function response

You can include the last 4 KB of the execution log in the function response by using the `log_type` parameter in your `aws_lambda.invoke` function call. By default, this parameter is set to `None`, but you can specify `Tail` to capture the results of the Lambda execution log in the response, as shown following.

```
SELECT *, select convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"'}::json, 'RequestResponse', 'Tail');
```

Set the [aws\\_lambda.invoke \(p. 1262\)](#) function's `log_type` parameter to `Tail` to include the execution log in the response. The default value for the `log_type` parameter is `None`.

The `log_result` that's returned is a `base64` encoded string. You can decode the contents using a combination of the `decode` and `convert_from` PostgreSQL functions.

For more information about `log_type`, see [aws\\_lambda.invoke \(p. 1262\)](#).

## Example: Including client context in a Lambda function

The `aws_lambda.invoke` function has a `context` parameter that you can use to pass information separate from the payload, as shown following.

```
SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the [aws\\_lambda.invoke \(p. 1262\)](#) function's `context` parameter.

For more information about the `context` parameter, see the [aws\\_lambda.invoke \(p. 1262\)](#) reference.

## Example: Invoking a specific version of a Lambda function

You can specify a particular version of a Lambda function by including the `qualifier` parameter with the `aws_lambda.invoke` call. Following, you can find an example that does this using '`custom_version`' as an alias for the version.

```
SELECT * FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse', 'None', NULL, 'custom_version');
```

You can also supply a Lambda function qualifier with the function name details instead, as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function:custom_version', 'us-west-2'), '{"body": "Hello from Postgres!"}':json);
```

For more information about `qualifier` and other parameters, see the [aws\\_lambda.invoke \(p. 1262\)](#) reference.

## Lambda function error messages

In the following list you can find information about error messages, with possible causes and solutions.

- **VPC configuration issues**

VPC configuration issues can raise the following error messages when trying to connect:

```
ERROR: invoke API failed
DETAIL: AWS Lambda client returned 'Unable to connect to endpoint'.
CONTEXT: SQL function "invoke" statement 1
```

A common cause for this error is improperly configured VPC security group. Make sure you have an outbound rule for TCP open on port 443 of your VPC security group so that your VPC can connect to the Lambda VPC.

- **Lack of permissions needed to invoke Lambda functions**

If you see either of the following error messages, the user (role) invoking the function doesn't have proper permissions.

```
ERROR: permission denied for schema aws_lambda
```

```
ERROR: permission denied for function invoke
```

A user (role) must be given specific grants to invoke Lambda functions. For more information, see [Step 6: Grant other users permission to invoke Lambda functions \(p. 1259\)](#).

- **Improper handling of errors in your Lambda functions**

If a Lambda function throws an exception during request processing, `aws_lambda.invoke` fails with a PostgreSQL error such as the following.

```
SELECT * FROM aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}');  
ERROR: lambda invocation failed  
DETAIL: "arn:aws:lambda:us-west-2:555555555555:function:my-function" returned error "Unhandled", details: "<Error details string>".
```

Be sure to handle errors in your Lambda functions or in your PostgreSQL application.

## AWS Lambda function reference

Following is the reference for the functions to use for invoking Lambda functions with Aurora PostgreSQL .

### Functions

- [aws\\_lambda.invoke \(p. 1262\)](#)
- [aws\\_commons.create\\_lambda\\_function\\_arn \(p. 1264\)](#)

### aws\_lambda.invoke

Runs a Lambda function for an Aurora PostgreSQL DB cluster .

For more details about invoking Lambda functions, see also [Invoke in the AWS Lambda Developer Guide](#).

#### Syntax

##### JSON

```
aws_lambda.invoke(  
    IN function_name TEXT,  
    IN payload JSON,  
    IN region TEXT DEFAULT NULL,  
    IN invocation_type TEXT DEFAULT 'RequestResponse',  
    IN log_type TEXT DEFAULT 'None',  
    IN context JSON DEFAULT NULL,  
    IN qualifier VARCHAR(128) DEFAULT NULL,  
    OUT status_code INT,  
    OUT payload JSON,  
    OUT executed_version TEXT,  
    OUT log_result TEXT)
```

```
aws_lambda.invoke(  
    IN function_name aws_commons._lambda_function_arn_1,  
    IN payload JSON,  
    IN invocation_type TEXT DEFAULT 'RequestResponse',  
    IN log_type TEXT DEFAULT 'None',  
    IN context JSON DEFAULT NULL,  
    IN qualifier VARCHAR(128) DEFAULT NULL,  
    OUT status_code INT,  
    OUT payload JSON,
```

```
    OUT executed_version TEXT,  
    OUT log_result TEXT)
```

## JSONB

```
aws_lambda.invoke(  
    IN function_name TEXT,  
    IN payload JSONB,  
    IN region TEXT DEFAULT NULL,  
    IN invocation_type TEXT DEFAULT 'RequestResponse',  
    IN log_type TEXT DEFAULT 'None',  
    IN context JSONB DEFAULT NULL,  
    IN qualifier VARCHAR(128) DEFAULT NULL,  
    OUT status_code INT,  
    OUT payload JSONB,  
    OUT executed_version TEXT,  
    OUT log_result TEXT)
```

```
aws_lambda.invoke(  
    IN function_name aws_commons._lambda_function_arn_1,  
    IN payload JSONB,  
    IN invocation_type TEXT DEFAULT 'RequestResponse',  
    IN log_type TEXT DEFAULT 'None',  
    IN context JSONB DEFAULT NULL,  
    IN qualifier VARCHAR(128) DEFAULT NULL,  
    OUT status_code INT,  
    OUT payload JSONB,  
    OUT executed_version TEXT,  
    OUT log_result TEXT  
)
```

## Input parameters

### *function\_name*

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see [Lambda function name formats](#) in the *AWS Lambda Developer Guide*.

### *payload*

The input for the Lambda function. The format can be JSON or JSONB. For more information, see [JSON Types](#) in the PostgreSQL documentation.

### *region*

(Optional) The Lambda Region for the function. By default, Aurora resolves the AWS Region from the full ARN in the *function\_name* or it uses the Aurora PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the *function\_name* ARN, an error is raised.

### *invocation\_type*

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

- RequestResponse – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the RequestResponse invocation type when your workflow depends on receiving the Lambda function result immediately.
- Event – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the Event invocation type when you don't need results of the Lambda function before your workflow moves on.

- `DryRun` – This type of invocation tests access without running the Lambda function.

*log\_type*

The type of Lambda log to return in the `log_result` output parameter. The value is case-sensitive. Possible values include the following:

- `Tail` – The returned `log_result` output parameter will include the last 4 KB of the execution log.
- `None` – No Lambda log information is returned.

*context*

Client context in JSON or JSONB format. Fields to use include `custom` and `env`.

*qualifier*

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the `function_name` ARN, an error is raised.

## Output parameters

*status\_code*

An HTTP status response code. For more information, see [Lambda Invoke response elements](#) in the *AWS Lambda Developer Guide*.

*payload*

The information returned from the Lambda function that ran. The format is in JSON or JSONB.

*executed\_version*

The version of the Lambda function that ran.

*log\_result*

The execution log information returned if the `log_type` value is `Tail` when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.

## [aws\\_commons.create\\_lambda\\_function\\_arn](#)

Creates an `aws_commons._lambda_function_arn_1` structure to hold Lambda function name information. You can use the results of the `aws_commons.create_lambda_function_arn` function in the `function_name` parameter of the `aws_lambda.invoke` ([p. 1262](#)) function.

### Syntax

```
aws_commons.create_lambda_function_arn(  
    function_name TEXT,  
    region TEXT DEFAULT NULL  
)  
RETURNS aws_commons._lambda_function_arn_1
```

## Input parameters

*function\_name*

A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.

*region*

An optional text string containing the AWS Region that the Lambda function is in. For a listing of Region names and associated values, see [Regions and Availability Zones \(p. 11\)](#).

# Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs

You can configure your Aurora PostgreSQL DB cluster to export log data to Amazon CloudWatch Logs on a regular basis. When you do so, events from your Aurora PostgreSQL DB cluster's PostgreSQL log are automatically *published* to Amazon CloudWatch, as Amazon CloudWatch Logs. In CloudWatch, you can find the exported log data in a *Log group* for your Aurora PostgreSQL DB cluster. The log group contains one or more *log streams* that contain the events from the PostgreSQL log from each instance in the cluster.

Publishing the logs to CloudWatch Logs allows you to keep your cluster's PostgreSQL log records in highly durable storage. With the log data available in CloudWatch Logs, you can evaluate and improve your cluster's operations. You can also use CloudWatch to create alarms and view metrics. To learn more, see [Monitoring log events in Amazon CloudWatch \(p. 1268\)](#).

## Note

Publishing your PostgreSQL logs to CloudWatch Logs consumes storage, and you incur charges for that storage. Be sure to delete any CloudWatch Logs that you no longer need.

Turning the export log option off for an existing Aurora PostgreSQL DB cluster doesn't affect any data that's already held in CloudWatch Logs. Existing logs remain available in CloudWatch Logs based on your log retention settings. To learn more about CloudWatch Logs, see [What is Amazon CloudWatch Logs?](#)

Aurora PostgreSQL supports publishing logs to CloudWatch Logs for the following versions.

- 14.3 and higher 14 versions
- 13.3 and higher 13 versions
- 12.8 and higher 12 versions
- 11.12 and higher 11 versions

## Turning on the option to publish logs to Amazon CloudWatch

To publish your Aurora PostgreSQL DB cluster's PostgreSQL log to CloudWatch Logs, choose the **Log export** option for the cluster. You can choose the Log export setting when you create your Aurora PostgreSQL DB cluster. Or, you can modify the cluster later on. When you modify an existing cluster, its PostgreSQL logs from each instance are published to CloudWatch cluster from that point on. For Aurora PostgreSQL, the PostgreSQL log (`postgresql.log`) is the only log that gets published to Amazon CloudWatch.

You can use the AWS Management Console, the AWS CLI, or the RDS API to turn on the Log export feature for your Aurora PostgreSQL DB cluster.

### Console

You choose the Log exports option to start publishing the PostgreSQL logs from your Aurora PostgreSQL DB cluster to CloudWatch Logs.

#### To turn on the Log export feature from the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora PostgreSQL DB cluster whose log data you want to publish to CloudWatch Logs.
4. Choose **Modify**.
5. In the **Log exports** section, choose **PostgreSQL log**.

6. Choose **Continue**, and then choose **Modify cluster** on the summary page.

## AWS CLI

You can turn on the log export option to start publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs with the AWS CLI. To do so, run the [modify-db-cluster](#) AWS CLI command with the following options:

- **--db-cluster-identifier**—The DB cluster identifier.
- **--cloudwatch-logs-export-configuration**—The configuration setting for the log types to be set for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora PostgreSQL logs by running one of the following AWS CLI commands:

- [create-db-cluster](#)
- [restore-db-cluster-from-s3](#)
- [restore-db-cluster-from-snapshot](#)
- [restore-db-cluster-to-point-in-time](#)

Run one of these AWS CLI commands with the following options:

- **--db-cluster-identifier**—The DB cluster identifier.
- **--engine**—The database engine.
- **--enable-cloudwatch-logs-exports**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other options might be required depending on the AWS CLI command that you run.

## Example

The following command creates an Aurora PostgreSQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
    --db-cluster-identifier my-db-cluster \
    --engine aurora-postgresql \
    --enable-cloudwatch-logs-exports postgresql
```

For Windows:

```
aws rds create-db-cluster ^
    --db-cluster-identifier my-db-cluster ^
    --engine aurora-postgresql ^
    --enable-cloudwatch-logs-exports postgresql
```

## Example

The following command modifies an existing Aurora PostgreSQL DB cluster to publish log files to CloudWatch Logs. The **--cloudwatch-logs-export-configuration** value is a JSON object. The key for this object is `EnableLogTypes`, and its value is `postgresql`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
--db-cluster-identifier my-db-cluster \
--cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql"]}'
```

For Windows:

```
aws rds modify-db-cluster ^
--db-cluster-identifier my-db-cluster ^
--cloudwatch-logs-export-configuration '{\"EnableLogTypes\":[\"postgresql\"]}'
```

**Note**

When using the Windows command prompt, make sure to escape double quotation marks ("") in JSON code by prefixing them with a backslash (\).

**Example**

The following example modifies an existing Aurora PostgreSQL DB cluster to disable publishing log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is DisableLogTypes, and its value is postgresql.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
--db-cluster-identifier mydbinstance \
--cloudwatch-logs-export-configuration '{"DisableLogTypes":["postgresql"]}'
```

For Windows:

```
aws rds modify-db-cluster ^
--db-cluster-identifier mydbinstance ^
--cloudwatch-logs-export-configuration "{\"DisableLogTypes\":[\"postgresql\"]}"
```

**Note**

When using the Windows command prompt, you must escape double quotes ("") in JSON code by prefixing them with a backslash (\).

[RDS API](#)

You can turn on the log export option to start publishing Aurora PostgreSQL logs with the RDS API. To do so, run the [ModifyDBCluster](#) operation with the following options:

- **DBClusterIdentifier** – The DB cluster identifier.
- **CloudwatchLogsExportConfiguration** – The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora PostgreSQL logs with the RDS API by running one of the following RDS API operations:

- [CreateDBCluster](#)
- [RestoreDBClusterFromS3](#)
- [RestoreDBClusterFromSnapshot](#)
- [RestoreDBClusterToPointInTime](#)

Run the RDS API action with the following parameters:

- `DBClusterIdentifier`—The DB cluster identifier.
- `Engine`—The database engine.
- `EnableCloudwatchLogsExports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other parameters might be required depending on the AWS CLI command that you run.

## Monitoring log events in Amazon CloudWatch

With Aurora PostgreSQL log events published and available as Amazon CloudWatch Logs, you can view and monitor events using Amazon CloudWatch. For more information about monitoring, see [View log data sent to CloudWatch Logs](#).

When you turn on Log exports, a new log group is automatically created using the prefix `/aws/rds/cluster/` with the name of your Aurora PostgreSQL and the log type, as in the following pattern.

```
/aws/rds/cluster/your-cluster-name/postgresql
```

As an example, suppose that an Aurora PostgreSQL DB cluster named `docs-lab-apg-small` exports its log to Amazon CloudWatch Logs. Its log group name in Amazon CloudWatch is shown following.

```
/aws/rds/cluster/docs-lab-apg-small/postgresql
```

If a log group with the specified name exists, Aurora uses that log group to export log data for the Aurora DB cluster. Each DB instance in the Aurora PostgreSQL DB cluster uploads its PostgreSQL log to the log group as a distinct log stream. You can examine the log group and its log streams using the various graphical and analytical tools available in Amazon CloudWatch.

For example, you can search for information within the log events from your Aurora PostgreSQL DB cluster, and filter events by using the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API. For more information, [Searching and filtering log data](#) in the *Amazon CloudWatch Logs User Guide*.

By default, new log groups are created using **Never expire** for their retention period. You can use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API to change the log retention period. To learn more, see [Change log data retention in CloudWatch Logs](#) in the *Amazon CloudWatch Logs User Guide*.

### Tip

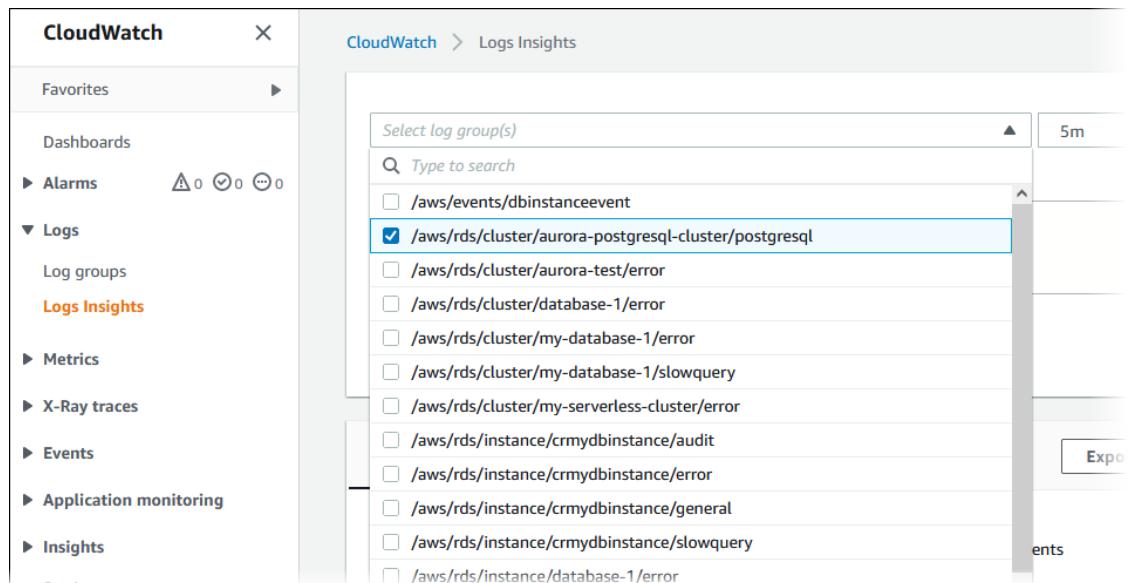

You can use automated configuration, such as AWS CloudFormation, to create log groups with predefined log retention periods, metric filters, and access permissions.

## Analyzing PostgreSQL logs using CloudWatch Logs Insights

With the PostgreSQL logs from your Aurora PostgreSQL DB cluster published as CloudWatch Logs, you can use CloudWatch Logs Insights to interactively search and analyze your log data in Amazon CloudWatch Logs. CloudWatch Logs Insights includes a query language, sample queries, and other tools for analyzing your log data so that you can identify potential issues and verify fixes. To learn more, see [Analyzing log data with CloudWatch Logs Insights](#) in the *Amazon CloudWatch Logs User Guide*. Amazon CloudWatch Logs

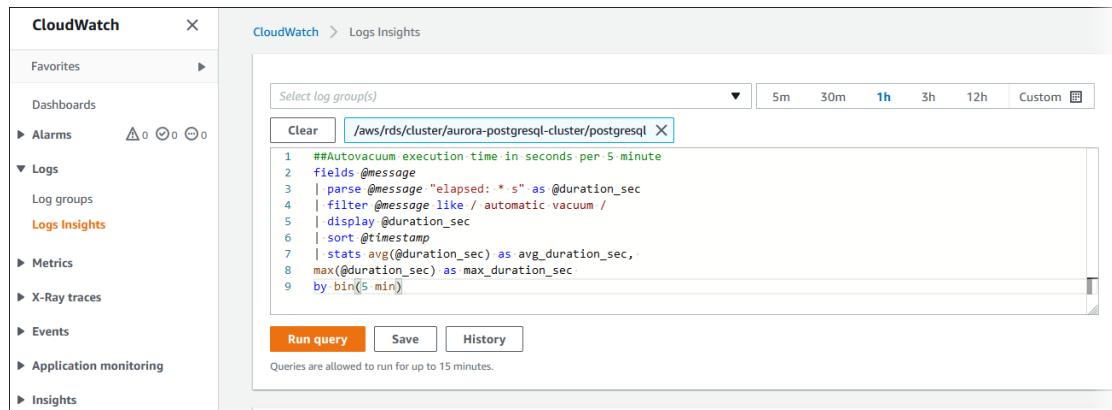

### To analyze PostgreSQL logs with CloudWatch Logs Insights

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the navigation pane, open **Logs** and choose **Log insights**.
3. In **Select log group(s)**, select the log group for your Aurora PostgreSQL DB cluster.

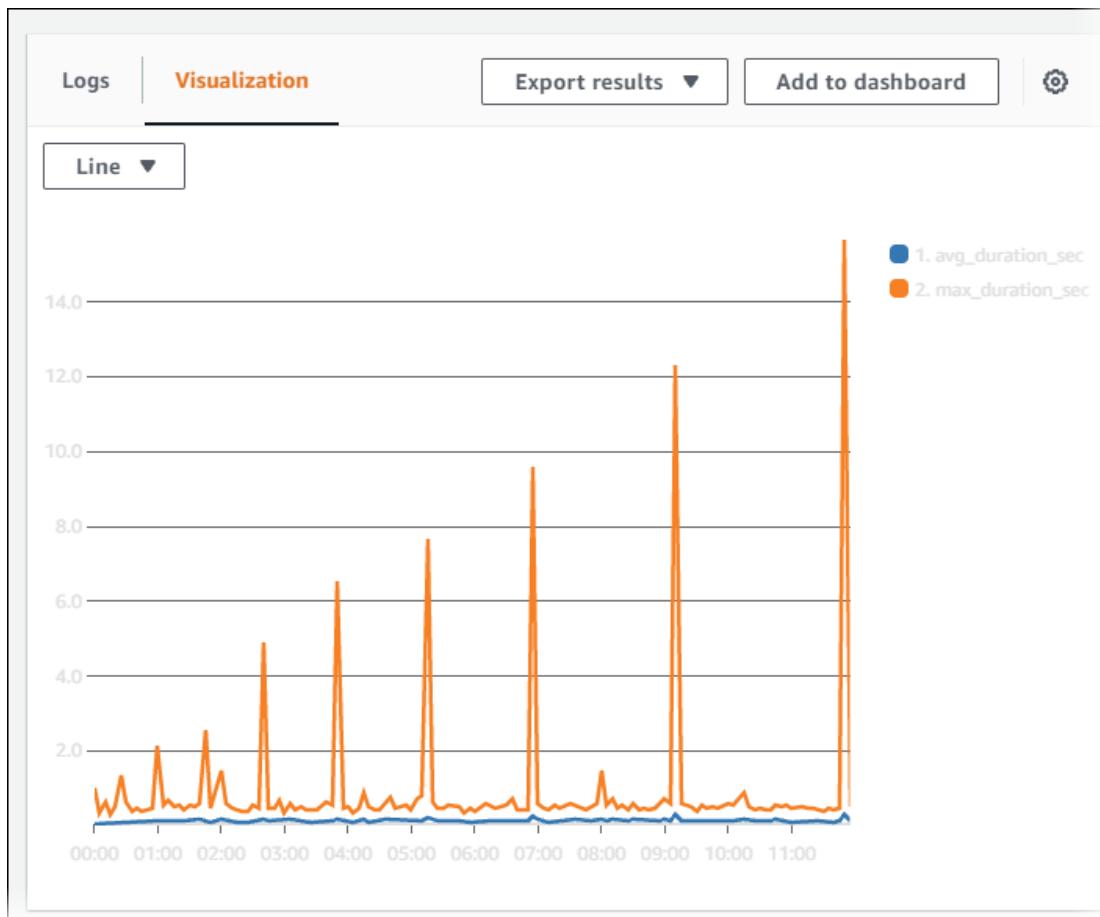

4. In the query editor, delete the query that is currently shown, enter the following, and then choose **Run query**.

```
##Autovacuum execution time in seconds per 5 minute
fields @message
| parse @message "elapsed: * s" as @duration_sec
| filter @message like / automatic vacuum /
| display @duration_sec
| sort @timestamp
| stats avg(@duration_sec) as avg_duration_sec,
max(@duration_sec) as max_duration_sec
by bin(5 min)
```

5. Choose the **Visualization** tab.

6. Choose **Add to dashboard**.
7. In **Select a dashboard**, either select a dashboard or enter a name to create a new dashboard.
8. In **Widget type**, choose a widget type for your visualization.

**Add to dashboard** X

Select a dashboard  
Select an existing dashboard or create a new one.  
 X

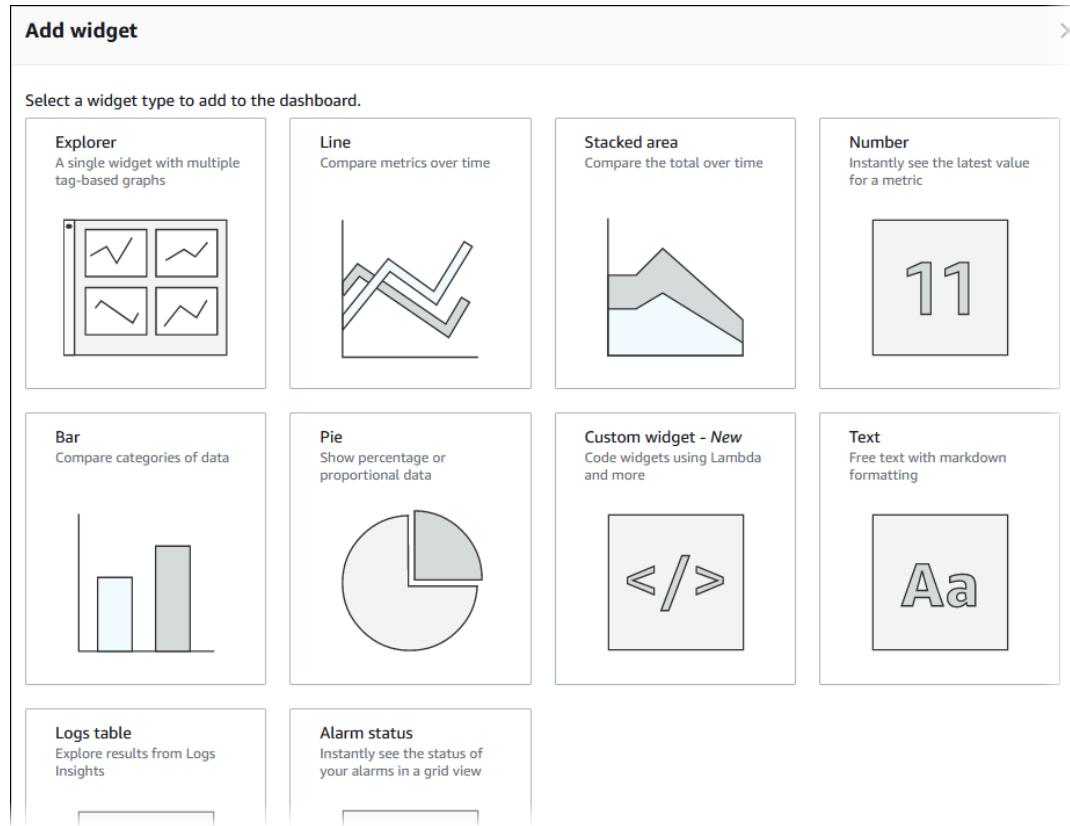

Widget type  
Select a widget type to add to the dashboard.

Customize widget title  
Widgets get an automatic title. You can optionally customize the title here.

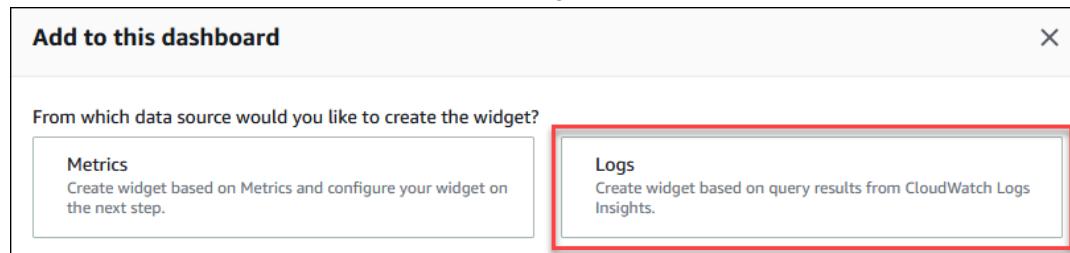

**Preview**  
This is how your chart will appear in your dashboard.  
**Autovacuum Duration - Avg and Max**

9. (Optional) Add more widgets based on your log query results.

- a. Choose **Add widget**.
- b. Choose a widget type, such as **Line**.

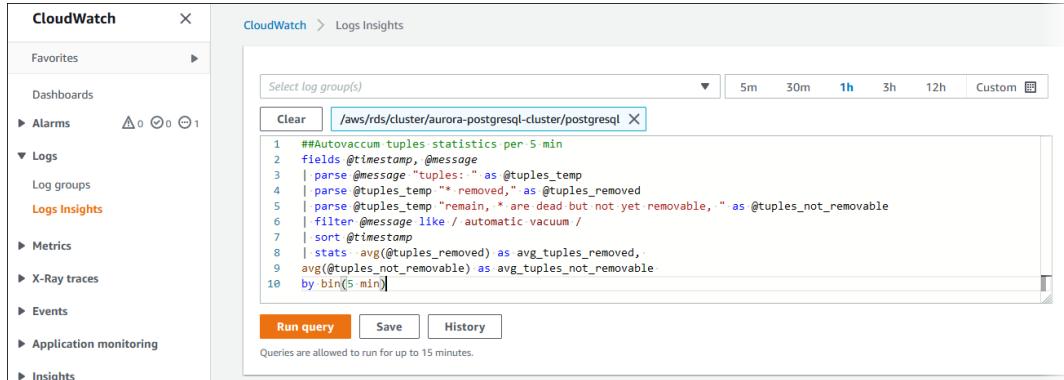

- c. In the **Add to this dashboard** window, choose **Logs**.

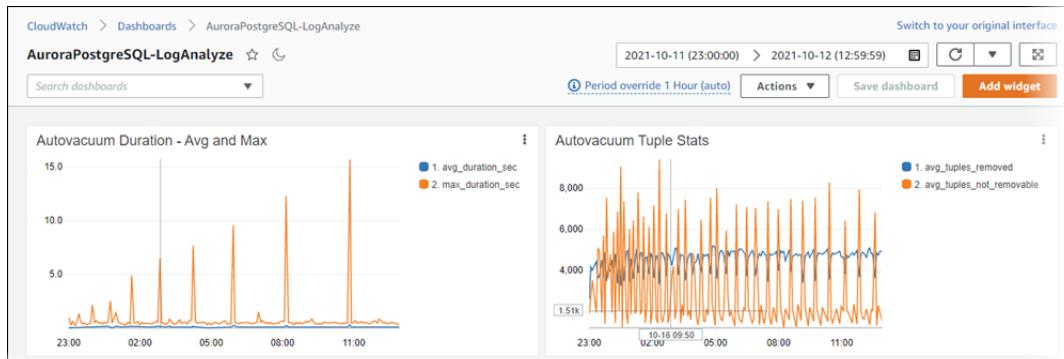

- d. In **Select log group(s)**, select the log group for your DB cluster.
- e. In the query editor, delete the query that is currently shown, enter the following, and then choose **Run query**.

```
##Autovacuum tuples statistics per 5 min
fields @timestamp, @message
| parse @message "tuples: " as @tuples_temp
| parse @tuples_temp "* removed," as @tuples_removed
| parse @tuples_temp "remain, * are dead but not yet removable, " as
@tuples_not_removable
| filter @message like / automatic vacuum /
| sort @timestamp
| stats avg(@tuples_removed) as avg_tuples_removed,
avg(@tuples_not_removable) as avg_tuples_not_removable
by bin(5 min)
```

f. Choose **Create widget**.

Your dashboard should look similar to the following image.

## Using machine learning (ML) with Aurora PostgreSQL

With Aurora machine learning, you can add machine learning–based predictions to database applications using the SQL language. Aurora machine learning uses a highly optimized integration between the Aurora database and the AWS machine learning (ML) services SageMaker and Amazon Comprehend.

Benefits of Aurora machine learning include the following:

- You can add ML–based predictions to your existing database applications. You don't need to build custom integrations or learn separate tools. You can embed machine learning processing directly into your SQL query as calls to functions.
- The ML integration is a fast way to enable ML services to work with transactional data. You don't have to move the data out of the database to perform the machine learning operations. You don't have to convert or reimport the results of the machine learning operations to use them in your database application.
- You can use your existing governance policies to control who has access to the underlying data and to the generated insights.

AWS machine learning services are managed services that you set up and run in their own production environments. Currently, Aurora machine learning integrates with Amazon Comprehend for sentiment analysis and SageMaker for a wide variety of ML algorithms.

For general information about Amazon Comprehend, see [Amazon Comprehend](#). For details about using Aurora and Amazon Comprehend together, see [Using Amazon Comprehend for natural language processing \(p. 1275\)](#).

For general information about SageMaker, see [SageMaker](#). For details about using Aurora and SageMaker together, see [Using SageMaker to run your own ML models \(p. 1277\)](#).

**Note**

Aurora machine learning for PostgreSQL connects an Aurora cluster to SageMaker or Amazon Comprehend services only within the same AWS Region.

**Topics**

- [Prerequisites for Aurora machine learning \(p. 1273\)](#)
- [Enabling Aurora machine learning \(p. 1273\)](#)
- [Using Amazon Comprehend for natural language processing \(p. 1275\)](#)
- [Exporting data to Amazon S3 for SageMaker model training \(p. 1276\)](#)
- [Using SageMaker to run your own ML models \(p. 1277\)](#)
- [Best practices with Aurora machine learning \(p. 1280\)](#)
- [Monitoring Aurora machine learning \(p. 1283\)](#)
- [PostgreSQL function reference for Aurora machine learning \(p. 1285\)](#)
- [Manually setting up IAM roles for SageMaker and Amazon Comprehend using the AWS CLI \(p. 1286\)](#)

## Prerequisites for Aurora machine learning

You can upgrade an Aurora cluster that's running a lower version of Aurora PostgreSQL to a supported higher version if you want to use Aurora machine learning with that cluster. For more information, see [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL \(p. 1415\)](#).

For more information about Regions and Aurora version availability, see [Aurora machine learning \(p. 24\)](#).

## Enabling Aurora machine learning

Enabling the ML capabilities involves the following steps.

**Topics**

- [Setting up IAM access to AWS machine learning services \(p. 1273\)](#)
- [Installing the aws\\_ml extension for model inference \(p. 1275\)](#)

## Setting up IAM access to AWS machine learning services

Before you can access SageMaker and Amazon Comprehend services, you set up AWS Identity and Access Management (IAM) roles. You then add the IAM roles to the Aurora PostgreSQL cluster. These roles authorize the users of your Aurora PostgreSQL database to access AWS ML services.

You can do IAM setup automatically by using the AWS Management Console as shown here. To use the AWS CLI to set up IAM access, see [Manually setting up IAM roles for SageMaker and Amazon Comprehend using the AWS CLI \(p. 1286\)](#).

### Automatically connecting an Aurora DB cluster to AWS services using the console

Aurora machine learning requires that your DB cluster use some combination of Amazon S3, SageMaker, and Amazon Comprehend. Amazon Comprehend is for sentiment analysis. SageMaker is for a wide variety of machine learning algorithms.

For Aurora machine learning, you use Amazon S3 only for training SageMaker models. You only need to use Amazon S3 with Aurora machine learning if you don't already have a trained model available and the training is your responsibility.

To connect a DB cluster to these services requires that you set up an AWS Identity and Access Management (IAM) role for each Amazon service. The IAM role enables users of your DB cluster to authenticate with the corresponding service.

To generate the IAM roles for SageMaker, Amazon Comprehend, or Amazon S3, repeat the following steps for each service that you need.

### To connect a DB cluster to an Amazon service

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the Aurora PostgreSQL DB cluster that you want to use.
3. Choose the **Connectivity & security** tab.
4. Choose **Select a service to connect to this cluster** in the **Manage IAM roles** section.
5. Choose the service that you want to connect to from the list:
  - **Amazon S3**
  - **Amazon Comprehend**
  - **SageMaker**
6. Choose **Connect service**.
7. Enter the required information for the specific service on the **Connect cluster** window:
  - For SageMaker, enter the Amazon Resource Name (ARN) of a SageMaker endpoint.

From the navigation pane of the [SageMaker console](#), choose **Endpoints** and copy the ARN of the endpoint you want to use. For details about what the endpoint represents, see [Deploy a Model in Amazon SageMaker](#).

- For Amazon Comprehend, you don't specify any additional parameters.
- For Amazon S3, enter the ARN of an Amazon S3 bucket to use.

The format of an Amazon S3 bucket ARN is `arn:aws:s3:::bucket_name`. Ensure that the Amazon S3 bucket you use is set up with the requirements for training SageMaker models. When you train a model, your Aurora DB cluster requires permission to export data to the Amazon S3 bucket, and also to import data from the bucket.

For more about an Amazon S3 bucket ARN, see [Specifying resources in a policy](#) in the *Amazon Simple Storage Service User Guide*. For more about using an Amazon S3 bucket with SageMaker, see [Step 1: Create an Amazon S3 bucket](#) in the *Amazon SageMaker Developer Guide*.

8. Choose **Connect service**.
9. Aurora creates a new IAM role and adds it to the DB cluster's list of **Current IAM roles for this cluster**. The IAM role's status is initially **In progress**. The IAM role name is autogenerated with the following pattern for each connected service:
  - The Amazon S3 IAM role name pattern is `rds-cluster_ID-S3-role-timestamp`.
  - The SageMaker IAM role name pattern is `rds-cluster_ID-SageMaker-role-timestamp`.
  - The Amazon Comprehend IAM role name pattern is `rds-cluster_ID-Comprehend-role-timestamp`.

Aurora also creates a new IAM policy and attaches it to the role. The policy name follows a similar naming convention and also has a timestamp.

## Installing the aws\_ml extension for model inference

After you create the required IAM roles and associate them with the Aurora PostgreSQL DB cluster, install the functions that use the SageMaker and Amazon Comprehend functionality. The aws\_ml Aurora PostgreSQL extension provides the aws\_sagemaker.invoke\_endpoint function that communicates directly with SageMaker. The aws\_ml extension also provides the aws\_comprehend.detect\_sentiment function that communicates directly with Amazon Comprehend.

To install these functions in a specific database, enter the following SQL command at a psql prompt.

```
psql>CREATE EXTENSION IF NOT EXISTS aws_ml CASCADE;
```

If you create the aws\_ml extension in the template1 default database, then the functions are available in each new database that you create.

To verify the installation, enter the following at a psql prompt.

```
psql>\dx
```

If you set up an IAM role for Amazon Comprehend, you can verify the setup as follows.

```
SELECT sentiment FROM aws_comprehend.detect_sentiment(null, 'I like it!', 'en');
```

When you install the aws\_ml extension, the aws\_ml administrative role is created and granted to the rds\_superuser role. Separate schemas are also created for the aws\_sagemaker service and for the aws\_comprehend service. The rds\_superuser role is made the OWNER of both of these schemas.

For users or roles to obtain access to the functions in the aws\_ml extension, grant EXECUTE privilege on those functions. You can subsequently REVOKE the privileges, if needed. EXECUTE privileges are revoked from PUBLIC on the functions of these schemas by default. In a multi-tenant database configuration, to prevent tenants from accessing the functions use REVOKE USAGE on one or more of the ML service schemas.

For a reference to the installed functions of the aws\_ml extension, see [PostgreSQL function reference for Aurora machine learning \(p. 1285\)](#).

## Using Amazon Comprehend for natural language processing

Amazon Comprehend uses machine learning to find insights and relationships in text. Amazon Comprehend uses natural language processing to extract insights about the content of documents. It develops insights by recognizing the entities, key phrases, language, sentiments, and other common elements in a document. You can use this Aurora machine learning service with very little machine learning experience.

Aurora machine learning uses Amazon Comprehend for sentiment analysis of text that is stored in your database. A *sentiment* is an opinion expressed in text. Sentiment analysis identifies and categorizes sentiments to determine if the attitude towards something (such as a topic or product) is positive, negative, or neutral.

### Note

Amazon Comprehend is currently available only in some AWS Regions. To check in which AWS Regions you can use Amazon Comprehend, see [the AWS Region table](#) page on the AWS site.

For example, using Amazon Comprehend you can analyze contact center call-in documents to detect caller sentiment and better understand caller-agent dynamics. You can find a further description in the post [Analyzing contact center calls](#) on the AWS Machine Learning blog.

You can also combine sentiment analysis with the analysis of other information in your database using a single query. For example, you can detect the average sentiment of call-in center documents for issues that combine the following:

- Open for more than 30 days.
- About a specific product or feature.
- Made by the customers who have the greatest social media influence.

Using Amazon Comprehend from Aurora machine learning is as easy as calling a SQL function. When you installed the `aws_ml` extension ([Installing the aws\\_ml extension for model inference \(p. 1275\)](#)), it provides the [aws\\_comprehend.detect\\_sentiment \(p. 1285\)](#) function to perform sentiment analysis through Amazon Comprehend.

For each text fragment that you analyze, this function helps you determine the sentiment and the confidence level. A typical Amazon Comprehend query looks for table rows where the sentiment has a certain value (POSITIVE or NEGATIVE), with a confidence level greater than a certain percent.

For example, the following query shows how to determine the average sentiment of documents in a database table, `myTable.document`. The query considers only documents where the confidence of the assessment is at least 80 percent. In the following example, English (`en`) is the language of the sentiment text.

```
SELECT AVG(CASE s.sentiment
    WHEN 'POSITIVE' then 1
    WHEN 'NEGATIVE' then -1
    ELSE 0 END) as avg_sentiment, COUNT(*) AS total
FROM myTable, aws_comprehend.detect_sentiment (myTable.document, 'en') s
WHERE s.confidence >= 0.80;
```

To avoid your being charged for sentiment analysis more than once per table row, you can materialize the results of the analysis once per row. Do this on the rows of interest. In the following example, French (`fr`) is the language of the sentiment text.

```
-- *Example:* Update the sentiment and confidence of French text.
--
UPDATE clinician_notes
SET sentiment = (aws_comprehend.detect_sentiment (french_notes, 'fr')).sentiment,
    confidence = (aws_comprehend.detect_sentiment (french_notes, 'fr')).confidence
WHERE
    clinician_notes.french_notes IS NOT NULL AND
    LENGTH(TRIM(clinician_notes.french_notes)) > 0 AND
    clinician_notes.sentiment IS NULL;
```

For more information on optimizing your function calls, see [Best practices with Aurora machine learning \(p. 1280\)](#).

For information about parameters and return types for the sentiment detection function, see [aws\\_comprehend.detect\\_sentiment \(p. 1285\)](#).

## Exporting data to Amazon S3 for SageMaker model training

Depending on how your team divides the machine learning tasks, you might not perform model training. If someone else provides the SageMaker model for you, you can skip this section.

To train SageMaker models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by SageMaker to train your model before it is deployed. You can query data from an Aurora PostgreSQL DB

cluster and save it directly into text files stored in an Amazon S3 bucket. Then SageMaker consumes the data from the Amazon S3 bucket for training. For more about SageMaker model training, see [Train a model with Amazon SageMaker](#).

**Note**

When you create an S3 bucket for SageMaker model training or batch scoring, always include the text `sagemaker` in the S3 bucket name. For more information about creating an S3 bucket for SageMaker, see [Step 1: Create an Amazon S3 bucket](#).

For more information about exporting your data, see [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3 \(p. 1243\)](#).

## Using SageMaker to run your own ML models

SageMaker is a fully managed machine learning service. With SageMaker, data scientists and developers build and train machine learning models. Then they can directly deploy the models into a production-ready hosted environment.

SageMaker provides access to your data sources so that you can perform exploration and analysis without managing the hardware infrastructure for servers. SageMaker also provides common machine learning algorithms that are optimized to run efficiently against extremely large datasets in a distributed environment. With native support for bring-your-own-algorithms and frameworks, SageMaker offers flexible distributed training options that adjust to your specific workflows.

**Note**

Currently, Aurora machine learning supports any SageMaker endpoint that can read and write the comma-separated value (CSV) format, through a `ContentType` value of `text/csv`. The built-in SageMaker algorithms that currently accept this format are Random Cut Forest, Linear Learner, and XGBoost.

Be sure to deploy the model you are using in the same AWS Region as your Aurora PostgreSQL cluster. Aurora machine learning always invokes SageMaker endpoints in the same AWS Region as your Aurora cluster.

When you install the `aws_ml` extension (as described in [Installing the aws\\_ml extension for model inference \(p. 1275\)](#)), it provides the `aws_sagemaker.invoke_endpoint` (p. 1285) function. You use this function to invoke your SageMaker model and perform model inference directly from within your SQL database application.

### Topics

- [Creating a user-defined function to invoke a SageMaker model \(p. 1277\)](#)
- [Passing an array as input to a SageMaker model \(p. 1278\)](#)
- [Specifying batch size when invoking a SageMaker model \(p. 1279\)](#)
- [Invoking a SageMaker model that has multiple outputs \(p. 1279\)](#)

## Creating a user-defined function to invoke a SageMaker model

Create a separate user-defined function to call `aws_sagemaker.invoke_endpoint` for each of your SageMaker models. Your user-defined function represents the SageMaker endpoint hosting the model. The `aws_sagemaker.invoke_endpoint` function runs within the user-defined function. User-defined functions provide many advantages:

- You can give your ML model its own name instead of only calling `aws_sagemaker.invoke_endpoint` for all of your ML models.
- You can specify the model endpoint URL in just one place in your SQL application code.
- You can control `EXECUTE` privileges to each ML function independently.

- You can declare the model input and output types using SQL types. SQL enforces the number and type of arguments passed to your ML model and performs type conversion if necessary. Using SQL types will also translate `SQL NULL` to the appropriate default value expected by your ML model.
- You can reduce the maximum batch size if you want to return the first few rows a little faster.

To specify a user-defined function, use the SQL data definition language (DDL) statement `CREATE FUNCTION`. When you define the function, you specify the following:

- The input parameters to the model.
- The specific SageMaker endpoint to invoke.
- The return type.

The user-defined function returns the inference computed by the SageMaker endpoint after running the model on the input parameters. The following example creates a user-defined function for an SageMaker model with two input parameters.

```
CREATE FUNCTION classify_event (IN arg1 INT, IN arg2 DATE, OUT category INT)
AS $$$
    SELECT aws_sagemaker.invoke_endpoint (
        'sagemaker_model_endpoint_name', NULL,
        arg1, arg2
        -- model inputs are separate arguments
        )::INT
        -- cast the output to INT
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:

- The `aws_sagemaker.invoke_endpoint` function input can be one or more parameters of any data type.  
For more details about parameters, see the [aws\\_sagemaker.invoke\\_endpoint \(p. 1285\)](#) function reference.
- This example uses an INT output type. If you cast the output from a varchar type to a different type, then it must be cast to a PostgreSQL builtin scalar type such as INTEGER, REAL, FLOAT, or NUMERIC. For more information about these types, see [Data types](#) in the PostgreSQL documentation.
- Specify `PARALLEL SAFE` to enable parallel query processing. For more information, see [Exploiting parallel query processing \(p. 1282\)](#).
- Specify `COST 5000` to estimate the cost of running the function. Use a positive number giving the estimated run cost for the function, in units of `cpu_operator_cost`.

## Passing an array as input to a SageMaker model

The [aws\\_sagemaker.invoke\\_endpoint \(p. 1285\)](#) function can have up to 100 input parameters, which is the limit for PostgreSQL functions. If the SageMaker model requires more than 100 parameters of the same type, pass the model parameters as an array.

The following example creates a user-defined function that passes an array as input to the SageMaker regression model.

```
CREATE FUNCTION regression_model (params REAL[], OUT estimate REAL)
AS $$$
    SELECT aws_sagemaker.invoke_endpoint (
        'sagemaker_model_endpoint_name', NULL,
        params
        -- model input parameters as an array
        )::REAL
        -- cast output to REAL
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

## Specifying batch size when invoking a SageMaker model

The following example creates a user-defined function for a SageMaker model that sets the batch size default to NULL. The function also allows you to provide a different batch size when you invoke it.

```
CREATE FUNCTION classify_event (
    IN event_type INT, IN event_day DATE, IN amount REAL, -- model inputs
    max_rows_per_batch INT DEFAULT NULL, -- optional batch size limit
    OUT category INT) -- model output
AS $$$
    SELECT aws_sagemaker.invoke_endpoint (
        'sagemaker_model_endpoint_name', max_rows_per_batch,
        event_type, event_day, COALESCE(amount, 0.0)
        )::INT -- casts output to type INT
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:

- Use the optional `max_rows_per_batch` parameter to provide control of the number of rows for a batch-mode function invocation. If you use a value of NULL, then the query optimizer automatically chooses the maximum batch size. For more information, see [Optimizing batch-mode execution for Aurora machine learning function calls \(p. 1280\)](#).
- By default, passing NULL as a parameter's value is translated to an empty string before passing to SageMaker. For this example the inputs have different types.
- If you have a non-text input, or text input that needs to default to some value other than an empty string, use the `COALESCE` statement. Use `COALESCE` to translate NULL to the desired null replacement value in the call to `aws_sagemaker.invoke_endpoint`. For the `amount` parameter in this example, a NULL value is converted to 0.0.

## Invoking a SageMaker model that has multiple outputs

The following example creates a user-defined function for a SageMaker model that returns multiple outputs. Your function needs to cast the output of the `aws_sagemaker.invoke_endpoint` function to a corresponding data type. For example, you could use the built-in PostgreSQL point type for (x,y) pairs or a user-defined composite type.

This user-defined function returns values from a model that returns multiple outputs by using a composite type for the outputs.

```
CREATE TYPE company_forecasts AS (
    six_month_estimated_return real,
    one_year_bankruptcy_probability float);
CREATE FUNCTION analyze_company (
    IN free_cash_flow NUMERIC(18, 6),
    IN debt NUMERIC(18,6),
    IN max_rows_per_batch INT DEFAULT NULL,
    OUT prediction company_forecasts)
AS $$$
    SELECT (aws_sagemaker.invoke_endpoint(
        'endpt_name', max_rows_per_batch,
        free_cash_flow, debt))::company_forecasts;
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

For the composite type, use fields in the same order as they appear in the model output and cast the output of `aws_sagemaker.invoke_endpoint` to your composite type. The caller can extract the individual fields either by name or with PostgreSQL `".*"` notation.

## Best practices with Aurora machine learning

Most of the work in an `aws_ml` function call happens within the external Aurora machine learning service. This separation allows you to scale the resources for the machine learning service independent of your Aurora cluster. Within Aurora, you mostly focus on making the user-defined function calls themselves as efficient as possible. Some aspects that you can influence from your Aurora cluster include:

- The `max_rows_per_batch` setting for calls to the `aws_ml` functions.
- The number of virtual CPUs of the database instance, which determines the maximum degree of parallelism that the database might use when running your ML functions.
- the PostgreSQL parameters that control parallel query processing.

### Topics

- [Optimizing batch-mode execution for Aurora machine learning function calls \(p. 1280\)](#)
- [Exploiting parallel query processing \(p. 1282\)](#)
- [Using materialized views and materialized columns \(p. 1283\)](#)

## Optimizing batch-mode execution for Aurora machine learning function calls

Typically PostgreSQL runs functions one row at a time. Aurora machine learning can minimize this overhead by combining the calls to the external Aurora machine learning service for many rows into batches with an approach called *batch-mode execution*. In batch mode, Aurora machine learning receives the responses for a batch of input rows, and then delivers the responses back to the running query one row at a time. This optimization improves the throughput of your Aurora queries without limiting the PostgreSQL query optimizer.

Aurora automatically uses batch mode if the function is referenced from the `SELECT` list, a `WHERE` clause, or a `HAVING` clause. Note that top-level simple `CASE` expressions are eligible for batch-mode execution. Top-level searched `CASE` expressions are also eligible for batch-mode execution provided that the first `WHEN` clause is a simple predicate with a batch-mode function call.

Your user-defined function must be a `LANGUAGE SQL` function and should specify `PARALLEL SAFE` and `COST 5000`.

### Topics

- [Function migration from the SELECT statement to the FROM clause \(p. 1280\)](#)
- [Using the `max\_rows\_per\_batch` parameter \(p. 1281\)](#)
- [Verifying batch-mode execution \(p. 1281\)](#)

### Function migration from the SELECT statement to the FROM clause

Usually, an `aws_ml` function that is eligible for batch-mode execution is automatically migrated by Aurora to the `FROM` clause.

The migration of eligible batch-mode functions to the `FROM` clause can be examined manually on a per-query level. To do this, you use `EXPLAIN` statements (and `ANALYZE` and `VERBOSE`) and find the "Batch Processing" information below each batch-mode `Function Scan`. You can also use `EXPLAIN` (with `VERBOSE`) without running the query. You then observe whether the calls to the function appear as a `Function Scan` under a nested loop join that was not specified in the original statement.

In the following example, the presence of the nested loop join operator in the plan shows that Aurora migrated the `anomaly_score` function. It migrated this function from the `SELECT` list to the `FROM` clause, where it's eligible for batch-mode execution.

```
EXPLAIN (VERBOSE, COSTS false)
SELECT anomaly_score(ts.R.description) from ts.R;
          QUERY PLAN
-----
Nested Loop
  Output: anomaly_score((r.description)::text)
    -> Seq Scan on ts.r
      Output: r.id, r.description, r.score
    -> Function Scan on public.anomaly_score
      Output: anomaly_score.anomaly_score
      Function Call: anomaly_score((r.description)::text)
```

To disable batch-mode execution, set the `apg_enable_function_migration` parameter to `false`. This prevents the migration of `aws_ml` functions from the `SELECT` to the `FROM` clause. The following shows how.

```
SET apg_enable_function_migration = false;
```

The `apg_enable_function_migration` parameter is a Grand Unified Configuration (GUC) parameter that is recognized by the Aurora PostgreSQL `apg_plan_mgmt` extension for query plan management. To disable function migration in a session, use query plan management to save the resulting plan as an approved plan. At runtime, query plan management enforces the approved plan with its `apg_enable_function_migration` setting. This enforcement occurs regardless of the `apg_enable_function_migration` GUC parameter setting. For more information, see [Managing query execution plans for Aurora PostgreSQL \(p. 1290\)](#).

### Using the `max_rows_per_batch` parameter

The `max_rows_per_batch` parameter of the [aws\\_sagemaker.invoke\\_endpoint \(p. 1285\)](#) and [aws\\_comprehend.detect\\_sentiment \(p. 1285\)](#) functions influences how many rows are transferred to the Aurora machine learning service. The larger the dataset processed by the user-defined function, the larger you can make the batch size.

Batch-mode functions improve efficiency by building batches of rows that spread the cost of the Aurora machine learning function calls over a large number of rows. However, if a `SELECT` statement finishes early due to a `LIMIT` clause, then the batch can be constructed over more rows than the query uses. This approach can result in additional charges to your AWS account. To gain the benefits of batch-mode execution but avoid building batches that are too large, use a smaller value for the `max_rows_per_batch` parameter in your function calls.

If you do an `EXPLAIN (VERBOSE, ANALYZE)` of a query that uses batch-mode execution, you see a `FunctionScan` operator that is below a nested loop join. The number of loops reported by `EXPLAIN` tells you the number of times a row was fetched from the `FunctionScan` operator. If a statement uses a `LIMIT` clause, the number of fetches is consistent. To optimize the size of the batch, set the `max_rows_per_batch` parameter to this value. However, if the batch-mode function is referenced in a predicate in the `WHERE` clause or `HAVING` clause, then you probably can't know the number of fetches in advance. In this case, use the loops as a guideline and experiment with `max_rows_per_batch` to find a setting that optimizes performance.

### Verifying batch-mode execution

To see if a function ran in batch mode, use `EXPLAIN ANALYZE`. If batch-mode execution was used, then the query plan will include the information in a "Batch Processing" section.

```
EXPLAIN ANALYZE SELECT user-defined-function();
Batch Processing: num batches=1 avg/min/max batch size=3333.000/3333.000/3333.000
                                         avg/min/max batch call time=146.273/146.273/146.273
```

In this example, there was 1 batch that contained 3,333 rows, which took 146.273 ms to process. The "Batch Processing" section shows the following:

- How many batches there were for this function scan operation
- The batch size average, minimum, and maximum
- The batch execution time average, minimum, and maximum

Typically the final batch is smaller than the rest, which often results in a minimum batch size that is much smaller than the average.

To return the first few rows more quickly, set the `max_rows_per_batch` parameter to a smaller value.

To reduce the number of batch mode calls to the ML service when you use a `LIMIT` in your user-defined function, set the `max_rows_per_batch` parameter to a smaller value.

## Exploiting parallel query processing

To dramatically increase performance when processing a large number of rows, you can combine parallel query processing with batch mode processing. You can use parallel query processing for `SELECT`, `CREATE TABLE AS SELECT`, and `CREATE MATERIALIZED VIEW` statements.

### Note

PostgreSQL doesn't yet support parallel query for data manipulation language (DML) statements.

Parallel query processing occurs both within the database and within the ML service. The number of cores in the instance class of the database limits the degree of parallelism that can be used when running a query. The database server can construct a parallel query execution plan that partitions the task among a set of parallel workers. Then each of these workers can build batched requests containing tens of thousands of rows (or as many as are allowed by each service).

The batched requests from all of the parallel workers are sent to the endpoint for the AWS service (SageMaker, for example). Thus, the number and type of instances behind the AWS service endpoint also limits the degree of parallelism that can be usefully exploited. Even a two-core instance class can benefit significantly from parallel query processing. However, to fully exploit parallelism at higher K degrees, you need a database instance class that has at least K cores. You also need to configure the AWS service so that it can process K batched requests in parallel. For SageMaker, you need to configure the SageMaker endpoint for your ML model to have K initial instances of a sufficiently high-performing instance class.

To exploit parallel query processing, you can set the `parallel_workers` storage parameter of the table that contains the data that you plan to pass. You set `parallel_workers` to a batch-mode function such as `aws_comprehend.detect_sentiment`. If the optimizer chooses a parallel query plan, the AWS ML services can be called both in batch and in parallel. You can use the following parameters with the `aws_comprehend.detect_sentiment` function to get a plan with four-way parallelism.

```
-- If you change either of the following two parameters, you must restart
-- the database instance for the changes to take effect.
--
-- SET max_worker_processes to 8;  -- default value is 8
-- SET max_parallel_workers to 8;  -- not greater than max_worker_processes

--
SET max_parallel_workers_per_gather to 4;  -- not greater than max_parallel_workers

-- You can set the parallel_workers storage parameter on the table that the data
-- for the ML function is coming from in order to manually override the degree of
-- parallelism that would otherwise be chosen by the query optimizer
--
ALTER TABLE yourTable SET (parallel_workers = 4);
```

```
-- Example query to exploit both batch-mode execution and parallel query
--
EXPLAIN (verbose, analyze, buffers, hashes)
SELECT aws_comprehend.detect_sentiment(description, 'en')).*
FROM yourTable
WHERE id < 100;
```

For more about controlling parallel query, see [Parallel plans](#) in the PostgreSQL documentation.

## Using materialized views and materialized columns

When you invoke an AWS service such as SageMaker or Amazon Comprehend from your database, your account is charged according to the pricing policy of that service. To minimize charges to your account, you can materialize the result of calling the AWS service into a materialized column so that the AWS service is not called more than once per input row. If desired, you can add a `materializedAt` timestamp column to record the time at which the columns were materialized.

The latency of an ordinary single-row `INSERT` statement is typically much less than the latency of calling a batch-mode function. Thus, you might not be able to meet the latency requirements of your application if you invoke the batch-mode function for every single-row `INSERT` that your application performs. To materialize the result of calling an AWS service into a materialized column, high-performance applications generally need to populate the materialized columns. To do this, they periodically issue an `UPDATE` statement that operates on a large batch of rows at the same time.

`UPDATE` takes a row-level lock that can impact a running application. So you might need to use `SELECT ... FOR UPDATE SKIP LOCKED`, or use `MATERIALIZED VIEW`.

Analytics queries that operate on a large number of rows in real time can combine batch-mode materialization with real-time processing. To do this, these queries assemble a `UNION ALL` of the pre-materialized results with a query over the rows that don't yet have materialized results. In some cases, such a `UNION ALL` is needed in multiple places, or the query is generated by a third-party application. If so, you can create a `VIEW` to encapsulate the `UNION ALL` operation so this detail isn't exposed to the rest of the SQL application.

You can use a materialized view to materialize the results of an arbitrary `SELECT` statement at a snapshot in time. You can also use it to refresh the materialized view at any time in the future. Currently PostgreSQL doesn't support incremental refresh, so each time the materialized view is refreshed the materialized view is fully recomputed.

You can refresh materialized views with the `CONCURRENTLY` option, which updates the contents of the materialized view without taking an exclusive lock. Doing this allows a SQL application to read from the materialized view while it's being refreshed.

## Monitoring Aurora machine learning

To monitor the functions in the `aws_ml` package, set the `track_functions` parameter and then query the [PostgreSQL pg\\_stat\\_user\\_functions view](#).

For information about monitoring the performance of the SageMaker operations called from Aurora machine learning functions, see [Monitor Amazon SageMaker](#).

To set `track_functions` at the session level, run the following.

```
SET track_functions = 'all';
```

Use one of the following values:

- **all** – Track C language functions and SQL language functions that aren't placed inline. To track the `aws_ml` functions, use `all` because these functions are implemented in C.
- **p1** – Track only procedural-language functions.
- **none** – Disable function statistics tracking.

After enabling `track_functions` and running your user-defined ML function, query the `pg_stat_user_functions` view to get information. The view includes the number of calls, `total_time` and `self_time` for each function. To view the statistics for the `aws_sagemaker.invoke_endpoint` and `aws_comprehend.detect_sentiment` functions, filter the results by schema names starting with `aws_`.

```
run your statement
SELECT * FROM pg_stat_user_functions WHERE schemaname LIKE 'aws_%';
SELECT pg_stat_reset(); -- To clear statistics
```

To find the names of your SQL functions that call the `aws_sagemaker.invoke_endpoint` function, query the source code of the functions in the [PostgreSQL pg\\_proc catalog](#) table.

```
SELECT proname FROM pg_proc WHERE prosrc LIKE '%invoke_endpoint%';
```

## Using query plan management to monitor ML functions

If you captured plans using the `apg_plan_mgmt` extension of query plan management, you can then search through all the statements in your workload that refer to these function names. In your search, you can check `plan_outline` to see if batch-mode execution was used. You can also list statement statistics such as execution time and plan cost. Plans that use batch-mode function scans contain a `FuncScan` operator in the plan outline. Functions that aren't run as a join don't contain a `FuncScan` operator.

For more about query plan management, see [Managing query execution plans for Aurora PostgreSQL \(p. 1290\)](#).

To find calls to the `aws_sagemaker.invoke_endpoint` function that don't use batch mode, use the following statement.

```
\dx apg_plan_mgmt

SELECT sql_hash, plan_hash, status, environment_variables,
       sql_text::varchar(50), plan_outline
FROM pg_proc, apg_plan_mgmt.dba_plans
WHERE
    prosrc LIKE '%invoke_endpoint%' AND
    sql_text LIKE '%' || proname || '%' AND
    plan_outline NOT LIKE '%FuncScan%';
```

The example preceding searches all statements in your workload that call SQL functions that in turn call the `aws_sagemaker.invoke_endpoint` function.

To obtain detailed runtime statistics for each of these statements, call the `apg_plan_mgmt.get_explain_stmt` function.

```
SELECT apg_plan_mgmt.get_explain_stmt(sql_hash, plan_hash, 'analyze,verbose,buffers')
FROM pg_proc, apg_plan_mgmt.dba_plans
WHERE
    prosrc LIKE '%invoke_endpoint%' AND
    sql_text LIKE '%' || proname || '%' AND
    plan_outline NOT LIKE '%FuncScan%';
```

## PostgreSQL function reference for Aurora machine learning

### Functions

- [aws\\_comprehend.detect\\_sentiment \(p. 1285\)](#)
- [aws\\_sagemaker.invoke\\_endpoint \(p. 1285\)](#)

### [aws\\_comprehend.detect\\_sentiment](#)

Performs sentiment analysis using Amazon Comprehend. For more about usage, see [Using Amazon Comprehend for natural language processing \(p. 1275\)](#).

#### Syntax

```
aws_comprehend.detect_sentiment (
    IN input_text varchar,
    IN language_code varchar,
    IN max_rows_per_batch int,
    OUT sentiment varchar,
    OUT confidence real)
)
```

#### Input Parameters

##### **input\_text**

The text to detect sentiment on.

##### **language\_code**

The language of the `input_text`. For valid values, see [Languages supported in Amazon Comprehend](#).

##### **max\_rows\_per\_batch**

The maximum number of rows per batch for batch-mode processing. For more information, see [Optimizing batch-mode execution for Aurora machine learning function calls \(p. 1280\)](#).

#### Output Parameters

##### **sentiment**

The sentiment of the text. Valid values are POSITIVE, NEGATIVE, NEUTRAL, or MIXED.

##### **confidence**

The degree of confidence in the `sentiment` value. Values range between 1.0 for 100% to 0.0 for 0%.

### [aws\\_sagemaker.invoke\\_endpoint](#)

After you train a model and deploy it into production using SageMaker services, your client applications use the `aws_sagemaker.invoke_endpoint` function to get inferences from the model. The model must be hosted at the specified endpoint and must be in the same AWS Region as the database instance. For more about usage, see [Using SageMaker to run your own ML models \(p. 1277\)](#).

#### Syntax

```
aws_sagemaker.invoke_endpoint(
```

```
    IN endpoint_name varchar,
    IN max_rows_per_batch int,
    VARIADIC model_input "any",
    OUT model_output varchar
)
```

## Input Parameters

### **endpoint\_name**

An endpoint URL that is AWS Region-independent.

### **max\_rows\_per\_batch**

The maximum number of rows per batch for batch-mode processing. For more information, see [Optimizing batch-mode execution for Aurora machine learning function calls \(p. 1280\)](#).

### **model\_input**

One or more input parameters for the ML model. These can be any data type.

PostgreSQL allows you to specify up to 100 input parameters for a function. Array data types must be one-dimensional, but can contain as many elements as are expected by the SageMaker model. The number of inputs to a SageMaker model is bounded only by the SageMaker 6 MB message size limit.

## Output Parameters

### **model\_output**

The SageMaker model's output parameter, as text.

## Usage Notes

The `aws_sagemaker.invoke_endpoint` function connects only to a model endpoint in the same AWS Region. If your database instance has replicas in multiple AWS Regions, always deploy each Amazon SageMaker model to all of those AWS Regions.

Calls to `aws_sagemaker.invoke_endpoint` are authenticated using the SageMaker IAM role for the database instance.

SageMaker model endpoints are scoped to an individual account and are not public. The `endpoint_name` URL doesn't contain the account ID. SageMaker determines the account ID from the authentication token that is supplied by the SageMaker IAM role of the database instance.

## Manually setting up IAM roles for SageMaker and Amazon Comprehend using the AWS CLI

### Note

If you use the AWS Management Console, AWS does the IAM setup for you automatically. In this case, you can skip the following information and follow the procedure in [Automatically connecting an Aurora DB cluster to AWS services using the console \(p. 1273\)](#).

Setting up the IAM roles for SageMaker or Amazon Comprehend using the AWS CLI or the RDS API consists of the following steps:

1. Create an IAM policy to specify which SageMaker endpoints can be invoked by your Aurora PostgreSQL cluster or to enable access to Amazon Comprehend.
2. Create an IAM role to permit your Aurora PostgreSQL database cluster to access AWS ML services. Also attach the IAM policy created preceding to the IAM role created here.

3. Associate the IAM role that you created preceding to the Aurora PostgreSQL database cluster to permit access to AWS ML services.

#### Topics

- [Creating an IAM policy to access SageMaker using the AWS CLI \(p. 1287\)](#)
- [Creating an IAM policy to access Amazon Comprehend using the AWS CLI \(p. 1287\)](#)
- [Creating an IAM role to access SageMaker and Amazon Comprehend \(p. 1288\)](#)
- [Associating an IAM role with an Aurora PostgreSQL DB cluster using the AWS CLI \(p. 1288\)](#)

## Creating an IAM policy to access SageMaker using the AWS CLI

#### Note

Aurora can create the IAM policy for you automatically. You can skip the following information and use the procedure in [Automatically connecting an Aurora DB cluster to AWS services using the console \(p. 1273\)](#).

The following policy adds the permissions required by Aurora PostgreSQL to invoke a SageMaker function on your behalf. You can specify all of your SageMaker endpoints that you need your database applications to access from your Aurora PostgreSQL cluster in a single policy.

#### Note

This policy enables you to specify the AWS Region for a SageMaker endpoint. However, an Aurora PostgreSQL cluster can only invoke SageMaker models deployed in the same AWS Region as the cluster.

```
{ "Version": "2012-10-17", "Statement": [ { "Sid": "AllowAuroraToInvokeRCFEndPoint", "Effect": "Allow", "Action": "sagemaker:InvokeEndpoint", "Resource": "arn:aws:sagemaker:region:123456789012:endpoint/endpointName" } ] }
```

The following AWS CLI command creates an IAM policy with these options.

```
aws iam create-policy --policy-name policy_name --policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowAuroraToInvokeRCFEndPoint",  
            "Effect": "Allow",  
            "Action": "sagemaker:InvokeEndpoint",  
            "Resource": "arn:aws:sagemaker:region:123456789012:endpoint/endpointName"  
        }  
    ]  
}'
```

For the next step, see [Creating an IAM role to access SageMaker and Amazon Comprehend \(p. 1288\)](#).

## Creating an IAM policy to access Amazon Comprehend using the AWS CLI

#### Note

Aurora can create the IAM policy for you automatically. You can skip the following information and use the procedure in [Automatically connecting an Aurora DB cluster to AWS services using the console \(p. 1273\)](#).

The following policy adds the permissions required by Aurora PostgreSQL to invoke Amazon Comprehend on your behalf.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
}
```

```
{  
    "Sid": "AllowAuroraToInvokeComprehendDetectSentiment",  
    "Effect": "Allow",  
    "Action": [  
        "comprehend:DetectSentiment",  
        "comprehend:BatchDetectSentiment"  
    ],  
    "Resource": "*"  
}  
]  
}
```

### To create an IAM policy to grant access to Amazon Comprehend

1. Open the [IAM management console](#).
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **Comprehend**.
5. For **Actions**, choose **Detect Sentiment** and **BatchDetectSentiment**.
6. Choose **Review policy**.
7. For **Name**, enter a name for your IAM policy. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.
8. Choose **Create policy**.

For the next step, see [Creating an IAM role to access SageMaker and Amazon Comprehend \(p. 1288\)](#).

### Creating an IAM role to access SageMaker and Amazon Comprehend

#### Note

Aurora can create the IAM role for you automatically. You can skip the following information and use the procedure in [Automatically connecting an Aurora DB cluster to AWS services using the console \(p. 1273\)](#).

After you create the IAM policies, create an IAM role that the Aurora PostgreSQL DB cluster can assume for your database users to access ML services. To create an IAM role, follow the steps described in [Creating a role to delegate permissions to an IAM user](#).

Attach the preceding policies to the IAM role you create. For more information, see [Attaching an IAM policy to an IAM user or role \(p. 1689\)](#).

For more information about IAM roles, see [IAM roles in the IAM User Guide](#).

For the next step, see [Associating an IAM role with an Aurora PostgreSQL DB cluster using the AWS CLI \(p. 1288\)](#).

### Associating an IAM role with an Aurora PostgreSQL DB cluster using the AWS CLI

#### Note

Aurora can associate an IAM role with your DB cluster for you automatically. You can skip the following information and use the procedure in [Automatically connecting an Aurora DB cluster to AWS services using the console \(p. 1273\)](#).

The last process in setting up IAM access is to associate the IAM role and its IAM policy with your Aurora PostgreSQL DB cluster. Do the following:

1. Add the role to the list of associated roles for a DB cluster.

To associate the role with your DB cluster, use the AWS Management Console or the [add-role-to-db-cluster](#) AWS CLI command.

- **To add an IAM role for a PostgreSQL DB cluster using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the PostgreSQL DB cluster name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this cluster**.
4. Under **Feature**, choose **SageMaker** or **Comprehend**.
5. Choose **Add role**.

- **To add an IAM role for a PostgreSQL DB cluster using the CLI**

Use the following command to add the role to the PostgreSQL DB cluster named `my-db-cluster`. Replace `your-role-arn` with the role ARN that you noted in a previous step. For the value of the `--feature-name` option, use `SageMaker`, `Comprehend`, or `s3Export` depending on which service you want to use.

### Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-cluster \
--db-cluster-identifier my-db-cluster \
--feature-name external-service \
--role-arn your-role-arn \
--region your-region
```

For Windows:

```
aws rds add-role-to-db-cluster ^
--db-cluster-identifier my-db-cluster ^
--feature-name external-service ^
--role-arn your-role-arn ^
--region your-region
```

2. Set the cluster-level parameter for each AWS ML service to the ARN for the associated IAM role.

Use the `electroencephalographic`, `miscomprehended`, or both parameters depending on which AWS ML services you intend to use with your Aurora cluster.

Cluster-level parameters are grouped into DB cluster parameter groups. To set the preceding cluster parameters, use an existing custom DB cluster group or create a new one. To create a new DB cluster parameter group, call the `create-db-cluster-parameter-group` command from the AWS CLI, for example:

```
aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-
name AllowAWSAccessToExternalServices \
--db-parameter-group-family aurora-postgresql-group --description "Allow access to
Amazon S3, Amazon SageMaker, and Amazon Comprehend"
```

Set the appropriate cluster-level parameter or parameters and the related IAM role ARN values in your DB cluster parameter group. Do the following.

```
aws rds modify-db-cluster-parameter-group \
--db-cluster-parameter-group-name AllowAWSAccessToExternalServices \
--parameters
"ParameterName=aws_default_s3_role,ParameterValue=arn:aws:iam::123456789012:role/
AllowAuroraS3Role,ApplyMethod=pending-reboot" \
```

```
--parameters
"ParameterName=aws_default_sagemaker_role,ParameterValue=arn:aws:iam::123456789012:role/
AllowAuroraSageMakerRole,ApplyMethod=pending-reboot" \
--parameters
"ParameterName=aws_default_comprehend_role,ParameterValue=arn:aws:iam::123456789012:role/
AllowAuroraComprehendRole,ApplyMethod=pending-reboot"
```

Modify the DB cluster to use the new DB cluster parameter group. Then, reboot the cluster. The following shows how.

```
aws rds modify-db-cluster --db-cluster-identifier your_cluster_id --db-cluster-parameter-
group-nameAllowAWSAccessToExternalServices
aws rds failover-db-cluster --db-cluster-identifier your_cluster_id
```

When the instance has rebooted, your IAM roles are associated with your DB cluster.

## Managing query execution plans for Aurora PostgreSQL

With query plan management for Amazon Aurora PostgreSQL-Compatible Edition, you can control how and when query execution plans change. Query plan management has two main objectives:

- Preventing plan regressions when the database system changes
- Controlling when the query optimizer can use new plans

The quality and consistency of query optimization have a major impact on the performance and stability of any relational database management system (RDBMS). Query optimizers create a query execution plan for a SQL statement at a specific point in time. As conditions change, the optimizer might pick a different plan that makes performance better or worse. In some cases, a number of changes can all cause the query optimizer to choose a different plan and lead to performance regression. These changes include changes in statistics, constraints, environment settings, query parameter bindings, and software upgrades. Regression is a major concern for high-performance applications.

With query plan management, you can control execution plans for a set of statements that you want to manage. You can do the following:

- Improve plan stability by forcing the optimizer to choose from a small number of known, good plans.
- Optimize plans centrally and then distribute the best plans globally.
- Identify indexes that aren't being used, and assess the impact of creating or dropping an index.
- Automatically detect a new minimum-cost plan generated by the optimizer.
- Try new optimizer features with less risk, because you can choose to approve only the plan changes that improve performance.

- [Function reference for Aurora PostgreSQL query plan management \(p. 1311\)](#)

## Turning on query plan management for Aurora PostgreSQL

Query plan management is available with the following Aurora PostgreSQL versions:

- All Aurora PostgreSQL 14 and 13 versions
- Aurora PostgreSQL version 12.4 and higher
- Aurora PostgreSQL version 11.6 and higher
- Aurora PostgreSQL version 10.5 and higher

Only users with the `rds_superuser` role can complete the following procedure. The `rds_superuser` is required for creating the `apg_plan_mgmt` extension and its `apg_plan_mgmt` role. Users must be granted the `apg_plan_mgmt` role to administer the `apg_plan_mgmt` extension.

### To enable query plan management

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Create a new instance-level parameter group to use for query plan management parameters. For more information, see [Creating a DB parameter group \(p. 228\)](#). Associate the new parameter group with the DB instances in which you want to use query plan management. For more information, see [Modify a DB instance in a DB cluster \(p. 249\)](#).
3. Create a new cluster-level parameter group to use for query plan management parameters. For more information, see [Creating a DB cluster parameter group \(p. 219\)](#). Associate the new cluster-level parameter group with the DB clusters in which you want to use query plan management. For more information, see [Modifying the DB cluster by using the console, CLI, and API \(p. 248\)](#).
4. Open your cluster-level parameter group and set the `rds.enable_plan_management` parameter to 1. For more information, see [Modifying parameters in a DB cluster parameter group \(p. 221\)](#).
5. Reboot your DB instance to enable this new setting.
6. Connect to your DB instance with a SQL client such as `psql`.
7. Create the `apg_plan_mgmt` extension for your DB instance. The following shows an example.

```
psql my-database
my-database=> CREATE EXTENSION apg_plan_mgmt;
```

If you create the `apg_plan_mgmt` extension in the `template1` default database, then the query plan management extension is available in each new database that you create.

You can disable query plan management at any time by turning off the `apg_plan_mgmt.use_plan_baselines` and `apg_plan_mgmt.capture_plan_baselines`:

```
my-database=> SET apg_plan_mgmt.use_plan_baselines = off;
my-database=> SET apg_plan_mgmt.capture_plan_baselines = off;
```

# Upgrading Aurora PostgreSQL query plan management

The latest version of query plan management is 2.0. If you installed an earlier version of query plan management, we strongly recommend that you upgrade to version 2.0. For version details, see [Extension versions for Amazon Aurora PostgreSQL \(p. 1415\)](#).

To upgrade, run the following commands at the cluster or DB instance level.

```
ALTER EXTENSION apg_plan_mgmt UPDATE TO '2.0';
SELECT apg_plan_mgmt.validate_plans('update_plan_hash');
SELECT apg_plan_mgmt.reload();
```

## Basics of Aurora PostgreSQL query plan management

You can manage any SELECT, INSERT, UPDATE, or DELETE statement with query plan management, regardless of how complex the statement is. Prepared, dynamic, embedded, and immediate-mode SQL statements are all supported. All PostgreSQL language features can be used, including partitioned tables, inheritance, row-level security, and recursive common table expressions (CTEs).

### Topics

- [Capturing an Aurora PostgreSQL query plan manually \(p. 1292\)](#)
- [Viewing captured plans \(p. 1292\)](#)
- [Working with managed statements and the SQL hash \(p. 1293\)](#)
- [Working with automatic plan capture \(p. 1294\)](#)

## Capturing an Aurora PostgreSQL query plan manually

To capture plans for specific statements, use the manual capture mode as in the following example.

```
/* Turn on manual capture */
SET apg_plan_mgmt.capture_plan_baselines = manual;
EXPLAIN SELECT COUNT(*) from pg_class;          -- capture the plan baseline
SET apg_plan_mgmt.capture_plan_baselines = off;   -- turn off capture
SET apg_plan_mgmt.use_plan_baselines =      true;  -- turn on plan usage
```

You can either execute SELECT, INSERT, UPDATE, or DELETE statements, or you can include the EXPLAIN statement as shown above. Use EXPLAIN to capture a plan without the overhead or potential side-effects of executing the statement. For more about manual capture, see [Manually capturing plans for specific SQL statements \(p. 1300\)](#). Note that query plan management doesn't save the plans for statements that refer to system tables such as pg\_class.

## Viewing captured plans

When EXPLAIN SELECT runs in the previous example, the optimizer saves the plan. To do so, it inserts a row into the apg\_plan\_mgmt.dba\_plans view and commits the plan in an autonomous transaction. You can see the contents of the apg\_plan\_mgmt.dba\_plans view if you've been granted the apg\_plan\_mgmt role. The following query displays some important columns of the dba\_plans view.

```
SELECT sql_hash, plan_hash, status, enabled, plan_outline, sql_text::varchar(40)
FROM apg_plan_mgmt.dba_plans
ORDER BY sql_text, plan_created;
```

Each row displayed represents a managed plan. The preceding example displays the following information.

- `sql_hash` – The ID of the managed statement that the plan is for.
- `plan_hash` – The ID of the managed plan.
- `status` – The status of the plan. The optimizer can run an approved plan.
- `enabled` – A value that indicates whether the plan is enabled for use or disabled and not for use.
- `plan_outline` – Details of the managed plan.

For more about the `apg_plan_mgmt.dba_plans` view, see [Examining Aurora PostgreSQL query plans in the dba\\_plans view \(p. 1297\)](#).

## Working with managed statements and the SQL hash

A *managed statement* is a SQL statement captured by the optimizer under query plan management. You specify which SQL statements to capture as managed statements using either manual or automatic capture:

- For manual capture, you provide the specific statements to the optimizer as shown in the previous example.
- For automatic capture, the optimizer captures plans for statements that run multiple times. Automatic capture is shown in a later example.

In the `apg_plan_mgmt.dba_plans` view, you can identify a managed statement with a SQL hash value. The SQL hash is calculated on a normalized representation of the SQL statement that removes some differences such as the literal values. Using normalization means that when multiple SQL statements differ only in their literal or parameter values, they are represented by the same SQL hash in the `apg_plan_mgmt.dba_plans` view. Therefore, there can be multiple plans for the same SQL hash where each plan is optimal under different conditions.

When the optimizer processes any SQL statement, it uses the following rules to create the normalized SQL statement:

- Removes any leading block comment
- Removes the EXPLAIN keyword and EXPLAIN options, if present
- Removes trailing spaces
- Removes all literals
- Preserves space and case for readability

For example, take the following statement.

```
/*Leading comment*/ EXPLAIN SELECT /* Query 1 */ * FROM t WHERE x > 7 AND y = 1;
```

The optimizer normalizes this statement as the following.

```
SELECT /* Query 1 */ * FROM t WHERE x > CONST AND y = CONST;
```

## Working with automatic plan capture

Use automatic plan capture if you want to capture plans for all SQL statements in your application, or if you can't use manual capture. With automatic plan capture, the optimizer captures plans for statements that run at least two times. To use automatic plan capture, do the following.

1. Create a custom DB parameter group based on the default DB parameter group for the version of Aurora PostgreSQL that you're running.
2. Edit the custom DB parameter group, by changing the `apg_plan_mgmt.capture_plan_baselines` setting to `automatic`.
3. Save your customized DB parameter group.
4. Apply your custom DB parameter group to an Aurora DB instance that is already running as follows:
  - Choose your Aurora PostgreSQL DB instance from the list in the navigation pane, and then choose **Modify**.
  - In the **Additional configuration** section of the Modify DB instance page, for the **DB parameter group**, choose your custom DB parameter group.
  - Choose **Continue**. Confirm the Summary of modifications and choose **Apply immediately**.
  - Choose **Modify DB instance** to apply your custom DB parameter group.

You can also use your custom DB parameter group when you create a new Aurora PostgreSQL DB instance. For more information about parameter groups, see [Modifying parameters in a DB parameter group \(p. 231\)](#).

As your application runs, the optimizer captures plans for any statement that runs more than once. The optimizer always sets the status of a managed statement's first captured plan to approved. A managed statement's set of approved plans is known as its *plan baseline*.

As your application continues to run, the optimizer might find additional plans for the managed statements. The optimizer sets additional captured plans to a status of unapproved.

The set of all captured plans for a managed statement is known as the *plan history*. Later, you can decide if the unapproved plans perform well and change them to Approved, Rejected, or Preferred by using the `apg_plan_mgmt.evolve_plan_baselines` function or the `apg_plan_mgmt.set_plan_status` function.

To turn off automatic plan capture, set `apg_plan_mgmt.capture_plan_baselines` to `off` in the parameter group for the DB instance. Follow the same general process as outlined above, modifying your custom DB parameter group value for `apg_plan_mgmt.capture_plan_baselines` and then applying the custom DB parameter group to your Aurora DB instance.

For more about plan capture, see [Capturing Aurora PostgreSQL execution plans \(p. 1299\)](#).

## Validating plans

Managed plans can become invalid ("stale") when objects that they depend on are removed, such as an index. To find and delete all plans that are stale, use the `apg_plan_mgmt.validate_plans` function.

```
SELECT apg_plan_mgmt.validate_plans('delete');
```

For more information, see [Validating plans \(p. 1305\)](#).

## Approving new plans that improve performance

While using your managed plans, you can verify whether newer, lower-cost plans discovered by the optimizer are faster than the minimum-cost plan already in the plan baseline.

To do the performance comparison and optionally approve the faster plans, call the `apg_plan_mgmt.evolve_plan_baselines` function.

The following example automatically approves any unapproved plan that is enabled and faster by at least 10 percent than the minimum-cost plan in the plan baseline.

```
SELECT apg_plan_mgmt.evolve_plan_baselines(
    sql_hash,
    plan_hash,
    1.1,
    'approve'
)
FROM apg_plan_mgmt.dba_plans
WHERE status = 'Unapproved' AND enabled = true;
```

When the `apg_plan_mgmt.evolve_plan_baselines` function runs, it collects performance statistics and saves them in the `apg_plan_mgmt.dba_plans` view in the columns `planning_time_ms`, `execution_time_ms`, `cardinality_error`, `total_time_benefit_ms`, and `execution_time_benefit_ms`. The `apg_plan_mgmt.evolve_plan_baselines` function also updates the columns `last_verified` or `last_validated` timestamps, in which you can see the most recent time the performance statistics were collected.

```
SELECT sql_hash, plan_hash, status, last_verified, sql_text::varchar(40)
FROM apg_plan_mgmt.dba_plans
ORDER BY last_verified DESC; -- value updated by evolve_plan_baselines()
```

For more information about verifying plans, see [Evaluating plan performance \(p. 1304\)](#).

## Deleting plans

The optimizer deletes plans automatically if they have not been executed or chosen as the minimum-cost plan for the plan retention period. By default, the plan retention period is 32 days. To change the plan retention period, set the `apg_plan_mgmt.plan_retention_period` parameter.

You can also review the contents of the `apg_plan_mgmt.dba_plans` view and delete any plans you don't want by using the `apg_plan_mgmt.delete_plan` function. For more information, see [Deleting plans \(p. 1307\)](#).

# Best practices for Aurora PostgreSQL query plan management

Query plan management lets you control how and when query execution plans change. As a DBA, your main goals when using QPM include preventing regressions when there are changes to your database, and controlling when the optimizer can use a new plan. In the following, you can find some recommended best practices for using query plan management. Proactive and reactive plan management approaches differ in how and when new plans get approved for use.

## Proactive plan management to help prevent performance regression

To prevent plan performance regressions from occurring, you gather evidence and then manually approve new plans after you have verified that they are faster.

1. In a development environment, identify the SQL statements that have the greatest impact on performance or system throughput. Then capture the plans for these statements as described in [Manually capturing plans for specific SQL statements \(p. 1300\)](#) and [Automatically capturing plans \(p. 1300\)](#).

2. Export the captured plans from the development environment and import them into the production environment. For more information, see [Exporting and importing plans \(p. 1307\)](#).
3. In production, run your application and enforce the use of approved managed plans. For more information, see [Using Aurora PostgreSQL managed plans \(p. 1301\)](#). While the application runs, also add new plans as the optimizer discovers them. For more information, see [Automatically capturing plans \(p. 1300\)](#).
4. Analyze the unapproved plans and approve those that perform well. For more information, see [Evaluating plan performance \(p. 1304\)](#).
5. While your application continues to run, the optimizer begins to use the new plans as appropriate.

## Ensuring plan stability after a major version upgrade

Each major version of PostgreSQL includes enhancements and changes to the query optimizer that are designed to improve performance. However, your workload may include queries that result in a worse performing plan in the new version. You can use the query plan manager to ensure plan stability after a major version upgrade.

The optimizer always uses the minimum cost plan, even if more than one approved plans exist. That means that you can have multiple approved plans for each statement in your workload prior to upgrading. After the upgrade, the optimizer will use only one of the approved plans, even if the changes in the new major version might lead to a different plan being created. After upgrading, you can use the `evolve_plan_baselines` function to compare plan performance before and after the upgrade using your query parameter bindings. The following steps assume that you have been using approved managed plans in your production environment, as detailed in [Using Aurora PostgreSQL managed plans \(p. 1301\)](#).

1. Before upgrading, run your application with the query plan manager running. While the application runs, add new plans as the optimizer discovers them. For more information, see [Automatically capturing plans \(p. 1300\)](#).
2. Evaluate each plan's performance. For more information, see [Evaluating plan performance \(p. 1304\)](#).
3. After upgrading, analyze your approved plans again using the `evolve_plan_baselines` function. Compare performance before and after using your query parameter bindings. If the new plan is fast, you can add it to your approved plans. If it's faster than another plan for the same parameter bindings, then you can mark the slower plan as Rejected.

For more information, see [Approving better plans \(p. 1304\)](#). For reference information about this function, see [apg\\_plan\\_mgmt.evolve\\_plan\\_baselines \(p. 1312\)](#).

For more information, see [Ensuring consistent performance after major version upgrades with Amazon Aurora PostgreSQL-Compatible Edition Query Plan Management](#).

## Reactive plan management to detect and repair performance regressions

By monitoring your application as it runs, you can detect plans that cause performance regressions. When you detect regressions, you manually reject or fix the bad plans by following these steps:

1. While your application runs, enforce the use of managed plans and automatically add newly discovered plans as unapproved. For more information, see [Using Aurora PostgreSQL managed plans \(p. 1301\)](#) and [Automatically capturing plans \(p. 1300\)](#).
2. Monitor your running application for performance regressions.
3. When you discover a plan regression, set the plan's status to `rejected`. The next time the optimizer runs the SQL statement, it automatically ignores the rejected plan and uses a different approved plan instead. For more information, see [Rejecting or disabling slower plans \(p. 1305\)](#).

In some cases, you might prefer to fix a bad plan rather than reject, disable, or delete it. Use the `pg_hint_plan` extension to experiment with improving a plan. With `pg_hint_plan`, you use special comments to tell the optimizer to override how it normally creates a plan. For more information, see [Fixing plans using pg\\_hint\\_plan \(p. 1306\)](#).

## Examining Aurora PostgreSQL query plans in the dba\_plans view

Query plan management provides SQL view for database administrators (DBAs) to use called `apg_plan_mgmt.dba_plans`. This one view contains the plan history for all of the databases in the DB instance.

This view contains the plan history for all of your managed statements. Each managed plan is identified by the combination of a SQL hash value and a plan hash value. With these identifiers, you can use tools such as Amazon RDS Performance Insights to track individual plan performance. For more information about Performance Insights, see [Using Amazon RDS performance insights](#).

### Note

Access to the `apg_plan_mgmt.dba_plans` view is restricted to users that hold the `apg_plan_mgmt` role.

### Listing managed plans

To list the managed plans, use a SELECT statement on the `apg_plan_mgmt.dba_plans` view. The following example displays some columns in the `dba_plans` view such as the `status`, which identifies the approved and unapproved plans.

```
SELECT sql_hash, plan_hash, status, enabled, stmt_name
FROM apg_plan_mgmt.dba_plans;

sql_hash | plan_hash | status | enabled | stmt_name
-----+-----+-----+-----+-----
1984047223 | 512153379 | Approved | t | rangequery
1984047223 | 512284451 | Unapproved | t | rangequery
(2 rows)
```

### Reference for the apg\_plan\_mgmt.dba\_plans view

The columns of plan information in the `apg_plan_mgmt.dba_plans` view include the following.

dba_plans column	Description
<code>cardinality_error</code>	A measure of the error between the estimated cardinality versus the actual cardinality. <i>Cardinality</i> is the number of table rows that the plan is to process. If the cardinality error is large, then it increases the likelihood that the plan isn't optimal. This column is populated by the <a href="#">apg_plan_mgmt.evolve_plan_baselines (p. 1312)</a> function.
<code>compatibility_level</code>	The feature level of the Aurora PostgreSQL optimizer.
<code>created_by</code>	The authenticated user ( <code>session_user</code> ) who created the plan.
<code>enabled</code>	An indicator of whether the plan is enabled or disabled. All plans are enabled by default. You can disable plans to prevent them.

dba_plans column	Description
	from being used by the optimizer. To modify this value, use the <a href="#">apg_plan_mgmt.set_plan_enabled (p. 1315)</a> function.
environment_variables	The PostgreSQL Grand Unified Configuration (GUC) parameters and values that the optimizer has overridden at the time the plan was captured.
estimated_startup_cost	The estimated optimizer setup cost before the optimizer delivers rows of a table.
estimated_total_cost	The estimated optimizer cost to deliver the final table row.
execution_time_benefit	The execution time benefit in milliseconds of enabling the plan. This column is populated by the <a href="#">apg_plan_mgmt.evolve_plan_baselines (p. 1312)</a> function.
execution_time_ms	The estimated time in milliseconds that the plan would run. This column is populated by the <a href="#">apg_plan_mgmt.evolve_plan_baselines (p. 1312)</a> function.
has_side_effects	A value that indicates that the SQL statement is a data manipulation language (DML) statement or a SELECT statement that contains a VOLATILE function.
last_used	This value is updated to the current date whenever the plan is either executed or when the plan is the query optimizer's minimum-cost plan. This value is stored in shared memory and periodically flushed to disk. To get the most up-to-date value, read the date from shared memory by calling the function <code>apg_plan_mgmt.plan_last_used(sql_hash, plan_hash)</code> instead of reading the <code>last_used</code> value. For additional information, see the <a href="#">apg_plan_mgmt.plan_retention_period (p. 1310)</a> parameter.
last_validated	The most recent date and time when it was verified that the plan could be recreated by either the <a href="#">apg_plan_mgmt.validate_plans (p. 1317)</a> function or the <a href="#">apg_plan_mgmt.evolve_plan_baselines (p. 1312)</a> function.
last_verified	The most recent date and time when a plan was verified to be the best-performing plan for the specified parameters by the <a href="#">apg_plan_mgmt.evolve_plan_baselines (p. 1312)</a> function.
origin	How the plan was captured with the <a href="#">apg_plan_mgmt.capture_plan_baselines (p. 1309)</a> parameter. Valid values include the following:  M – The plan was captured with manual plan capture.  A – The plan was captured with automatic plan capture.
param_list	The parameter values that were passed to the statement if this is a prepared statement.
plan_created	The date and time the plan that was created.
plan_hash	The plan identifier. The combination of <code>plan_hash</code> and <code>sql_hash</code> uniquely identifies a specific plan.
plan_outline	A representation of the plan that is used to recreate the actual execution plan, and that is database-independent. Operators in the tree correspond to operators that appear in the EXPLAIN output.
planning_time_ms	The actual time to run the planner, in milliseconds. This column is populated by the <a href="#">apg_plan_mgmt.evolve_plan_baselines (p. 1312)</a> function.

dba_plans column	Description
queryId	A statement hash, as calculated by the pg_stat_statements extension. This isn't a stable or database-independent identifier because it depends on object identifiers (OIDs).
sql_hash	A hash value of the SQL statement text, normalized with literals removed.
sql_text	The full text of the SQL statement.
status	<p>A plan's status, which determines how the optimizer uses a plan. Valid values include the following.</p> <ul style="list-style-type: none"> <li>Approved – A usable plan that the optimizer can choose to run. The optimizer runs the least-cost plan from a managed statement's set of approved plans (baseline). To reset a plan to approved, use the <a href="#">apg_plan_mgmt.evolve_plan_baselines (p. 1312)</a> function.</li> <li>Unapproved – A captured plan that you have not verified for use. For more information, see <a href="#">Evaluating plan performance (p. 1304)</a>.</li> <li>Rejected – A plan that the optimizer won't use. For more information, see <a href="#">Rejecting or disabling slower plans (p. 1305)</a>.</li> <li>Preferred – A plan that you have determined is a preferred plan to use for a managed statement.</li> </ul> <p>If the optimizer's minimum-cost plan isn't an approved or preferred plan, you can reduce plan enforcement overhead. To do so, make a subset of the approved plans Preferred. When the optimizer's minimum cost isn't an Approved plan, a Preferred plan is chosen before an Approved plan.</p> <p>To reset a plan to Preferred, use the <a href="#">apg_plan_mgmt.set_plan_status (p. 1315)</a> function.</p>
stmt_name	The name of the SQL statement within a PREPARE statement. This value is an empty string for an unnamed prepared statement. This value is NULL for a nonprepared statement.
total_time_benefit	<p>The total time benefit in milliseconds of enabling this plan. This value considers both planning time and execution time.</p> <p>If this value is negative, there is a disadvantage to enabling this plan. This column is populated by the <a href="#">apg_plan_mgmt.evolve_plan_baselines (p. 1312)</a> function.</p>

## Capturing Aurora PostgreSQL execution plans

You can capture execution plans for specific SQL statements by using manual plan capture. Alternatively, you can capture all (or the slowest) plans that are executed two or more times as your application runs by using automatic plan capture.

When capturing plans, the optimizer sets the status of a managed statement's first captured plan to approved. The optimizer sets the status of any additional plans captured for a managed statement to unapproved. However, more than one plan might occasionally be saved with the approved status. This can happen when multiple plans are created for a statement in parallel and before the first plan for the statement is committed.

To control the maximum number of plans that can be captured and stored in the dba\_plans view, set the `apg_plan_mgmt.max_plans` parameter in your DB instance-level parameter group. A change to

the `apg_plan_mgmt.max_plans` parameter requires a DB instance reboot for a new value to take effect. For more information, see the [apg\\_plan\\_mgmt.max\\_plans \(p. 1310\)](#) parameter.

### Topics

- [Manually capturing plans for specific SQL statements \(p. 1300\)](#)
- [Automatically capturing plans \(p. 1300\)](#)

## Manually capturing plans for specific SQL statements

If you have a known set of SQL statements to manage, put the statements into a SQL script file and then manually capture plans. The following shows a `psql` example of how to capture query plans manually for a set of SQL statements.

```
psql> SET apg_plan_mgmt.capture_plan_baselines = manual;
psql> \i my-statements.sql
psql> SET apg_plan_mgmt.capture_plan_baselines = off;
```

After capturing a plan for each SQL statement, the optimizer adds a new row to the `apg_plan_mgmt.dba_plans` view.

We recommend that you use either EXPLAIN or EXPLAIN EXECUTE statements in the SQL script file. Make sure that you include enough variations in parameter values to capture all the plans of interest.

If you know of a better plan than the optimizer's minimum cost plan, you might be able to force the optimizer to use the better plan. To do so, specify one or more optimizer hints. For more information, see [Fixing plans using pg\\_hint\\_plan \(p. 1306\)](#). To compare the performance of the unapproved and approved plans and approve, reject, or delete them, see [Evaluating plan performance \(p. 1304\)](#).

## Automatically capturing plans

Use automatic plan capture for situations such as the following:

- You don't know the specific SQL statements that you want to manage.
- You have hundreds or thousands of SQL statements to manage.
- Your application uses a client API. For example, JDBC uses unnamed prepared statements or bulk-mode statements that can't be expressed in `psql`.

### To capture plans automatically

1. Turn on automatic plan capture by setting `apg_plan_mgmt.capture_plan_baselines` to `automatic` in the DB instance-level parameter group. For more information, see [Modifying parameters in a DB parameter group \(p. 231\)](#).
2. Reboot your DB instance.
3. As the application runs, the optimizer captures plans for each SQL statement that runs at least twice.

As the application runs with default query plan management parameter settings, the optimizer captures plans for each SQL statement that runs at least twice. Capturing all plans while using the defaults has very little run-time overhead and can be enabled in production.

### To turn off automatic plan capture

- Set the `apg_plan_mgmt.capture_plan_baselines` parameter to `off` from the DB instance-level parameter group.

To measure the performance of the unapproved plans and approve, reject, or delete them, see [Evaluating plan performance \(p. 1304\)](#).

## Using Aurora PostgreSQL managed plans

To get the optimizer to use captured plans for your managed statements, set the parameter `apg_plan_mgmt.use_plan_baselines` to `true`. The following is a local instance example.

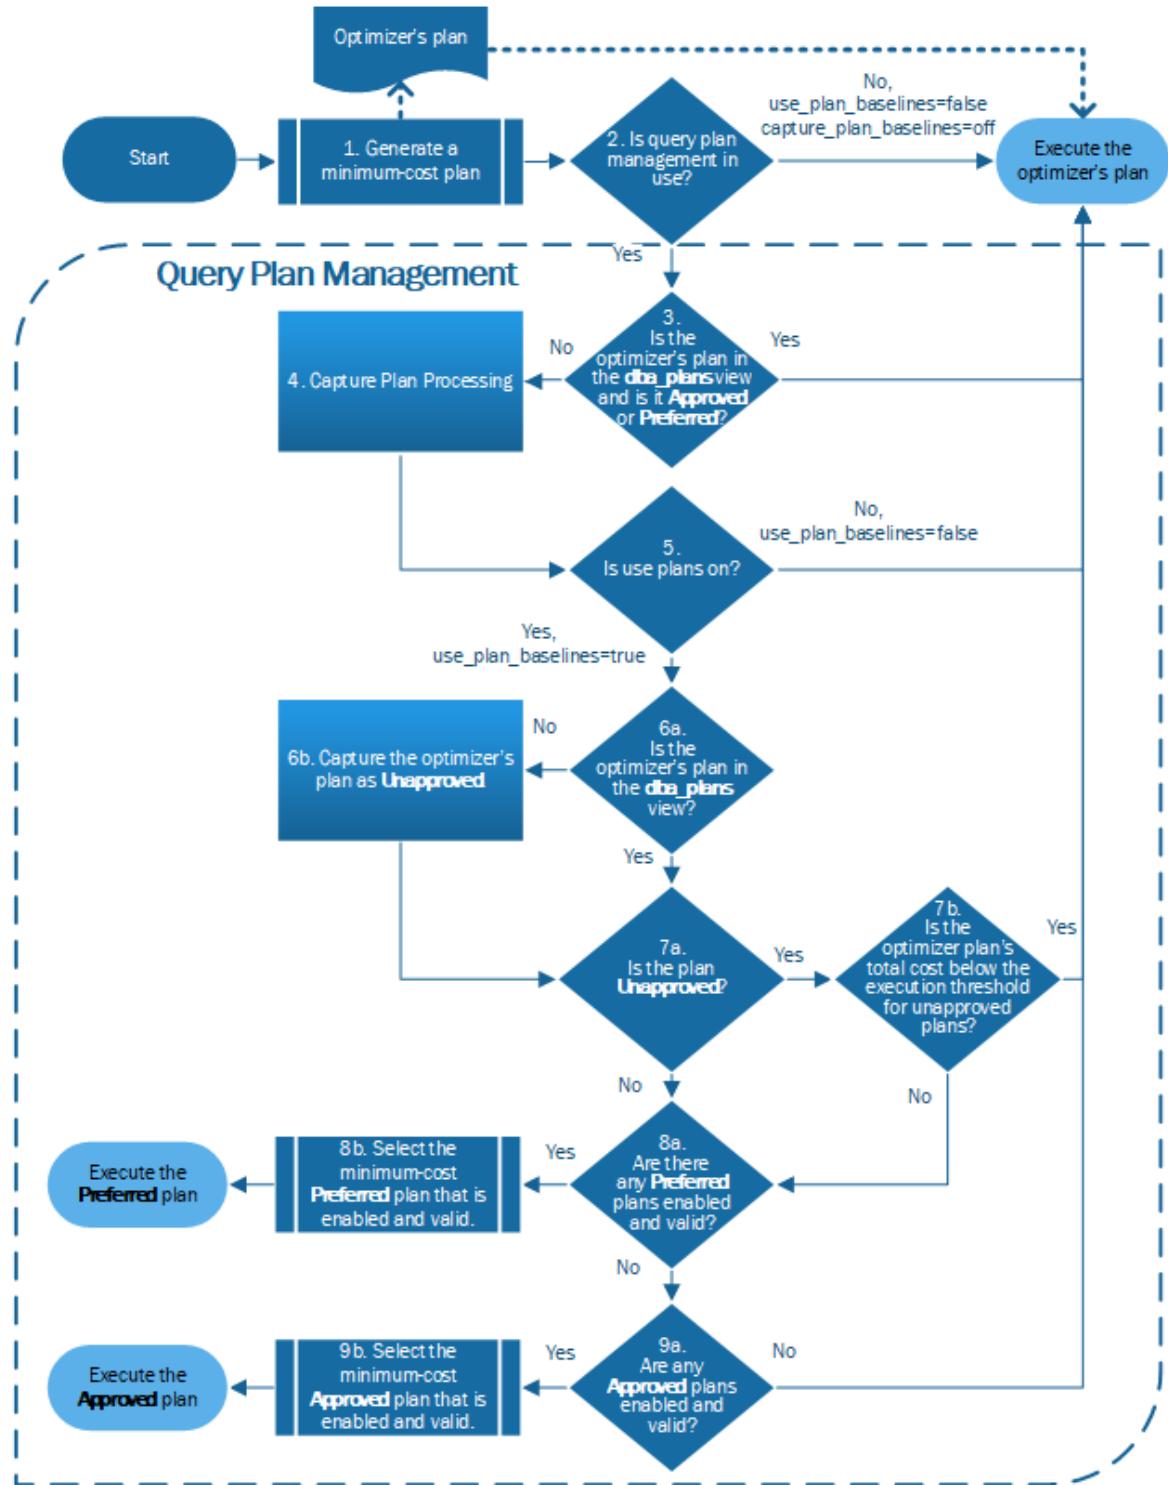

```
SET apg_plan_mgmt.use_plan_baselines = true;
```

While the application runs, this setting causes the optimizer to use the minimum-cost, preferred, or approved plan that is valid and enabled, for each managed statement.

### How the optimizer chooses which plan to run

The cost of an execution plan is an estimate that the optimizer makes to compare different plans. Optimizer cost is a function of several factors that include the CPU and I/O operations that the plan uses. For more information about PostgreSQL query planner costs, see the [PostgreSQL documentation on query planning](#).

The following flowchart shows how the query plan management optimizer chooses which plan to run.

The flow is as follows:

1. When the optimizer processes every SQL statement, it generates a minimum-cost plan.
2. Without query plan management, the optimizer simply runs its generated plan. The optimizer uses query plan management if you set one or both of the following parameter settings:

- `apg_plan_mgmt.capture_plan_baselines` to manual or automatic
  - `apg_plan_mgmt.use_plan_baselines` to true
3. The optimizer immediately runs the generated plan if the following are both true:
- The optimizer's plan is already in the `apg_plan_mgmt.dba_plans` view for the SQL statement.
  - The plan's status is either approved or preferred.
4. The optimizer goes through the capture plan processing if the parameter `apg_plan_mgmt.capture_plan_baselines` is manual or automatic.

For details on how the optimizer captures plans, see [Capturing Aurora PostgreSQL execution plans \(p. 1299\)](#).

5. The optimizer runs the generated plan if `apg_plan_mgmt.use_plan_baselines` is false.
6. If the optimizer's plan isn't in the `apg_plan_mgmt.dba_plans` view, the optimizer captures the plan as a new unapproved plan.
7. The optimizer runs the generated plan if the following are both true:
- The optimizer's plan isn't a rejected or disabled plan.
  - The plan's total cost is less than the unapproved execution plan threshold.

The optimizer doesn't run disabled plans or any plans that have the rejected status. In most cases, the optimizer doesn't execute unapproved plans. However, the optimizer runs an unapproved plan if you set a value for the parameter `apg_plan_mgmt.unapproved_plan_execution_threshold` and the plan's total cost is less than the threshold. For more information, see the [apg\\_plan\\_mgmt.unapproved\\_plan\\_execution\\_threshold \(p. 1310\)](#) parameter.

8. If the managed statement has any enabled and valid preferred plans, the optimizer runs the minimum-cost one.

A valid plan is one that the optimizer can run. Managed plans can become invalid for various reasons. For example, plans become invalid when objects that they depend on are removed, such as an index or a partition of a partitioned table.

9. The optimizer determines the minimum-cost plan from the managed statement's approved plans that are both enabled and valid. The optimizer then runs the minimum-cost approved plan.

## Analyzing which plan the optimizer will use

When the `apg_plan_mgmt.use_plan_baselines` parameter is set to true, you can use EXPLAIN ANALYZE SQL statements to cause the optimizer to show the plan it would use if it were to run the statement. The following is an example.

```
EXPLAIN ANALYZE EXECUTE rangeQuery (1,10000);
```

```
QUERY PLAN
-----
Aggregate  (cost=393.29..393.30 rows=1 width=8) (actual time=7.251..7.251 rows=1 loops=1)
    -> Index Only Scan using t1_pkey on t1 t  (cost=0.29..368.29 rows=10000 width=0)
        (actual time=0.061..4.859 rows=10000 loops=1)
Index Cond: ((id >= 1) AND (id <= 10000))
    Heap Fetches: 10000
Planning time: 1.408 ms
Execution time: 7.291 ms
Note: An Approved plan was used instead of the minimum cost plan.
SQL Hash: 1984047223, Plan Hash: 512153379
```

The optimizer indicates which plan it will run, but notice that in this example that it found a lower-cost plan. In this case, you capture this new minimum cost plan by turning on automatic plan capture as described in [Automatically capturing plans \(p. 1300\)](#).

The optimizer captures new plans as Unapproved. Use the `apg_plan_mgmt.evolve_plan_baselines` function to compare plans and change them to approved, rejected, or disabled. For more information, see [Evaluating plan performance \(p. 1304\)](#).

## Maintaining Aurora PostgreSQL execution plans

Query plan management provides techniques and functions to add, maintain, and improve execution plans.

### Topics

- [Evaluating plan performance \(p. 1304\)](#)
- [Validating plans \(p. 1305\)](#)
- [Fixing plans using pg\\_hint\\_plan \(p. 1306\)](#)
- [Deleting plans \(p. 1307\)](#)
- [Exporting and importing plans \(p. 1307\)](#)

## Evaluating plan performance

After the optimizer captures plans as unapproved, use the `apg_plan_mgmt.evolve_plan_baselines` function to compare plans based on their actual performance. Depending on the outcome of your performance experiments, you can change a plan's status from unapproved to either approved or rejected. You can instead decide to use the `apg_plan_mgmt.evolve_plan_baselines` function to temporarily disable a plan if it does not meet your requirements.

### Topics

- [Approving better plans \(p. 1304\)](#)
- [Rejecting or disabling slower plans \(p. 1305\)](#)

## Approving better plans

The following example demonstrates how to change the status of managed plans to approved using the `apg_plan_mgmt.evolve_plan_baselines` function.

```
SELECT apg_plan_mgmt.evolve_plan_baselines (
    sql_hash,
    plan_hash,
    min_speedup_factor := 1.0,
    action := 'approve'
)
FROM apg_plan_mgmt.dba_plans WHERE status = 'Unapproved';
```

```
NOTICE:      rangequery (1,10000)
NOTICE:      Baseline   [ Planning time 0.761 ms, Execution time 13.261 ms]
NOTICE:      Baseline+1 [ Planning time 0.204 ms, Execution time 8.956 ms]
NOTICE:      Total time benefit: 4.862 ms, Execution time benefit: 4.305 ms
NOTICE:      Unapproved -> Approved
evolve_plan_baselines
-----
0
(1 row)
```

The output shows a performance report for the `rangequery` statement with parameter bindings of 1 and 10,000. The new unapproved plan (`Baseline+1`) is better than the best previously approved plan (`Baseline`). To confirm that the new plan is now `Approved`, check the `apg_plan_mgmt.dba_plans` view.

```
SELECT sql_hash, plan_hash, status, enabled, stmt_name
FROM apg_plan_mgmt.dba_plans;
```

sql_hash	plan_hash	status	enabled	stmt_name
1984047223	512153379	Approved	t	rangequery
1984047223	512284451	Approved	t	rangequery

(2 rows)

The managed plan now includes two approved plans that are the statement's plan baseline. You can also call the `apg_plan_mgmt.set_plan_status` function to directly set a plan's status field to '`Approved`', '`Rejected`', '`Unapproved`', or '`Preferred`'.

## Rejecting or disabling slower plans

To reject or disable plans, pass '`reject`' or '`disable`' as the action parameter to the `apg_plan_mgmt.evolve_plan_baselines` function. This example disables any captured `Unapproved` plan that is slower by at least 10 percent than the best `Approved` plan for the statement.

```
SELECT apg_plan_mgmt.evolve_plan_baselines(
    sql_hash, -- The managed statement ID
    plan_hash, -- The plan ID
    1.1, -- number of times faster the plan must be
    'disable' -- The action to take. This sets the enabled field to false.
)
FROM apg_plan_mgmt.dba_plans
WHERE status = 'Unapproved' AND -- plan is Unapproved
origin = 'Automatic'; -- plan was auto-captured
```

You can also directly set a plan to `Rejected` or `Disabled`. To directly set a plan's `enabled` field to `true` or `false`, call the `apg_plan_mgmt.set_plan_enabled` function. To directly set a plan's `status` field to '`Approved`', '`Rejected`', '`Unapproved`', or '`Preferred`', call the `apg_plan_mgmt.set_plan_status` function.

## Validating plans

Use the `apg_plan_mgmt.validate_plans` function to delete or disable plans that are invalid.

Plans can become invalid or stale when objects that they depend on are removed, such as an index or a table. However, a plan might be invalid only temporarily if the removed object gets recreated. If an invalid plan can become valid later, you might prefer to disable an invalid plan or do nothing rather than delete it.

To find and delete all plans that are invalid and haven't been used in the past week, use the `apg_plan_mgmt.validate_plans` function as follows.

```
SELECT apg_plan_mgmt.validate_plans(sql_hash, plan_hash, 'delete')
FROM apg_plan_mgmt.dba_plans
WHERE last_used < (current_date - interval '7 days');
```

To enable or disable a plan directly, use the `apg_plan_mgmt.set_plan_enabled` function.

## Fixing plans using pg\_hint\_plan

The query optimizer is well-designed to find an optimal plan for all statements, and in most cases the optimizer finds a good plan. However, occasionally you might know that a much better plan exists than that generated by the optimizer. Two recommended ways to get the optimizer to generate a desired plan include using the `pg_hint_plan` extension or setting Grand Unified Configuration (GUC) variables in PostgreSQL:

- `pg_hint_plan` extension – Specify a "hint" to modify how the planner works by using PostgreSQL's `pg_hint_plan` extension. To install and learn more about how to use the `pg_hint_plan` extension, see the [pg\\_hint\\_plan documentation](#).
- GUC variables – Override one or more cost model parameters or other optimizer parameters, such as the `fromCollapse_limit` or `GEOO_threshold`.

When you use one of these techniques to force the query optimizer to use a plan, you can also use query plan management to capture and enforce use of the new plan.

You can use the `pg_hint_plan` extension to change the join order, the join methods, or the access paths for a SQL statement. You use a SQL comment with special `pg_hint_plan` syntax to modify how the optimizer creates a plan. For example, assume the problem SQL statement has a two-way join.

```
SELECT *
FROM t1, t2
WHERE t1.id = t2.id;
```

Then suppose that the optimizer chooses the join order (`t1, t2`), but we know that the join order (`t2, t1`) is faster. The following hint forces the optimizer to use the faster join order, (`t2, t1`). Include EXPLAIN so that the optimizer generates a plan for the SQL statement but does not run the statement. (Output not shown.)

```
/*+ Leading ((t2 t1)) */ EXPLAIN SELECT *
FROM t1, t2
WHERE t1.id = t2.id;
```

The following steps show how to use `pg_hint_plan`.

### To modify the optimizer's generated plan and capture the plan using pg\_hint\_plan

1. Turn on the manual capture mode.

```
SET apg_plan_mgmt.capture_plan_baselines = manual;
```

2. Specify a hint for the SQL statement of interest.

```
/*+ Leading ((t2 t1)) */ EXPLAIN SELECT *
FROM t1, t2
WHERE t1.id = t2.id;
```

After this runs, the optimizer captures the plan in the `apg_plan_mgmt.dba_plans` view. The captured plan doesn't include the special `pg_hint_plan` comment syntax because query plan management normalizes the statement by removing leading comments.

3. View the managed plans by using the `apg_plan_mgmt.dba_plans` view.

```
SELECT sql_hash, plan_hash, status, sql_text, plan_outline
FROM apg_plan_mgmt.dba_plans;
```

4. Set the status of the plan to `Preferred`. Doing so makes sure that the optimizer chooses to run it, instead of selecting from the set of approved plans, when the minimum-cost plan isn't already `Approved` or `Preferred`.

```
SELECT apg_plan_mgmt.set_plan_status(sql_hash, plan_hash, 'preferred' );
```

5. Turn off manual plan capture and enforce the use of managed plans.

```
SET apg_plan_mgmt.capture_plan_baselines = false;
SET apg_plan_mgmt.use_plan_baselines = true;
```

Now, when the original SQL statement runs, the optimizer chooses either an `Approved` or `Preferred` plan. If the minimum-cost plan isn't `Approved` or `Preferred`, then the optimizer chooses the `Preferred` plan.

## Deleting plans

Delete plans that have not been used for a long time or that are no longer relevant. Each plan has a `last_used` date that the optimizer updates each time it executes a plan or picks it as the minimum-cost plan for a statement. Use the `last_used` date to determine if a plan has been used recently and is still relevant.

For example, you can use the `apg_plan_mgmt.delete_plan` function as follows. Doing this deletes all plans that haven't been chosen as the minimum-cost plan or haven't run in at least 31 days. However, this example doesn't delete plans that have been explicitly rejected.

```
SELECT SUM(apg_plan_mgmt.delete_plan(sql_hash, plan_hash))
FROM apg_plan_mgmt.dba_plans
WHERE last_used < (current_date - interval '31 days')
AND status <> 'Rejected';
```

To delete any plan that is no longer valid and that you expect not to become valid again, use the `apg_plan_mgmt.validate_plans` function. For more information, see [Validating plans \(p. 1305\)](#).

You can implement your own policy for deleting plans. Plans are automatically deleted when the current date `last_used` is greater than the value of the `apg_plan_mgmt.plan_retention_period` parameter, which defaults to 32 days. You can specify a longer interval, or you can implement your own plan retention policy by calling the `delete_plan` function directly. The `last_used` date is the most recent date that either the optimizer chose a plan as the minimum cost plan or that the plan was executed.

### Important

If you don't clean up plans, you might eventually run out of shared memory that's set aside for query plan management. To control how much memory is available for managed plans, use the `apg_plan_mgmt.max_plans` parameter. Set this parameter in your DB instance-level parameter group and reboot your DB instance for changes to take effect. For more information, see the [apg\\_plan\\_mgmt.max\\_plans \(p. 1310\)](#) parameter.

## Exporting and importing plans

You can export your managed plans and import them into another DB instance.

### To export managed plans

An authorized user can copy any subset of the `apg_plan_mgmt.plans` table to another table, and then save it using the `pg_dump` command. The following is an example.

```
CREATE TABLE plans_copy AS SELECT *  
FROM apg_plan_mgmt.plans [ WHERE predicates ] ;
```

```
% pg_dump --table apg_plan_mgmt.plans_copy -Ft mysourcedatabase > plans_copy.tar
```

```
DROP TABLE apg_plan_mgmt.plans_copy;
```

### To import managed plans

1. Copy the .tar file of the exported managed plans to the system where the plans are to be restored.
2. Use the `pg_restore` command to copy the tar file into a new table.

```
% pg_restore --dbname mytargetdatabase -Ft plans_copy.tar
```

3. Merge the `plans_copy` table with the `apg_plan_mgmt.plans` table, as shown in the following example.

#### Note

In some cases, you might dump from one version of the `apg_plan_mgmt` extension and restore into a different version. In these cases, the columns in the `plans` table might be different. If so, name the columns explicitly instead of using `SELECT *`.

```
INSERT INTO apg_plan_mgmt.plans SELECT * FROM plans_copy  
ON CONFLICT ON CONSTRAINT plans_pkey  
DO UPDATE SET  
status = EXCLUDED.status,  
enabled = EXCLUDED.enabled,  
-- Save the most recent last_used date  
  
last_used = CASE WHEN EXCLUDED.last_used > plans.last_used  
THEN EXCLUDED.last_used ELSE plans.last_used END,  
-- Save statistics gathered by evolve_plan_baselines, if it ran:  
  
estimated_startup_cost = EXCLUDED.estimated_startup_cost,  
estimated_total_cost = EXCLUDED.estimated_total_cost,  
planning_time_ms = EXCLUDED.planning_time_ms,  
execution_time_ms = EXCLUDED.execution_time_ms,  
total_time_benefit_ms = EXCLUDED.total_time_benefit_ms,  
execution_time_benefit_ms = EXCLUDED.execution_time_benefit_ms;
```

4. Reload the managed plans into shared memory and remove the temporary plans table.

```
SELECT apg_plan_mgmt.reload(); -- refresh shared memory  
DROP TABLE plans_copy;
```

## Parameter reference for Aurora PostgreSQL query plan management

You can set your preferences for the `apg_plan_mgmt` extension by using the parameters listed in this section. These are available in the custom DB cluster parameter and the DB parameter group associated with your Aurora PostgreSQL DB cluster. These parameters control the behavior of the query plan management feature and how it affects the optimizer. For information about setting up query plan management, see [Turning on query plan management for Aurora PostgreSQL \(p. 1291\)](#). Changing the parameters following has no effect if the `apg_plan_mgmt` extension isn't set up as detailed in

that section. For information about modifying parameters, see [Modifying parameters in a DB cluster parameter group \(p. 221\)](#) and [Working with DB parameter groups \(p. 228\)](#).

#### Parameters

- [apg\\_plan\\_mgmt.capture\\_plan\\_baselines \(p. 1309\)](#)
- [apg\\_plan\\_mgmt.max\\_databases \(p. 1309\)](#)
- [apg\\_plan\\_mgmt.max\\_plans \(p. 1310\)](#)
- [apg\\_plan\\_mgmt.plan\\_retention\\_period \(p. 1310\)](#)
- [apg\\_plan\\_mgmt.unapproved\\_plan\\_execution\\_threshold \(p. 1310\)](#)
- [apg\\_plan\\_mgmt.use\\_plan\\_baselines \(p. 1311\)](#)

## apg\_plan\_mgmt.capture\_plan\_baselines

Captures query execution plans generated by the optimizer for each SQL statement and stores them in the `dba_plans` view. By default, the maximum number of plans that can be stored is 10,000 as specified by the `apg_plan_mgmt.max_plans` parameter. For reference information, see [apg\\_plan\\_mgmt.max\\_plans \(p. 1310\)](#).

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter doesn't require a reboot.

Default	Allowed values	Description
off	automatic	Turns on plan capture for all databases on the DB instance. Collects a plan for each SQL statement that runs two or more times. Use this setting for large or evolving workloads to provide plan stability.
	manual	Turns on plan capture for subsequent statements only, until you turn it off again. Using this setting lets you capture query execution plans for specific critical SQL statements only or for known problematic queries.
	off	Turns off plan capture.

For more information, see [Capturing Aurora PostgreSQL execution plans \(p. 1299\)](#).

## apg\_plan\_mgmt.max\_databases

Specifies the maximum number of databases on your Aurora PostgreSQL DB cluster's Writer instance that can use query plan management. By default, up to 10 databases can use query plan management. If you have more than 10 databases on the instance, you can change the value of this setting. To find out how many databases are on a given instance, connect to the instance using `psql`. Then, use the `psql` metacommand, `\l`, to list the databases.

Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

Default	Allowed values	Description
10	10-2147483647	Maximum number of databases that can use query plan management on the instance.

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group.

## apg\_plan\_mgmt.max\_plans

Sets the maximum number of SQL statements that the query plan manager can maintain in the `apg_plan_mgmt.dba_plans` view. We recommend setting this parameter to 10000 or higher for all Aurora PostgreSQL versions.

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

Default	Allowed values	Description
10000	10-2147483647	Maximum number of plans that can be stored in the <code>apg_plan_mgmt.dba_plans</code> view.  Default for Aurora PostgreSQL version 10 and older versions is 1000.

For more information, see [Examining Aurora PostgreSQL query plans in the dba\\_plans view \(p. 1297\)](#).

## apg\_plan\_mgmt.plan\_retention\_period

Specifies the number of days to keep plans in the `apg_plan_mgmt.dba_plans` view, after which they're automatically deleted. By default, a plan is deleted when 32 days have elapsed since the plan was last used (the `last_used` column in the `apg_plan_mgmt.dba_plans` view). You can change this setting to any number, 32 and over.

Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

Default	Allowed values	Description
32	32-2147483647	Maximum number of days since a plan was last used before it's deleted.

For more information, see [Examining Aurora PostgreSQL query plans in the dba\\_plans view \(p. 1297\)](#).

## apg\_plan\_mgmt.unapproved\_plan\_execution\_threshold

Specifies a threshold below which an Unapproved plan can be used by the optimizer. By default, the optimizer doesn't run Unapproved plans. If you have an Unapproved plan that you suspect might be better than an Approved plan, you can use this parameter to sidestep the optimizer's default behavior. The value of this parameter represents a cost estimate for running a given plan. If an Unapproved plan is below that estimated cost, the optimizer uses it for the SQL statement. You can see captured plans and their status (Approved, Unapproved) in the `dba_plans` view. To learn more, see [Examining Aurora PostgreSQL query plans in the dba\\_plans view \(p. 1297\)](#).

Changing the value of this parameter doesn't require a reboot.

Default	Allowed values	Description
0	0-2147483647	Estimated plan cost below which an Unapproved plan is used.

For more information, see [Using Aurora PostgreSQL managed plans \(p. 1301\)](#).

## apg\_plan\_mgmt.use\_plan\_baselines

Specifies that the optimizer should use one of the Approved plans captured and stored in the `apg_plan_mgmt.dba_plans` view. By default, this parameter is off (false), causing the optimizer to use the minimum-cost plan that it generates without any further assessment. Turning this parameter on (setting it to true) forces the optimizer to choose a query execution plan for the statement from its plan baseline. For more information, see [Using Aurora PostgreSQL managed plans \(p. 1301\)](#). To find an image detailing this process, see [How the optimizer chooses which plan to run \(p. 1301\)](#).

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter doesn't require a reboot.

Default	Allowed values	Description
false	true	Use an Approved, Preferred, or Unapproved plan from the <code>apg_plan_mgmt.dba_plans</code> . If none of those meet all evaluation criterion for the optimizer, it can then use its own generated minimum-cost plan. For more information, see <a href="#">How the optimizer chooses which plan to run (p. 1301)</a> .
	false	Use the minimum cost plan generated by the optimizer.

You can evaluate response times of different captured plans and change plan status, as needed. For more information, see [Maintaining Aurora PostgreSQL execution plans \(p. 1304\)](#).

## Function reference for Aurora PostgreSQL query plan management

The `apg_plan_mgmt` extension provides the following functions.

### Functions

- [apg\\_plan\\_mgmt.delete\\_plan \(p. 1311\)](#)
- [apg\\_plan\\_mgmt.evolve\\_plan\\_baselines \(p. 1312\)](#)
- [apg\\_plan\\_mgmt.get\\_explain\\_plan \(p. 1313\)](#)
- [apg\\_plan\\_mgmt.plan\\_last\\_used \(p. 1314\)](#)
- [apg\\_plan\\_mgmt.reload \(p. 1314\)](#)
- [apg\\_plan\\_mgmt.set\\_plan\\_enabled \(p. 1315\)](#)
- [apg\\_plan\\_mgmt.set\\_plan\\_status \(p. 1315\)](#)
- [apg\\_plan\\_mgmt.update\\_plans\\_last\\_used \(p. 1316\)](#)
- [apg\\_plan\\_mgmt.validate\\_plans \(p. 1317\)](#)

## apg\_plan\_mgmt.delete\_plan

Delete a managed plan.

### Syntax

```
apg_plan_mgmt.delete_plan(  
    sql_hash,  
    plan_hash  
)
```

#### Return value

Returns 0 if the delete was successful or -1 if the delete failed.

#### Parameters

Parameter	Description
sql_hash	The <code>sql_hash</code> ID of the plan's managed SQL statement.
plan_hash	The managed plan's <code>plan_hash</code> ID.

## apg\_plan\_mgmt.evolve\_plan\_baseline

Verifies whether an already approved plan is faster or whether a plan identified by the query optimizer as a minimum cost plan is faster.

#### Syntax

```
apg_plan_mgmt.evolve_plan_baseline(
    sql_hash,
    plan_hash,
    min_speedup_factor,
    action
)
```

#### Return value

The number of plans that were not faster than the best approved plan.

#### Parameters

Parameter	Description
sql_hash	The <code>sql_hash</code> ID of the plan's managed SQL statement.
plan_hash	The managed plan's <code>plan_hash</code> ID. Use NULL to mean all plans that have the same <code>sql_hash</code> ID value.
min_speedup_factor	The <i>minimum speedup factor</i> can be the number of times faster that a plan must be than the best of the already approved plans to approve it. Alternatively, this factor can be the number of times slower that a plan must be to reject or disable it.  This is a positive float value.
action	The action the function is to perform. Valid values include the following. Case does not matter. <ul style="list-style-type: none"><li>• 'disable' – Disable each matching plan that does not meet the minimum speedup factor.</li><li>• 'approve' – Enable each matching plan that meets the minimum speedup factor and set its status to <code>approved</code>.</li><li>• 'reject' – For each matching plan that does not meet the minimum speedup factor, set its status to <code>rejected</code>.</li></ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>• NULL – The function simply returns the number of plans that have no performance benefit because they do not meet the minimum speedup factor.</li> </ul>

### Usage notes

Set specified plans to approved, rejected, or disabled based on whether the planning plus execution time is faster than the best approved plan by a factor that you can set. The action parameter might be set to 'approve' or 'reject' to automatically approve or reject a plan that meets the performance criteria. Alternatively, it might be set to "" (empty string) to do the performance experiment and produce a report, but take no action.

You can avoid pointlessly rerunning of the `apg_plan_mgmt.evolve_plan_baselines` function for a plan on which it was recently run. To do so, restrict the plans to just the recently created unapproved plans. Alternatively, you can avoid running the `apg_plan_mgmt.evolve_plan_baselines` function on any approved plan that has a recent `last_verified` timestamp.

Conduct a performance experiment to compare the planning plus execution time of each plan relative to the other plans in the baseline. In some cases, there is only one plan for a statement and the plan is approved. In such a case, compare the planning plus execution time of the plan to the planning plus execution time of using no plan.

The incremental benefit (or disadvantage) of each plan is recorded in the `apg_plan_mgmt.dba_plans` view in the `total_time_benefit_ms` column. When this value is positive, there is a measurable performance advantage to including this plan in the baseline.

In addition to collecting the planning and execution time of each candidate plan, the `last_verified` column of the `apg_plan_mgmt.dba_plans` view is updated with the `current_timestamp`. The `last_verified` timestamp might be used to avoid running this function again on a plan that recently had its performance verified.

## apg\_plan\_mgmt.get\_explain\_plan

Generates the text of an `EXPLAIN` statement for the specified SQL statement.

### Syntax

```
apg_plan_mgmt.get_explain_plan(
    sql_hash,
    plan_hash,
    [explainOptionList]
)
```

### Return value

Returns runtime statistics for the specified SQL statements. Use without `explainOptionList` to return a simple `EXPLAIN` plan.

### Parameters

Parameter	Description
<code>sql_hash</code>	The <code>sql_hash</code> ID of the plan's managed SQL statement.

Parameter	Description
plan_hash	The managed plan's plan_hash ID.
explainOptionList	A comma-separated list of explain options. Valid values include 'analyze', 'verbose', 'buffers', 'hashes', and 'format json'. If the explainOptionList is NULL or an empty string (""), this function generates an EXPLAIN statement, without any statistics.

### Usage notes

For the explainOptionList, you can use any of the same options that you would use with an EXPLAIN statement. The Aurora PostgreSQL optimizer concatenates the list of options that you provide to the EXPLAIN statement.

## apg\_plan\_mgmt.plan\_last\_used

Returns the last\_used date of the specified plan from shared memory.

#### Note

The value in shared memory is always current on the primary DB instance in the DB cluster. The value is only periodically flushed to the last\_used column of the apg\_plan\_mgmt.dba\_plans view.

#### Syntax

```
apg_plan_mgmt.plan_last_used(
    sql_hash,
    plan_hash
)
```

#### Return value

Returns the last\_used date.

#### Parameters

Parameter	Description
sql_hash	The sql_hash ID of the plan's managed SQL statement.
plan_hash	The managed plan's plan_hash ID.

## apg\_plan\_mgmt.reload

Reload plans into shared memory from the apg\_plan\_mgmt.dba\_plans view.

#### Syntax

```
apg_plan_mgmt.reload()
```

#### Return value

None.

#### Parameters

None.

#### Usage notes

Call `reload` for the following situations:

- Use it to refresh the shared memory of a read-only replica immediately, rather than wait for new plans to propagate to the replica.
- Use it after importing managed plans.

## apg\_plan\_mgmt.set\_plan\_enabled

Enable or disable a managed plan.

#### Syntax

```
apg_plan_mgmt.set_plan_enabled(  
    sql_hash,  
    plan_hash,  
    [true | false]  
)
```

#### Return value

Returns 0 if the setting was successful or -1 if the setting failed.

#### Parameters

Parameter	Description
<code>sql_hash</code>	The <code>sql_hash</code> ID of the plan's managed SQL statement.
<code>plan_hash</code>	The managed plan's <code>plan_hash</code> ID.
<code>enabled</code>	Boolean value of true or false: <ul style="list-style-type: none"><li>• A value of <code>true</code> enables the plan.</li><li>• A value of <code>false</code> disables the plan.</li></ul>

## apg\_plan\_mgmt.set\_plan\_status

Set a managed plan's status to Approved, Unapproved, Rejected, or Preferred.

#### Syntax

```
apg_plan_mgmt.set_plan_status(  
    sql_hash,
```

```
    plan_hash,  
    status  
)
```

#### Return value

Returns 0 if the setting was successful or -1 if the setting failed.

#### Parameters

Parameter	Description
sql_hash	The sql_hash ID of the plan's managed SQL statement.
plan_hash	The managed plan's plan_hash ID.
status	A string with one of the following values: <ul style="list-style-type: none"><li>• 'Approved'</li><li>• 'Unapproved'</li><li>• 'Rejected'</li><li>• 'Preferred'</li></ul> The case you use does not matter, however the status value is set to initial uppercase in the apg_plan_mgmt.dba_plans view. For more information about these values, see status in <a href="#">Reference for the apg_plan_mgmt.dba_plans view (p. 1297)</a> .

## apg\_plan\_mgmt.update\_plans\_last\_used

Immediately updates the plans table with the last\_used date stored in shared memory.

#### Syntax

```
apg_plan_mgmt.update_plans_last_used()
```

#### Return value

None.

#### Parameters

None.

#### Usage notes

Call update\_plans\_last\_used to make sure queries against the dba\_plans.last\_used column use the most current information. If the last\_used date isn't updated immediately, a background process updates the plans table with the last\_used date once every hour (by default).

For example, if a statement with a certain sql\_hash begins to run slowly, you can determine which plans for that statement were executed since the performance regression began. To do that, first flush the data in shared memory to disk so that the last\_used dates are current, and then query for all plans of the sql\_hash of the statement with the performance regression. In the query, make sure the

`last_used` date is greater than or equal to the date on which the performance regression began. The query identifies the plan or set of plans that might be responsible for the performance regression. You can use `apg_plan_mgmt.get_explain_plan` with `explainOptionList` set to `verbose`, `hashes`. You can also use `apg_plan_mgmt.evolve_plan_baselines` to analyze the plan and any alternative plans that might perform better.

The `update_plans_last_used` function has an effect only on the primary DB instance of the DB cluster.

## apg\_plan\_mgmt.validate\_plans

Validate that the optimizer can still recreate plans. The optimizer validates `Approved`, `Unapproved`, and `Preferred` plans, whether the plan is enabled or disabled. `Rejected` plans are not validated. Optionally, you can use the `apg_plan_mgmt.validate_plans` function to delete or disable invalid plans.

### Syntax

```
apg_plan_mgmt.validate_plans(  
    sql_hash,  
    plan_hash,  
    action)  
  
apg_plan_mgmt.validate_plans(  
    action)
```

### Return value

The number of invalid plans.

### Parameters

Parameter	Description
<code>sql_hash</code>	The <code>sql_hash</code> ID of the plan's managed SQL statement.
<code>plan_hash</code>	The managed plan's <code>plan_hash</code> ID. Use <code>NULL</code> to mean all plans for the same <code>sql_hash</code> ID value.
<code>action</code>	<p>The action the function is to perform for invalid plans. Valid string values include the following. Case does not matter.</p> <ul style="list-style-type: none"><li>• <code>'disable'</code> – Each invalid plan is disabled.</li><li>• <code>'delete'</code> – Each invalid plan is deleted.</li><li>• <code>'update_plan_hash'</code> – Updates the <code>plan_hash</code> ID for plans that can't be reproduced exactly. It also allows you to fix a plan by rewriting the SQL. You can then register the good plan as an <code>Approved</code> plan for the original SQL.</li><li>• <code>NULL</code> – The function simply returns the number of invalid plans. No other action is performed.</li><li>• <code>" "</code> – An empty string produces a message indicating the number of both valid and invalid plans.</li></ul> <p>Any other value is treated like the empty string.</p>

### Usage notes

Use the form `validate_plans(action)` to validate all the managed plans for all the managed statements in the entire `apg_plan_mgmt.dba_plans` view.

Use the form `validate_plans(sql_hash, plan_hash, action)` to validate a managed plan specified with `plan_hash`, for a managed statement specified with `sql_hash`.

Use the form `validate_plans(sql_hash, NULL, action)` to validate all the managed plans for the managed statement specified with `sql_hash`.

## Working with extensions and foreign data wrappers

To add some types of functionality to your Aurora PostgreSQL-Compatible Edition DB cluster, you can install and use various PostgreSQL extensions. For example, if your use case calls for intensive data entry across very large tables, you can install the `pg_partman` extension to partition your data and thus spread the workload. An extension that provides access to external data is generally known as a *foreign data wrapper* (FDW). As one example, the `oracle_fdw` extension allows your Aurora PostgreSQL DB cluster to work with Oracle databases.

Following, you can find information about setting up and using some of the extensions and FDWs available for Aurora PostgreSQL. For listings of the extensions and FDWs that you can use with currently available Aurora PostgreSQL versions, see [Extension versions for Aurora PostgreSQL-Compatible Edition](#) in the *Release Notes for Aurora PostgreSQL*.

- Managing large objects with the `lo` module ([p. 1318](#))
- Managing spatial data with the PostGIS extension ([p. 1320](#))
- Scheduling maintenance with the PostgreSQL `pg_cron` extension ([p. 1327](#))
- Managing PostgreSQL partitions with the `pg_partman` extension ([p. 1333](#))
- Working with Oracle databases by using the `oracle_fdw` extension ([p. 1337](#))
- Working with SQL Server databases by using the `tds_fdw` extension ([p. 1340](#))

## Managing large objects with the `lo` module

The `lo` module (extension) is for database users and developers working with PostgreSQL databases through JDBC or ODBC drivers. Both JDBC and ODBC expect the database to handle deletion of large objects when references to them change. However, PostgreSQL doesn't work that way. PostgreSQL doesn't assume that an object should be deleted when its reference changes. The result is that objects remain on disk, unreferenced. The `lo` extension includes a function that you use to trigger on reference changes to delete objects if needed.

### Tip

To determine if your database can benefit from the `lo` extension, use the `vacuumlo` utility to check for orphaned large objects. To get counts of orphaned large objects without taking any action, run the utility with the `-n` option (no-op). To learn how, see [vacuumlo utility](#) following.

The `lo` module is available for Aurora PostgreSQL 13.7, 12.11, 11.16, 10.21 and higher minor versions.

To install the module (extension), you need `rds_superuser` privileges. Installing the `lo` extension adds the following to your database:

- `lo` – This is a large object (`lo`) data type that you can use for binary large objects (BLOBs) and other large objects. The `lo` data type is a domain of the `oid` data type. In other words, it's an object

identifier with optional constraints. For more information, see [Object identifiers](#) in the PostgreSQL documentation. In simple terms, you can use the `lo` data type to distinguish your database columns that hold large object references from other object identifiers (OIDs).

- `lo_manage` – This is a function that you can use in triggers on table columns that contain large object references. Whenever you delete or modify a value that references a large object, the trigger unlinks the object (`lo_unlink`) from its reference. Use the trigger on a column only if the column is the sole database reference to the large object.

For more information about the large objects module, see [lo](#) in the PostgreSQL documentation.

## Installing the lo extension

Before installing the `lo` extension, make sure that you have `rds_superuser` privileges.

### To install the `lo` extension

1. Use `psql` to connect to the primary DB instance of your Aurora PostgreSQL DB cluster.

```
psql --host=your-cluster-instance-1.666666666666.aws-region.rds.amazonaws.com --  
port=5432 --username=postgres --password
```

When prompted, enter your password. The `psql` client connects and displays the default administrative connection database, `postgres=>`, as the prompt.

2. Install the extension as follows.

```
postgres=> CREATE EXTENSION lo;  
CREATE EXTENSION
```

You can now use the `lo` data type to define columns in your tables. For example, you can create a table (`images`) that contains raster image data. You can use the `lo` data type for a column `raster`, as shown in the following example, which creates a table.

```
postgres=> CREATE TABLE images (image_name text, raster lo);
```

## Using the `lo_manage` trigger function to delete objects

You can use the `lo_manage` function in a trigger on a `lo` or other large object columns to clean up (and prevent orphaned objects) when the `lo` is updated or deleted.

### To set up triggers on columns that reference large objects

- Do one of the following:
  - Create a BEFORE UPDATE OR DELETE trigger on each column to contain unique references to large objects, using the column name for the argument.

```
postgres=> CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON images  
FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

- Apply a trigger only when the column is being updated.

```
postgres=> CREATE TRIGGER t_raster BEFORE UPDATE OF images  
FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

The `lo_manage` trigger function works only in the context of inserting or deleting column data, depending on how you define the trigger. It has no effect when you perform a `DROP` or `TRUNCATE` operation on a database. That means that you should delete object columns from any tables before dropping, to prevent creating orphaned objects.

For example, suppose that you want to drop the database containing the `images` table. You delete the column as follows.

```
postgres=> DELETE FROM images COLUMN raster
```

Assuming that the `lo_manage` function is defined on that column to handle deletes, you can now safely drop the table.

## Using the `vacuumlo` utility

The `vacuumlo` utility identifies and can remove orphaned large objects from databases. This utility has been available since PostgreSQL 9.1.24. If your database users routinely work with large objects, we recommend that you run `vacuumlo` occasionally to clean up orphaned large objects.

Before installing the `lo` extension, you can use `vacuumlo` to assess whether your Aurora PostgreSQL DB cluster can benefit. To do so, run `vacuumlo` with the `-n` option (no-op) to show what would be removed, as shown in the following:

```
$ vacuumlo -v -n -h your-cluster-instance-1.666666666666.aws-region.rds.amazonaws.com -p
5433 -U postgres docs-lab-spatial-db
Password:*****
Connected to database "docs-lab-spatial-db"
Test run: no large objects will be removed!
Would remove 0 large objects from database "docs-lab-spatial-db".
```

As the output shows, orphaned large objects aren't a problem for this particular database.

For more information about this utility, see [vacuumlo](#) in the PostgreSQL documentation.

## Managing spatial data with the PostGIS extension

PostGIS is an extension to PostgreSQL for storing and managing spatial information. To learn more about PostGIS, see [PostGIS.net](#).

Starting with version 10.5, PostgreSQL supports the libprotobuf 1.3.0 library used by PostGIS for working with map box vector tile data.

Setting up the PostGIS extension requires `rds_superuser` privileges. We recommend that you create a user (role) to manage the PostGIS extension and your spatial data. The PostGIS extension and its related components add thousands of functions to PostgreSQL. Consider creating the PostGIS extension in its own schema if that makes sense for your use case. The following example shows how to install the extension in its own database, but this isn't required.

### Topics

- [Step 1: Create a user \(role\) to manage the PostGIS extension \(p. 1321\)](#)
- [Step 2: Load the PostGIS extensions \(p. 1321\)](#)
- [Step 3: Transfer ownership of the extensions \(p. 1322\)](#)
- [Step 4: Transfer ownership of the PostGIS objects \(p. 1322\)](#)
- [Step 5: Test the extensions \(p. 1323\)](#)
- [Step 6: Upgrade the PostGIS extension \(p. 1323\)](#)

- [PostGIS extension versions \(p. 1324\)](#)
- [Upgrading PostGIS 2 to PostGIS 3 \(p. 1324\)](#)

## Step 1: Create a user (role) to manage the PostGIS extension

First, connect to your RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name when you set up your instance, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

Create a separate role (user) to administer the PostGIS extension.

```
postgres=> CREATE ROLE gis_admin LOGIN PASSWORD 'change_me';
CREATE ROLE
```

Grant this role `rds_superuser` privileges, to allow the role to install the extension.

```
postgres=> GRANT rds_superuser TO gis_admin;
GRANT
```

Create a database to use for your PostGIS artifacts. This step is optional. Or you can create a schema in your user database for the PostGIS extensions, but this also isn't required.

```
postgres=> CREATE DATABASE lab_gis;
CREATE DATABASE
```

Give the `gis_admin` all privileges on the `lab_gis` database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_gis TO gis_admin;
GRANT
```

Exit the session and reconnect to your RDS for PostgreSQL DB instance as `gis_admin`.

```
postgres=> --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=gis_admin --password --dbname=lab_gis
Password for user gis_admin:...
lab_gis=>
```

Continue setting up the extension as detailed in the next steps.

## Step 2: Load the PostGIS extensions

The PostGIS extension includes several related extensions that work together to provide geospatial functionality. Depending on your use case, you might not need all the extensions created in this step.

Use `CREATE EXTENSION` statements to load the PostGIS extensions.

```
CREATE EXTENSION postgis;
CREATE EXTENSION
CREATE EXTENSION postgis_raster;
CREATE EXTENSION
CREATE EXTENSION postgis_tiger_geocoder;
```

```
CREATE EXTENSION
CREATE EXTENSION postgis_topology;
CREATE EXTENSION
CREATE EXTENSION fuzzystrmatch;
CREATE EXTENSION
CREATE EXTENSION address_standardizer_data_us;
CREATE EXTENSION
```

You can verify the results by running the SQL query shown in the following example, which lists the extensions and their owners.

```
SELECT n.nspname AS "Name",
       pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
  FROM pg_catalog.pg_namespace n
 WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
 ORDER BY 1;
List of schemas
   Name      |    Owner
-----+-----
 public    | postgres
 tiger     | rdsadmin
 tiger_data | rdsadmin
 topology   | rdsadmin
(4 rows)
```

## Step 3: Transfer ownership of the extensions

Use the ALTER SCHEMA statements to transfer ownership of the schemas to the gis\_admin role.

```
ALTER SCHEMA tiger OWNER TO gis_admin;
ALTER SCHEMA
ALTER SCHEMA tiger_data OWNER TO gis_admin;
ALTER SCHEMA
ALTER SCHEMA topology OWNER TO gis_admin;
ALTER SCHEMA
```

You can confirm the ownership change by running the following SQL query. Or you can use the \dn metacommand from the psql command line.

```
SELECT n.nspname AS "Name",
       pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
  FROM pg_catalog.pg_namespace n
 WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
 ORDER BY 1;
List of schemas
   Name      |    Owner
-----+-----
 public    | postgres
 tiger     | gis_admin
 tiger_data | gis_admin
 topology   | gis_admin
(4 rows)
```

## Step 4: Transfer ownership of the PostGIS objects

Use the following function to transfer ownership of the PostGIS objects to the gis\_admin role. Run the following statement from the psql prompt to create the function.

```
CREATE FUNCTION exec(text) returns text language plpgsql volatile AS $f$ BEGIN EXECUTE $1;
  RETURN $1; END; $f$;
CREATE FUNCTION
```

Next, run the following query to run the `exec` function that in turn runs the statements and alters the permissions.

```
SELECT exec('ALTER TABLE ' || quote_ident(s.nspname) || '.' || quote_ident(s.relname) || '
OWNER TO gis_admin;');
FROM (
  SELECT nspname, relname
  FROM pg_class c JOIN pg_namespace n ON (c.relnamespace = n.oid)
  WHERE nspname in ('tiger','topology') AND
    relkind IN ('r','S','v') ORDER BY relkind = 'S')
s;
```

## Step 5: Test the extensions

To avoid needing to specify the schema name, add the `tiger` schema to your search path using the following command.

```
SET search_path=public,tiger;
SET
```

Test the `tiger` schema by using the following `SELECT` statement.

```
SELECT address, streetname, streettypeabbrev, zip
  FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;
address | streetname | streettypeabbrev | zip
-----+-----+-----+-----
      1 | Devonshire | Pl             | 02109
(1 row)
```

To learn more about this extension, see [Tiger Geocoder](#) in the PostGIS documentation.

Test access to the `topology` schema by using the following `SELECT` statement. This calls the `createtopology` function to register a new topology object (`my_new_topo`) with the specified spatial reference identifier (26986) and default tolerance (0.5). To learn more, see [CreateTopology](#) in the PostGIS documentation.

```
SELECT topology.createtopology('my_new_topo',26986,0.5);
createtopology
-----
      1
(1 row)
```

## Step 6: Upgrade the PostGIS extension

Each new release of PostgreSQL supports one or more versions of the PostGIS extension compatible with that release. Upgrading the PostgreSQL engine to a new version doesn't automatically upgrade the PostGIS extension. Before upgrading the PostgreSQL engine, you typically upgrade PostGIS to the newest available version for the current PostgreSQL version. For details, see [PostGIS extension versions \(p. 1324\)](#).

After the PostgreSQL engine upgrade, you then upgrade the PostGIS extension again, to the version supported for the newly upgraded PostgreSQL engine version. For more information about

upgrading the PostgreSQL engine, see [Before upgrading your production DB cluster to a new major version \(p. 1419\)](#).

You can check for available PostGIS extension version updates on your Aurora PostgreSQL DB cluster at any time. To do so, run the following command. This function is available with PostGIS 2.5.0 and higher versions.

```
SELECT postGIS_extensions_upgrade();
```

If your application doesn't support the latest PostGIS version, you can install an older version of PostGIS that's available in your major version as follows.

```
CREATE EXTENSION postgis VERSION "2.5.5";
```

If you want to upgrade to a specific PostGIS version from an older version, you can also use the following command.

```
ALTER EXTENSION postgis UPDATE TO "2.5.5";
```

Depending on the version that you're upgrading from, you might need to use this function again. The result of the first run of the function determines if an additional upgrade function is needed. For example, this is the case for upgrading from PostGIS 2 to PostGIS 3. For more information, see [Upgrading PostGIS 2 to PostGIS 3 \(p. 1324\)](#).

If you upgraded this extension to prepare for a major version upgrade of the PostgreSQL engine, you can continue with other preliminary tasks. For more information, see [Before upgrading your production DB cluster to a new major version \(p. 1419\)](#).

## PostGIS extension versions

We recommend that you install the versions of all extensions such as PostGIS as listed in [Extension versions for Aurora PostgreSQL-Compatible Edition](#) in the *Release Notes for Aurora PostgreSQL*. To get a list of versions that are available in your release, use the following command.

```
SELECT * FROM pg_available_extension_versions WHERE name='postgis';
```

You can find version information in the following sections in the *Release Notes for Aurora PostgreSQL*:

- [Extension versions for Aurora PostgreSQL 14](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 13](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 12](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 11](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 10](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 9.6](#)

## Upgrading PostGIS 2 to PostGIS 3

Starting with version 3.0, the PostGIS raster functionality is now a separate extension, `postgis_raster`. This extension has its own installation and upgrade path. This removes dozens of functions, data types, and other artifacts required for raster image processing from the core `postgis`

extension. That means that if your use case doesn't require raster processing, you don't need to install the `postgis_raster` extension.

In the following upgrade example, the first upgrade command extracts raster functionality into the `postgis_raster` extension. A second upgrade command is then required to upgrade `postres_raster` to the new version.

### To upgrade from PostGIS 2 to PostGIS 3

1. Identify the default version of PostGIS that's available to the PostgreSQL version on your Aurora PostgreSQL DB cluster. To do so, run the following query.

```
SELECT * FROM pg_available_extensions
  WHERE default_version > installed_version;
    name | default_version | installed_version | comment
-----+-----+-----+
+-----+
 postgis | 3.1.4           | 2.3.7          | PostGIS geometry and geography spatial
 types and functions
(1 row)
```

2. Identify the versions of PostGIS installed in each database on the writer instance of your Aurora PostgreSQL DB cluster. In other words, query each user database as follows.

```
SELECT
  e.extname AS "Name",
  e.extversion AS "Version",
  n.nspname AS "Schema",
  c.description AS "Description"
FROM
  pg_catalog.pg_extension e
  LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
  LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
    AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
  e.extname LIKE '%postgis%'
ORDER BY
  1;
  Name | Version | Schema | Description
-----+-----+-----+
+-----+
 postgis | 2.3.7   | public  | PostGIS geometry, geography, and raster spatial types and
 functions
(1 row)
```

This mismatch between the default version (PostGIS 3.1.4) and the installed version (PostGIS 2.3.7) means that you need to upgrade the PostGIS extension.

```
ALTER EXTENSION postgis UPDATE;
ALTER EXTENSION
WARNING: unpackaging raster
WARNING: PostGIS Raster functionality has been unpackaged
```

3. Run the following query to verify that the raster functionality is now in its own package.

```
SELECT
  probin,
  count(*)
FROM
  pg_proc
WHERE
```

```

    probin LIKE '%postgis%'
GROUP BY
    probin;
    probin      | count
-----
$libdir/rtpostgis-2.3   | 107
$libdir/postgis-3       | 487
(2 rows)

```

The output shows that there's still a difference between versions. The PostGIS functions are version 3 (postgis-3), while the raster functions (rtpostgis) are version 2 (rtpostgis-2.3). To complete the upgrade, you run the upgrade command again, as follows.

```
postgres=> SELECT postgis_extensions_upgrade();
```

You can safely ignore the warning messages. Run the following query again to verify that the upgrade is complete. The upgrade is complete when PostGIS and all related extensions aren't marked as needing upgrade.

```
SELECT postgis_full_version();
```

4. Use the following query to see the completed upgrade process and the separately packaged extensions, and verify that their versions match.

```

SELECT
    e.extname AS "Name",
    e.extversion AS "Version",
    n.nspname AS "Schema",
    c.description AS "Description"
FROM
    pg_catalog.pg_extension e
    LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
    LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
        AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
    e.extname LIKE '%postgis%'
ORDER BY
    1;
    Name      | Version | Schema | Description
-----
+-----+
postgis      | 3.1.5   | public  | PostGIS geometry, geography, and raster spatial
types and functions
postgis_raster | 3.1.5   | public  | PostGIS raster types and functions
(2 rows)

```

The output shows that the PostGIS 2 extension was upgraded to PostGIS 3, and both `postgis` and the now separate `postgis_raster` extension are version 3.1.5.

After this upgrade completes, if you don't plan to use the raster functionality, you can drop the extension as follows.

```
DROP EXTENSION postgis_raster;
```

# Scheduling maintenance with the PostgreSQL pg\_cron extension

You can use the PostgreSQL pg\_cron extension to schedule maintenance commands within a PostgreSQL database. For more information about the extension, see [What is pg\\_cron?](#) in the pg\_cron documentation.

The pg\_cron extension is supported on Aurora PostgreSQL engine versions 12.6 and higher version

To learn more about using pg\_cron, see [Schedule jobs with pg\\_cron on your RDS for PostgreSQL or your Aurora PostgreSQL-Compatible Edition databases](#)

## Topics

- [Setting up the pg\\_cron extension \(p. 1327\)](#)
- [Granting permissions to use pg\\_cron \(p. 1327\)](#)
- [Scheduling pg\\_cron jobs \(p. 1328\)](#)
- [pg\\_cron reference \(p. 1330\)](#)

## Setting up the pg\_cron extension

Set up the pg\_cron extension as follows:

1. Modify the custom parameter group associated with your PostgreSQL DB instance by adding pg\_cron to the shared\_preload\_libraries parameter value.

Restart the PostgreSQL DB instance to have changes to the parameter group take effect. To learn more about working with parameter groups, see [Amazon Aurora PostgreSQL parameters \(p. 1369\)](#).

2. After the PostgreSQL DB instance has restarted, run the following command using an account that has rds\_superuser permissions. For example, if you used the default settings when you created your Aurora PostgreSQL DB cluster, connect as user postgres and create the extension.

```
CREATE EXTENSION pg_cron;
```

The pg\_cron scheduler is set in the default PostgreSQL database named postgres. The pg\_cron objects are created in this postgres database and all scheduling actions run in this database.

3. You can use the default settings, or you can schedule jobs to run in other databases within your PostgreSQL DB instance. To schedule jobs for other databases within your PostgreSQL DB instance, see the example in [Scheduling a cron job for a database other than postgres \(p. 1329\)](#).

## Granting permissions to use pg\_cron

Installing the pg\_cron extension requires the rds\_superuser privileges. However, permissions to use the pg\_cron can be granted (by a member of the rds\_superuser group/role) to other database users, so that they can schedule their own jobs. We recommend that you grant permissions to the cron schema only as needed if it improves operations in your production environment.

To grant a database user permission in the cron schema, run the following command:

```
postgres=> GRANT USAGE ON SCHEMA cron TO db-user;
```

This gives `db-user` permission to access the `cron` schema to schedule cron jobs for the objects that they have permissions to access. If the database user doesn't have permissions, the job fails after posting the error message to the `postgresql.log` file, as shown in the following:

```
2020-12-08 16:41:00 UTC::@[30647]:ERROR: permission denied for table table-name
2020-12-08 16:41:00 UTC::@[27071]:LOG: background worker "pg_cron" (PID 30647) exited with
exit code 1
```

IN other words, make sure that database users that are granted permissions on the `cron` schema also have permissions on the objects (tables, schemas, and so on) that they plan to schedule.

The details of the cron job and its success or failure are also captured in the `cron.job_run_details` table. For more information, see [The pg\\_cron tables \(p. 1332\)](#).

## Scheduling pg\_cron jobs

The following sections show how you can schedule various management tasks using `pg_cron` jobs.

### Note

When you create `pg_cron` jobs, check that the `max_worker_processes` setting is larger than the number of `cron.max_running_jobs`. A `pg_cron` job fails if it runs out of background worker processes. The default number of `pg_cron` jobs is 5. For more information, see [The pg\\_cron parameters \(p. 1330\)](#).

### Topics

- [Vacuuming a table \(p. 1328\)](#)
- [Purging the pg\\_cron history table \(p. 1329\)](#)
- [Disabling logging of pg\\_cron history \(p. 1329\)](#)
- [Scheduling a cron job for a database other than postgres \(p. 1329\)](#)

## Vacuuming a table

Autovacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

Following is an example of using the `cron.schedule` function to set up a job to use `VACUUM FREEZE` on a specific table every day at 22:00 (GMT).

```
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
schedule
-----
1
(1 row)
```

After the preceding example runs, you can check the history in the `cron.job_run_details` table as follows.

```
postgres=> SELECT * FROM cron.job_run_details;
jobid | runid | job_pid | database | username | command | status
      |       |         |          |          |          | end_time
-----+-----+-----+-----+-----+-----+-----+
      |
      +-----+
      1   | 1    | 3395   | postgres | adminuser| vacuum freeze pgbench_accounts | succeeded
      | VACUUM |          | 2020-12-04 21:10:00.050386+00 | 2020-12-04 21:10:00.072028+00
(1 row)
```

Following is an querying the cron.job\_run\_details table to see failed jobs.

```
postgres=> SELECT * FROM cron.job_run_details WHERE status = 'failed';
jobid | runid | job_pid | database | username | command
      |       |          |          |          |           | status
      |       |          |          |          |           | start_time
      |       |          |          |          |           | end_time
-----+-----+-----+-----+-----+-----+-----+
+-----+
+-----+
5    | 4    | 30339   | postgres | adminuser| vacuum freeze pgbench_account | failed
| ERROR: relation "pgbench_account" does not exist | 2020-12-04 21:48:00.015145+00 |
2020-12-04 21:48:00.029567+00
(1 row)
```

For more information, see [The pg\\_cron tables \(p. 1332\)](#).

## Purging the pg\_cron history table

The cron.job\_run\_details table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the [cron.schedule \(p. 1331\)](#) function to schedule a job that runs every day at midnight to purge the cron.job\_run\_details table. The job keeps only the last seven days. Use your rds\_superuser account to schedule the job such as the following.

```
SELECT cron.schedule('0 0 * * *', $$DELETE
                     FROM cron.job_run_details
                     WHERE end_time < now() - interval '7 days'$$);
```

For more information, see [The pg\\_cron tables \(p. 1332\)](#).

## Disabling logging of pg\_cron history

To completely disable writing anything to the cron.job\_run\_details table, modify the parameter group associated with the PostgreSQL DB instance and set the cron.log\_run parameter to off. If you do this, the pg\_cron extension no longer writes to the table and produces errors only in the postgresql.log file. For more information, see [Modifying parameters in a DB parameter group \(p. 231\)](#).

Use the following command to check the value of the cron.log\_run parameter.

```
postgres=> SHOW cron.log_run;
```

For more information, see [The pg\\_cron parameters \(p. 1330\)](#).

## Scheduling a cron job for a database other than postgres

The metadata for pg\_cron is all held in the PostgreSQL default database named `postgres`. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

1. In the cron database, schedule the job as you normally do using the [cron.schedule \(p. 1331\)](#).

```
postgres=> SELECT cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum freeze
                     test_table');
```

2. As a user with the `rds_superuser` role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

```
postgres=> UPDATE cron.job SET database = 'database1' WHERE jobid = 106;
```

3. Verify by querying the cron.job table.

```
postgres=> SELECT * FROM cron.job;
   jobid | schedule      | command                                     | nodename | nodeport | database |
   username | active | jobname
-----+-----+-----+-----+-----+-----+
106    | 29 03 * * * | vacuum freeze test_table           | localhost | 8192     | database1|
adminuser | t      | database1 manual vacuum
1       | 59 23 * * * | vacuum freeze pgbench_accounts | localhost | 8192     | postgres  |
adminuser | t      | manual vacuum
(2 rows)
```

#### Note

In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (`postgres`) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

## pg\_cron reference

You can use the following parameters, functions, and tables with the pg\_cron extension. For more information, see [What is pg\\_cron?](#) in the pg\_cron documentation.

### Topics

- [The pg\\_cron parameters \(p. 1330\)](#)
- [The cron.schedule\(\) function \(p. 1331\)](#)
- [The cron.unschedule\(\) function \(p. 1331\)](#)
- [The pg\\_cron tables \(p. 1332\)](#)

## The pg\_cron parameters

Following is a list of parameters that control the pg\_cron extension behavior.

Parameter	Description
<code>cron.database_name</code>	The database in which pg_cron metadata is kept.
<code>cron.host</code>	The hostname to connect to PostgreSQL. You can't modify this value.
<code>cron.log_run</code>	Log every job that runs in the <code>job_run_details</code> table. Values are <code>on</code> or <code>off</code> . For more information, see <a href="#">The pg_cron tables (p. 1332)</a> .
<code>cron.log_statement</code>	Log all cron statements before running them. Values are <code>on</code> or <code>off</code> .
<code>cron.max_running_jobs</code>	The maximum number of jobs that can run concurrently.
<code>cron.use_background_workers</code>	Use background workers instead of client sessions. You can't modify this value.

Use the following SQL command to display these parameters and their values.

```
postgres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%' ORDER BY name;
```

## The cron.schedule() function

This function schedules a cron job. The job is initially scheduled in the default `postgres` database. The function returns a bigint value representing the job identifier. To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in [Scheduling a cron job for a database other than postgres \(p. 1329\)](#).

The function has two syntax formats.

### Syntax

```
cron.schedule (job_name,  
              schedule,  
              command  
);  
  
cron.schedule (schedule,  
              command  
);
```

### Parameters

Parameter	Description
<code>job_name</code>	The name of the cron job.
<code>schedule</code>	Text indicating the schedule for the cron job. The format is the standard cron format.
<code>command</code>	Text of the command to run.

### Examples

```
postgres=> SELECT cron.schedule ('test','0 10 * * *', 'VACUUM pgbench_history');  
schedule  
-----  
      145  
(1 row)  
  
postgres=> SELECT cron.schedule ('0 15 * * *', 'VACUUM pgbench_accounts');  
schedule  
-----  
      146  
(1 row)
```

## The cron.unschedule() function

This function deletes a cron job. You can specify either the `job_name` or the `job_id`. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

## Syntax

```
cron.unschedule (job_id);
cron.unschedule (job_name);
```

## Parameters

Parameter	Description
job_id	A job identifier that was returned from the <code>cron.schedule</code> function when the cron job was scheduled.
job_name	The name of a cron job that was scheduled with the <code>cron.schedule</code> function.

## Examples

```
postgres=> SELECT cron.unschedule(108);
      unschedule
      -----
      t
(1 row)

postgres=> SELECT cron.unschedule('test');
      unschedule
      -----
      t
(1 row)
```

## The pg\_cron tables

The following tables are used to schedule the cron jobs and record how the jobs completed.

Table	Description
<code>cron.job</code>	<p>Contains the metadata about each scheduled job. Most interactions with this table should be done by using the <code>cron.schedule</code> and <code>cron.unschedule</code> functions.</p> <p><b>Important</b> We recommend that you don't give update or insert privileges directly to this table. Doing so would allow the user to update the <code>username</code> column to run as <code>rds-superuser</code>.</p>
<code>cron.job_run_details</code>	<p>Contains historic information about past scheduled jobs that ran. This is useful to investigate the status, return messages, and start and end time from the job that ran.</p> <p><b>Note</b> To prevent this table from growing indefinitely, purge it on a regular basis.</p>

Table	Description
	For an example, see <a href="#">Purging the pg_cron history table (p. 1329)</a> .

## Managing PostgreSQL partitions with the pg\_partman extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.

By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions holds one day's worth of data, and so on. The partition key controls the size of a partition.

When you use an `INSERT` or `UPDATE` SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the `WHERE` clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.

For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.

- New partitions inherit the parent database table properties, including the following:
  - Indexes
  - Primary keys, which must include the partition key column
  - Foreign keys
  - Check constraints
  - References
- Creating indexes for the full table or each specific partition.

You can't alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

### Topics

- [Overview of the PostgreSQL pg\\_partman extension \(p. 1334\)](#)
- [Enabling the pg\\_partman extension \(p. 1334\)](#)
- [Configuring partitions using the create\\_parent function \(p. 1335\)](#)

- Configuring partition maintenance using the `run_maintenance_proc` function (p. 1336)

## Overview of the PostgreSQL pg\_partman extension

You can use the PostgreSQL `pg_partman` extension to automate the creation and maintenance of table partitions. For more general information, see [PG Partition Manager](#) in the `pg_partman` documentation.

**Note**

The `pg_partman` extension is supported on Aurora PostgreSQL versions 12.6 and higher.

Instead of having to manually create each partition, you configure `pg_partman` with the following settings:

- Table to be partitioned
- Partition type
- Partition key
- Partition granularity
- Partition precreation and management options

After you create a PostgreSQL partitioned table, you register it with `pg_partman` by calling the `create_parent` function. Doing this creates the necessary partitions based on the parameters you pass to the function.

The `pg_partman` extension also provides the `run_maintenance_proc` function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

## Enabling the pg\_partman extension

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the `pg_partman` extension separately for each database. To enable the `pg_partman` extension for a specific database, create the partition maintenance schema and then create the `pg_partman` extension as follows.

```
CREATE SCHEMA partman;
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

**Note**

To create the `pg_partman` extension, make sure that you have `rds_superuser` privileges.

If you receive an error such as the following, grant the `rds_superuser` privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"
HINT: Must be superuser to create this extension.
```

To grant `rds_superuser` privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the `pg_partman` extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp. A schema `data_mart`

contains a table named `events` with a column named `created_at`. The following settings are included in the `events` table:

- Primary keys `event_id` and `created_at`, which must have the column used to guide the partition.
- A check constraint `ck_valid_operation` to enforce values for an `operation` table column.
- Two foreign keys, where one (`fk_orga_membership`) points to the external table `organization` and the other (`fk_parent_event_id`) is a self-referenced foreign key.
- Two indexes, where one (`idx_org_id`) is for the foreign key and the other (`idx_event_type`) is for the event type.

The follow DDL statements create these objects, which are automatically included on each partition.

```

CREATE SCHEMA data_mart;
CREATE TABLE data_mart.organization (
    org_id BIGSERIAL,
    org_name TEXT,
    CONSTRAINT pk_organization PRIMARY KEY (org_id)
);

CREATE TABLE data_mart.events(
    event_id      BIGSERIAL,
    operation     CHAR(1),
    value         FLOAT(24),
    parent_event_id BIGINT,
    event_type    VARCHAR(25),
    org_id        BIGSERIAL,
    created_at    timestamp,
    CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at),
    CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'),
    CONSTRAINT fk_orga_membership
        FOREIGN KEY(org_id)
        REFERENCES data_mart.organization (org_id),
    CONSTRAINT fk_parent_event_id
        FOREIGN KEY(parent_event_id, created_at)
        REFERENCES data_mart.events (event_id, created_at)
) PARTITION BY RANGE (created_at);

CREATE INDEX idx_org_id      ON data_mart.events(org_id);
CREATE INDEX idx_event_type ON data_mart.events(event_type);

```

## Configuring partitions using the `create_parent` function

After you enable the `pg_partman` extension, use the `create_parent` function to configure partitions inside the partition maintenance schema. The following example uses the `events` table example created in [Enabling the pg\\_partman extension \(p. 1334\)](#). Call the `create_parent` function as follows.

```

SELECT partman.create_parent(
    p_parent_table => 'data_mart.events',
    p_control => 'created_at',
    p_type => 'native',
    p_interval=> 'daily',
    p_premake => 30);

```

The parameters are as follows:

- `p_parent_table` – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
- `p_control` – The column on which the partitioning is to be based. The data type must be an integer or time-based.

- `p_type` – The type is either 'native' or 'partman'. You typically use the native type for its performance improvements and flexibility. The partman type relies on inheritance.
- `p_interval` – The time interval or integer range for each partition. Example values include daily, hourly, and so on.
- `p_premake` – The number of partitions to create in advance to support new inserts.

For a complete description of the `create_parent` function, see [Creation Functions](#) in the pg\_partman documentation.

## Configuring partition maintenance using the `run_maintenance_proc` function

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the `run_maintenance_proc` function of the pg\_partman extension and the pg\_cron extension, which initiates an internal scheduler. The pg\_cron scheduler automatically executes SQL statements, functions, and procedures defined in your databases.

The following example uses the events table example created in [Enabling the pg\\_partman extension \(p. 1334\)](#) to set partition maintenance operations to run automatically. As a prerequisite, add pg\_cron to the `shared_preload_libraries` parameter in the DB instance's parameter group.

```
CREATE EXTENSION pg_cron;

UPDATE partman.part_config
SET infinite_time_partitions = true,
    retention = '3 months',
    retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);
```

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add pg\_cron to the `shared_preload_libraries` parameter value. This change requires a DB instance restart for it to take effect. For more information, see [Modifying parameters in a DB parameter group \(p. 231\)](#).
2. Run the command `CREATE EXTENSION pg_cron;` using an account that has the `rds_superuser` permissions. Doing this enables the pg\_cron extension. For more information, see [Scheduling maintenance with the PostgreSQL pg\\_cron extension \(p. 1327\)](#).
3. Run the command `UPDATE partman.part_config` to adjust the pg\_partman settings for the `data_mart.events` table.
4. Run the command `SET ...` to configure the `data_mart.events` table, with these clauses:
  - a. `infinite_time_partitions = true`, – Configures the table to be able to automatically create new partitions without any limit.
  - b. `retention = '3 months'`, – Configures the table to have a maximum retention of three months.
  - c. `retention_keep_table=true` – Configures the table so that when the retention period is due, the table isn't deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.
5. Run the command `SELECT cron.schedule ...` to make a pg\_cron function call. This call defines how often the scheduler runs the pg\_partman maintenance procedure, `partman.run_maintenance_proc`. For this example, the procedure runs every hour.

For a complete description of the `run_maintenance_proc` function, see [Maintenance Functions](#) in the pg\_partman documentation.

# Working with the supported foreign data wrappers for Amazon Aurora PostgreSQL

A foreign data wrapper (FDW) is a specific type of extension that provides access to external data. For example, the `oracle_fdw` extension allows your Aurora PostgreSQL DB instance to work with Oracle databases.

Following, you can find information about several supported PostgreSQL foreign data wrappers.

## Topics

- [Working with Oracle databases by using the oracle\\_fdw extension \(p. 1337\)](#)
- [Working with SQL Server databases by using the tds\\_fdw extension \(p. 1340\)](#)

## Working with Oracle databases by using the oracle\_fdw extension

To access an Oracle database from your Aurora PostgreSQL DB cluster you can install and use the `oracle_fdw` extension. This extension is a foreign data wrapper for Oracle databases. To learn more about this extension, see the [oracle\\_fdw](#) documentation.

The `oracle_fdw` extension is supported on Aurora PostgreSQL 12.7 (Amazon Aurora release 4.2) and higher versions.

## Topics

- [Turning on the oracle\\_fdw extension \(p. 1337\)](#)
- [Example: Using a foreign server linked to an Amazon RDS for Oracle database \(p. 1337\)](#)
- [Working with encryption in transit \(p. 1338\)](#)
- [Understanding the pg\\_user\\_mappings view and permissions \(p. 1338\)](#)

### Turning on the oracle\_fdw extension

To use the `oracle_fdw` extension, perform the following procedure.

#### To turn on the oracle\_fdw extension

- Run the following command using an account that has `rds_superuser` permissions.

```
CREATE EXTENSION oracle_fdw;
```

### Example: Using a foreign server linked to an Amazon RDS for Oracle database

The following example shows the use of a foreign server linked to an Amazon RDS for Oracle database.

#### To create a foreign server linked to an RDS for Oracle database

1. Note the following on the RDS for Oracle DB instance:
  - Endpoint
  - Port
  - Database name
2. Create a foreign server.

```
test=> CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw OPTIONS (dbserver
'//endpoint:port/DB_name');
CREATE SERVER
```

3. Grant usage to a user who doesn't have `rds_superuser` privileges, for example `user1`.

```
test=> GRANT USAGE ON FOREIGN SERVER oradb TO user1;
GRANT
```

4. Connect as `user1`, and create a mapping to an Oracle user.

```
test=> CREATE USER MAPPING FOR user1 SERVER oradb OPTIONS (user 'oracleuser', password
'mypassword');
CREATE USER MAPPING
```

5. Create a foreign table linked to an Oracle table.

```
test=> CREATE FOREIGN TABLE mytab (a int) SERVER oradb OPTIONS (table 'MYTABLE');
CREATE FOREIGN TABLE
```

6. Query the foreign table.

```
test=> SELECT * FROM mytab;
a
---
1
(1 row)
```

If the query reports the following error, check your security group and access control list (ACL) to make sure that both instances can communicate.

```
ERROR: connection for foreign table "mytab" cannot be established
DETAIL: ORA-12170: TNS:Connect timeout occurred
```

## Working with encryption in transit

PostgreSQL-to-Oracle encryption in transit is based on a combination of client and server configuration parameters. For an example using Oracle 21c, see [About the Values for Negotiating Encryption and Integrity](#) in the Oracle documentation. The client used for `oracle_fdw` on Amazon RDS is configured with `ACCEPTED`, meaning that the encryption depends on the Oracle database server configuration.

If your database is on RDS for Oracle, see [Oracle native network encryption](#) to configure the encryption.

## Understanding the `pg_user_mappings` view and permissions

The PostgreSQL catalog `pg_user_mapping` stores the mapping from an Aurora PostgreSQL user to the user on a foreign data (remote) server. Access to the catalog is restricted, but you use the `pg_user_mappings` view to see the mappings. In the following, you can find an example that shows how permissions apply with an example Oracle database, but this information applies more generally to any foreign data wrapper.

In the following output, you can find roles and permissions mapped to three different example users. Users `rdssu1` and `rdssu2` are members of the `rds_superuser` role, and `user1` isn't. The example uses the `psql` metacommand `\du` to list existing roles.

```
test=> \du
```

List of roles

Role name	Attributes
Member of	
rdssu1	
{rds_superuser}	
rdssu2	
{rds_superuser}	
user1	{}

All users, including users that have `rds_superuser` privileges, are allowed to view their own user mappings (`umoptions`) in the `pg_user_mappings` table. As shown in the following example, when `rdssu1` tries to obtain all user mappings, an error is raised even though `rdssu1`'s `rds_superuser` privileges:

```
test=> SELECT * FROM pg_user_mapping;
ERROR: permission denied for table pg_user_mapping
```

Following are some examples.

```
test=> SET SESSION AUTHORIZATION rdssu1;
SET
test=> SELECT * FROM pg_user_mappings;
 umid | srvid | srvname | umuser | username | umoptions
-----+-----+-----+-----+-----+
 16414 | 16411 | oradb | 16412 | user1 |
 16423 | 16411 | oradb | 16421 | rdssu1 | {user=oracleuser,password=mypwd}
 16424 | 16411 | oradb | 16422 | rdssu2 |
(3 rows)

test=> SET SESSION AUTHORIZATION rdssu2;
SET
test=> SELECT * FROM pg_user_mappings;
 umid | srvid | srvname | umuser | username | umoptions
-----+-----+-----+-----+-----+
 16414 | 16411 | oradb | 16412 | user1 |
 16423 | 16411 | oradb | 16421 | rdssu1 |
 16424 | 16411 | oradb | 16422 | rdssu2 | {user=oracleuser,password=mypwd}
(3 rows)

test=> SET SESSION AUTHORIZATION user1;
SET
test=> SELECT * FROM pg_user_mappings;
 umid | srvid | srvname | umuser | username | umoptions
-----+-----+-----+-----+-----+
 16414 | 16411 | oradb | 16412 | user1 | {user=oracleuser,password=mypwd}
 16423 | 16411 | oradb | 16421 | rdssu1 |
 16424 | 16411 | oradb | 16422 | rdssu2 |
(3 rows)
```

Because of implementation differences between `information_schema.pg_user_mappings` and `pg_catalog.pg_user_mappings`, a manually created `rds_superuser` requires additional permissions to view passwords in `pg_catalog.pg_user_mappings`.

No additional permissions are required for an `rds_superuser` to view passwords in `information_schema.pg_user_mappings`.

Users who don't have the `rds_superuser` role can view passwords in `pg_user_mappings` only under the following conditions:

- The current user is the user being mapped and owns the server or holds the `USAGE` privilege on it.
- The current user is the server owner and the mapping is for `PUBLIC`.

## Working with SQL Server databases by using the tds\_fdw extension

You can use the PostgreSQL tds\_fdw extension to access databases that support the tabular data stream (TDS) protocol, such as Sybase and Microsoft SQL Server databases. This foreign data wrapper lets you connect from your Aurora PostgreSQL DB cluster to databases that use the TDS protocol, including Amazon RDS for Microsoft SQL Server. For more information, see [tds-fdw/tds\\_fdw](#) documentation on GitHub.

The tds\_fdw extension is supported on Amazon Aurora PostgreSQL version 13.6 and higher releases.

### Setting up your RDS for PostgreSQL DB to use the tds\_fdw extension

In the following procedures, you can find an example of setting up and using the tds\_fdw with an Aurora PostgreSQL DB cluster. Before you can connect to a SQL Server database using tds\_fdw, you need to get the following details for the instance:

- Hostname or endpoint. For an RDS for SQL Server DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for Microsoft SQL Server is 1433.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the SQL Server port, 1433. Both the Aurora PostgreSQL DB cluster and the RDS for SQL Server DB instance need access to port 1433. If access isn't configured correctly, when you try to query the Microsoft SQL Server you see the following error message:

```
ERROR: DB-Library error: DB #: 20009, DB Msg: Unable to connect:  
Adaptive Server is unavailable or does not exist (mssql2019.aws-region.rds.amazonaws.com),  
OS #: 0, OS Msg: Success, Level: 9
```

### To use tds\_fdw to connect to a SQL Server database

1. Connect to your Aurora PostgreSQL DB cluster's primary instance using an account that has the rds\_superuser role:

```
psql --host=your-cluster-name-instance-1.aws-region.rds.amazonaws.com --port=5432 --  
username=test --password
```

2. Install the tds\_fdw extension:

```
test=> CREATE EXTENSION tds_fdw;  
CREATE EXTENSION
```

After the extension is installed on your Aurora PostgreSQL DB cluster , you set up the foreign server.

### To create the foreign server

Perform these tasks on the Aurora PostgreSQL DB cluster using an account that has rds\_superuser privileges.

1. Create a foreign server in the Aurora PostgreSQL DB cluster:

```
test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS (servername  
'mssql2019.aws-region.rds.amazonaws.com', port '1433', database 'tds\_fdw\_testing');
```

```
CREATE SERVER
```

2. Grant permissions to a user who doesn't have `rds_superuser` role privileges, for example, `user1`:

```
test=> GRANT USAGE ON FOREIGN SERVER sqlserverdb TO user1;
```

3. Connect as `user1` and create a mapping to a SQL Server user:

```
test=> CREATE USER MAPPING FOR user1 SERVER sqlserverdb OPTIONS (username 'sqlserveruser', password 'password');  
CREATE USER MAPPING
```

4. Create a foreign table linked to a SQL Server table:

```
test=> CREATE FOREIGN TABLE mytab (a int) SERVER sqlserverdb OPTIONS (table 'MYTABLE');  
CREATE FOREIGN TABLE
```

5. Query the foreign table:

```
test=> SELECT * FROM mytab;  
a  
---  
1  
(1 row)
```

### Using encryption in transit for the connection

The connection from Aurora PostgreSQL to SQL Server uses encryption in transit (TLS/SSL) depending on the SQL Server database configuration. If the SQL Server isn't configured for encryption, the RDS for PostgreSQL client making the request to the SQL Server database falls back to unencrypted.

You can enforce encryption for the connection to RDS for SQL Server DB instances by setting the `rds.force_ssl` parameter. To learn how, see [Forcing connections to your DB instance to use SSL](#). For more information about SSL/TLS configuration for RDS for SQL Server, see [Using SSL with a Microsoft SQL Server DB instance](#).

## Amazon Aurora PostgreSQL reference

### Topics

- [Aurora PostgreSQL collations for EBCDIC and other mainframe migrations \(p. 1341\)](#)

## Aurora PostgreSQL collations for EBCDIC and other mainframe migrations

Migrating mainframe applications to new platforms such as AWS ideally preserves application behavior. To preserve application behavior on a new platform exactly as it was on the mainframe requires that migrated data be collated using the same collation and sorting rules. For example, many Db2 migration solutions shift null values to u0180 (Unicode position 0180), so these collations sort u0180 first. This is

one example of how collations can vary from their mainframe source and why it's necessary to choose a collation that better maps to the original EBCDIC collation.

Aurora PostgreSQL 14.3 and higher versions provide many ICU and EBCDIC collations to support such migration to AWS using the AWS Mainframe Modernization service. To learn more about this service, see [What is AWS Mainframe Modernization?](#)

In the following table, you can find Aurora PostgreSQL–provided collations. These collations follow EBCDIC rules and ensure that mainframe applications function the same on AWS as they did in the mainframe environment. The collation name includes the relevant code page, (cpnnnn), so that you can choose the appropriate collation for your mainframe source. For example, use en-US-cp037-x-icu for to achieve the collation behavior for EBCDIC data that originated from a mainframe application that used code page 037.

EBCDIC collations	AWS Blu Age collations	AWS Micro Focus collations
da-DK-cp1142-x-icu	da-DK-cp1142b-x-icu	da-DK-cp1142m-x-icu

To learn more about AWS Blu Age, see [Tutorial: Managed Runtime for AWS Blu Age in the AWS Mainframe Modernization User Guide](#).

For more information about working with AWS Micro Focus, see [Tutorial: Managed Runtime for Micro Focus in the AWS Mainframe Modernization User Guide](#).

For more information about managing collations in PostgreSQL, see [Collation Support](#) in the PostgreSQL documentation.

# Aurora PostgreSQL functions reference

Following, you can find a list of Aurora PostgreSQL functions that are available for your Aurora DB clusters that run the Aurora PostgreSQL-Compatible Edition DB engine. These Aurora PostgreSQL functions are in addition to the standard PostgreSQL functions. For more information about standard PostgreSQL functions, see [PostgreSQL–Functions and Operators](#).

## Overview

You can use the following functions for Amazon RDS DB instances running Aurora PostgreSQL:

- [aurora\\_db\\_instance\\_identifier \(p. 1343\)](#)
- [aurora\\_ccm\\_status \(p. 1344\)](#)
- [aurora\\_global\\_db\\_instance\\_status \(p. 1346\)](#)
- [aurora\\_global\\_db\\_status \(p. 1348\)](#)
- [aurora\\_list\\_builtin \(p. 1350\)](#)
- [aurora\\_replica\\_status \(p. 1351\)](#)
- [aurora\\_stat\\_backend\\_waits \(p. 1354\)](#)
- [aurora\\_stat\\_dml\\_activity \(p. 1357\)](#)
- [aurora\\_stat\\_get\\_db\\_commit\\_latency \(p. 1359\)](#)
- [aurora\\_stat\\_system\\_waits \(p. 1361\)](#)
- [aurora\\_stat\\_wait\\_event \(p. 1362\)](#)
- [aurora\\_stat\\_wait\\_type \(p. 1364\)](#)
- [aurora\\_version \(p. 1365\)](#)
- [aurora\\_wait\\_report \(p. 1367\)](#)

## aurora\_db\_instance\_identifier

Reports the name of the DB instance name to which you're connected.

### Syntax

```
aurora_db_instance_identifier()
```

### Arguments

None

### Return type

VARCHAR string

### Usage notes

This function displays the name of Aurora PostgreSQL-Compatible Edition cluster's DB instance for your database client or application connection.

This function is available starting with the release of Aurora PostgreSQL versions 13.7, 12.11, 11.16, 10.21 and for all other later versions.

## Examples

The following example shows results of calling the `aurora_db_instance_identifier` function.

```
=> SELECT aurora_db_instance_identifier();aurora_db_instance_identifier
-----
 test-my-instance-name
```

You can join the results of this function with the `aurora_replica_status` function to obtain details about the DB instance for your connection. The [aurora\\_replica\\_status \(p. 1351\)](#) alone doesn't provide show you which DB instance you're using. The following example shows you how.

```
=> SELECT *
   FROM aurora_replica_status() rt,
        aurora_db_instance_identifier() di
  WHERE r.server_id = di;
-[ RECORD 1 ]-----+
server_id           | test-my-instance-name
session_id          | MASTER_SESSION_ID
durable_lsn         | 88492069
highest_lsn_rcvd    |
current_read_lsn    |
cur_replay_latency_in_usec |
active_txns         |
is_current          | t
last_transport_error | 0
last_error_timestamp |
last_update_timestamp | 2022-06-03 11:18:25+00
feedback_xmin       |
feedback_epoch       |
replica_lag_in_msec |
log_stream_speed_in_kib_per_second | 0
log_buffer_sequence_number | 0
oldest_read_view_trx_id |
oldest_read_view_lsn  |
pending_read_ios     | 819
```

## aurora\_ccm\_status

Displays the status of cluster cache manager.

### Syntax

```
aurora_ccm_status()
```

### Arguments

None.

### Return type

SETOF record with following columns:

- `buffers_sent_last_minute` – The number of buffers sent to the designated reader in the past minute.
- `buffers_found_last_minute` – The number of frequently access buffers during the past minute.

- `buffers_sent_last_scan` – The number of buffers sent to the designated reader during the last complete scan of the buffer cache.
- `buffers_found_last_scan` – The number of frequently accessed buffers sent during the last complete scan of the buffer cache. Buffers that are already cached on the designated reader aren't sent.
- `buffers_sent_current_scan` – The number of buffers sent during the current scan.
- `buffers_found_current_scan` – The number of frequently accessed buffers that were identified in the current scan.
- `current_scan_progress` – The number of buffers visited so far during the current scan.

## Usage notes

You can use this function to check and monitor the cluster cache management (CCM) feature. This function works only if CCM is active on your Aurora PostgreSQL DB cluster. To use this function you connect to the Write DB instance on your Aurora PostgreSQL DB cluster.

You turn on CCM for an Aurora PostgreSQL DB cluster by setting the `apg_ccm_enabled` to 1 in the cluster's custom DB cluster parameter group. To learn how, see [Configuring cluster cache management \(p. 1209\)](#).

Cluster cache management is active on an Aurora PostgreSQL DB cluster when the cluster has an Aurora Reader instance configured as follows:

- The Aurora Reader instance uses same DB instance class type and size as the cluster's Writer instance.
- The Aurora Reader instance is configured as Tier-0 for the cluster. If the cluster has more than one Reader, this is its only Tier-0 Reader.

Setting more than one Reader to Tier-0 disables CCM. When CCM is disabled, calling this function returns the following error message:

```
ERROR: Cluster Cache Manager is disabled
```

You can also the PostgreSQL `pg_buffercache` extension to analyze the buffer cache. For more information, see [pg\\_buffercache](#) in the PostgreSQL documentation.

For more information, see [Introduction to Aurora PostgreSQL cluster cache management](#).

## Examples

The following example shows the results of calling the `aurora_ccm_status` function. This first example shows CCM statistics.

```
=> SELECT * FROM aurora_ccm_status();
buffers_sent_last_minute | buffers_found_last_minute | buffers_sent_last_scan |
buffers_found_last_scan | buffers_sent_current_scan | buffers_found_current_scan |
current_scan_progress
-----+-----+-----+
-----+-----+-----+
-----+-----+-----+
          2242000 |           2242003 |         17920442 |
17923410 |           14098000 |         14100964 |
15877443 |
```

For more complete detail, you can use expanded display, as shown following:

```
\x
```

```
Expanded display is on.
SELECT * FROM aurora_ccm_status();
[ RECORD 1 ]-----+-----
buffers_sent_last_minute | 2242000
buffers_found_last_minute | 2242003
buffers_sent_last_scan | 17920442
buffers_found_last_scan | 17923410
buffers_sent_current_scan | 14098000
buffers_found_current_scan | 14100964
current_scan_progress | 15877443
```

This example shows how to check warm rate and warm percentage.

```
=> SELECT buffers_sent_last_minute * 8/60 AS warm_rate_kbps,
100 * (1.0-buffers_sent_last_scan/buffers_found_last_scan) AS warm_percent
FROM aurora_ccm_status ();
      warm_rate_kbps |      warm_percent
-----+-----
    16523 |        100.0
```

## [aurora\\_global\\_db\\_instance\\_status](#)

Displays the status of all Aurora instances, including replicas in an Aurora global DB cluster.

### Syntax

```
aurora_global_db_instance_status()
```

### Arguments

None

### Return type

SETOF record with following columns:

- **server\_id** – The identifier of the DB instance.
- **session\_id** – A unique identifier for the current session. A value of **MASTER\_SESSION\_ID** identifies the Writer (primary) DB instance.
- **aws\_region** – The AWS Region in which this global DB instance runs. For a list of Regions, see [Region availability \(p. 12\)](#).
- **durable\_lsn** – The log sequence number (LSN) made durable in storage. A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
- **highest\_lsn\_rcvd** – The highest LSN received by the DB instance from the writer DB instance.
- **feedback\_epoch** – The epoch that the DB instance uses when it generates hot standby information. A *hot standby* is a DB instance that supports connections and queries while the primary DB is in recovery or standby mode. The hot standby information includes the epoch (point in time) and other details about the DB instance that's being used as a hot standby. For more information, see [Hot Standby](#) in the PostgreSQL documentation.
- **feedback\_xmin** – The minimum (oldest) active transaction ID used by the DB instance.
- **oldest\_read\_view\_lsn** – The oldest LSN used by the DB instance to read from storage.
- **visibility\_lag\_in\_msec** – How far this DB instance is lagging behind the writer DB instance in milliseconds.

## Usage notes

This function shows replication statistics for an Aurora DB cluster. For each Aurora PostgreSQL DB instance in the cluster, the function shows a row of data that includes any cross-region replicas in a global database configuration.

You can run this function from any instance in an Aurora PostgreSQL DB cluster or an Aurora PostgreSQL global database. The function returns details about lag for all replica instances.

To learn more about monitoring lag using this function (`aurora_global_db_instance_status`) or by using `aurora_global_db_status`, see [Monitoring Aurora PostgreSQL-based Aurora global databases \(p. 203\)](#).

For more information about Aurora global databases, see [Overview of Amazon Aurora global databases \(p. 151\)](#).

To get started with Aurora global databases, see [Getting started with Amazon Aurora global databases \(p. 154\)](#) or see [Amazon Aurora FAQs](#).

## Examples

This example shows cross-region instance stats.

```
=> SELECT *
   FROM aurora_global_db_instance_status();
    server_id          |           session_id
aws_region | durable_lsn | highest_lsn_rcvd | feedback_epoch | feedback_xmin |
oldest_read_view_lsn | visibility_lag_in_msec
-----+-----+-----+-----+
-----+-----+
-----+-----+
db-119-001-instance-01          | MASTER_SESSION_ID          | eu-
west-1  | 2534560273 | [NULL] | [NULL] | [NULL] |
[NULL] | [NULL]          | [NULL]          | [NULL]          | [NULL] |

west-1  | 2534560266 | 2534560273 | 0 | 19669196 |
2534560254 | 23         | a331ffbb-d982-49ba-8973-527c96329c60 | eu-
central-1 | 2534560254 | 2534560266 | 0 | 19669196 |
2534560247 | 996        | db-119-001-global-instance-1          | e0955367-7082-43c4-b4db-70674064a9da | eu-
west-2  | 2534560254 | 2534560266 | 0 | 19669196 |
2534560247 | 14         | db-119-001-global-instance-1-eu-west-2a | 1248dc12-d3a4-46f5-a9e2-85850491a897 | eu-
west-2  | 2534560254 | 2534560266 | 0 | 19669196 |
2534560247 | 0          |
```

This example shows how to check global replica lag in milliseconds.

```
=> SELECT CASE
      WHEN 'MASTER_SESSION_ID' = session_id THEN 'Primary'
      ELSE 'Secondary'
```

```

        END AS global_role,
        aws_region,
        server_id,
        visibility_lag_in_msec
    FROM aurora_global_db_instance_status()
    ORDER BY 1, 2, 3;
        global_role | aws_region | server_id | visibility_lag_in_msec
-----+-----+-----+
Primary | eu-west-1 | db-119-001-instance-01 | [NULL]
[NULL]
Secondary | eu-central-1 | db-119-001-global-instance-1 | 13
10
Secondary | eu-west-1 | db-119-001-instance-02 | 9
Secondary | eu-west-1 | db-119-001-instance-03 | 2
Secondary | eu-west-1 | db-119-001-instance-04 | 18
Secondary | eu-west-1 | db-119-001-instance-05 | 14
Secondary | eu-west-2 | db-119-001-global-instance-1 | 13
Secondary | eu-west-2 | db-119-001-global-instance-1-eu-west-2a |

```

This example shows how to check min, max and average lag per AWS Region from the global database configuration.

```

=> SELECT 'Secondary' global_role,
        aws_region,
        min(visibility_lag_in_msec) min_lag_in_msec,
        max(visibility_lag_in_msec) max_lag_in_msec,
        round(avg(visibility_lag_in_msec),0) avg_lag_in_msec
    FROM aurora_global_db_instance_status()
    WHERE aws_region NOT IN (SELECT aws_region
                                FROM aurora_global_db_instance_status()
                                WHERE session_id='MASTER_SESSION_ID')
                                GROUP BY aws_region
UNION ALL
SELECT 'Primary' global_role,
        aws_region,
        NULL,
        NULL,
        NULL
    FROM aurora_global_db_instance_status()
    WHERE session_id='MASTER_SESSION_ID'
ORDER BY 1, 5;
        global_role | aws_region | min_lag_in_msec | max_lag_in_msec | avg_lag_in_msec
-----+-----+-----+-----+
Primary | eu-west-1 | [NULL] | [NULL] | [NULL]
Secondary | eu-central-1 | 133 | 133 | 133
Secondary | eu-west-2 | 0 | 495 | 248

```

## [aurora\\_global\\_db\\_status](#)

Displays information about various aspects of Aurora global database lag, specifically, lag of the underlying Aurora storage (so called durability lag) and lag between the recovery point objective (RPO).

This function is available for the following Aurora PostgreSQL versions:

- PostgreSQL 11.7 (Aurora PostgreSQL release 3.2) and higher versions

- PostgreSQL 10.11 (Aurora PostgreSQL release 2.4) and higher versions

When this function is used with Aurora PostgreSQL DB versions earlier than PostgreSQL 11.7 (Aurora PostgreSQL release 3.2), it returns less information than when used with PostgreSQL 11.7 and later versions. PostgreSQL 11.7 (Aurora PostgreSQL release 3.2) and higher versions returned enhanced statistics to this function.

## Syntax

```
aurora_global_db_status()
```

## Arguments

None.

## Return type

SETOF record with following columns:

- `aws_region` – The AWS Region that this DB cluster is in. For a complete listing of AWS Regions by engine, see [Regions and Availability Zones \(p. 11\)](#).
- `highest_lsn_written` – The highest log sequence number (LSN) that currently exists on this DB cluster. A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
- `durability_lag_in_msec` – The difference in the timestamp values between the `highest_lsn_written` on a secondary DB cluster and the `highest_lsn_written` on the primary DB cluster. A value of -1 identifies the primary global database of an Aurora global database.
- `rpo_lag_in_msec` – The recovery point objective (RPO) lag. The RPO lag is the time it takes for the most recent user transaction COMMIT to be stored on a secondary DB cluster after it's been stored on the primary DB cluster of an Aurora global database. A value of -1 denotes the primary global database (and thus, lag isn't relevant).

In simple terms, this metric calculates the recovery point objective for each Aurora PostgreSQL DB cluster in an Aurora global database, that is, how much data might be lost if there were an outage. As with lag, RPO is measured in time.

- `last_lag_calculation_time` – The timestamp that specifies when values were last calculated for `replication_lag_in_msec` and `rpo_lag_in_msec`. A time value such as 1970-01-01 00:00:00+00 means this is the primary global database.
- `feedback_epoch` – The epoch that the secondary DB cluster uses when it generates hot standby information. A *hot standby* is a DB instance that supports connections and queries while the primary DB is in recovery or standby mode. The hot standby information includes the epoch (point in time) and other details about the DB instance that's being used as a hot standby. For more information, see [Hot Standby](#) in the PostgreSQL documentation.
- `feedback_xmin` – The minimum (oldest) active transaction ID used by the secondary DB cluster.

## Usage notes

This function shows replication statistics for an Aurora global database. It shows one row for each DB cluster in an Aurora PostgreSQL global database. You can run this function from any instance in your Aurora PostgreSQL global database.

To evaluate Aurora global database replication lag, which is the visible data lag, see [aurora\\_global\\_db\\_instance\\_status \(p. 1346\)](#).

To learn more about using `aurora_global_db_status` and `aurora_global_db_instance_status` to monitor Aurora global database lag, see [Monitoring Aurora PostgreSQL-based Aurora global databases \(p. 203\)](#). For more information about Aurora global databases, see [Overview of Amazon Aurora global databases \(p. 151\)](#).

## Examples

This example shows how to display cross-region storage statistics.

```
=> SELECT CASE
      WHEN '-1' = durability_lag_in_msec THEN 'Primary'
      ELSE 'Secondary'
    END AS global_role,
    *
  FROM aurora_global_db_status();
global_role | aws_region | highest_lsn_written | durability_lag_in_msec | rpo_lag_in_msec
| last_lag_calculation_time | feedback_epoch | feedback_xmin
-----+-----+-----+-----+-----+
-----+-----+-----+-----+
Primary | eu-west-1 | 131031557 | -1 | -1
| 1970-01-01 00:00:00+00 | 0 | 0
Secondary | eu-west-2 | 131031554 | 410 | 0
| 2021-06-01 18:59:36.124+00 | 0 | 12640
Secondary | eu-west-3 | 131031554 | 410 | 0
| 2021-06-01 18:59:36.124+00 | 0 | 12640
```

## aurora\_list\_builtin

Lists all available Aurora PostgreSQL built-in functions, along with brief descriptions and function details.

### Syntax

```
aurora_list_builtin()
```

### Arguments

None

### Return type

SETOF record

## Examples

The following example shows results from calling the `aurora_list_builtin` function.

```
=> SELECT *
FROM aurora_list_builtin();

          Name          | Result data type | Argument data
types      | Type | Volatility | Parallel | Security |

```

## [aurora\\_replica\\_status](#)

Displays the status of all Aurora PostgreSQL reader nodes.

### Syntax

```
aurora_replica_status()
```

### Arguments

None

### Return type

SETOF record with the following columns:

- **server\_id** – The DB instance ID (identifier).
- **session\_id** – A unique identifier for the current session, returned for primary instance and reader instances as follows:
  - For the primary instance, **session\_id** is always `MASTER\_SESSION\_ID`.
  - For reader instances, **session\_id** is always the UUID (universally unique identifier) of the reader instance.
- **durable\_lsn** – The log sequence number (LSN) that's been saved in storage.
  - For the primary volume, the primary volume durable LSN (VDL) that's currently in effect.
  - For any secondary volumes, the VDL of the primary up to which the secondary has successfully been applied.

### Note

A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a transaction that's occurred later in the sequence.

- `highest_lsn_rcvd` – The highest (most recent) LSN received by the DB instance from the writer DB instance.
- `current_read_lsn` – The LSN of the most recent snapshot that's been applied to all readers.
- `cur_replay_latency_in_usecs` – The number of microseconds that it's expected to take to replay the log on the secondary.
- `active_txns` – The number of currently active transactions.
- `is_current` – Not used.
- `last_transport_error` – Last replication error code.
- `last_error_timestamp` – Timestamp of last replication error.
- `last_update_timestamp` – Timestamp of last update to replica status.
- `feedback_xmin` – The hot standby feedback\_xmin of the replica. The minimum (oldest) active transaction ID used by the DB instance.
- `feedback_epoch` – The epoch the DB instance uses when it generates hot standby information.
- `replica_lag_in_msec` – Time that reader instance lags behind writer writer instance, in milliseconds.
- `log_stream_speed_in_kib_per_second` – The log stream throughput in kilobytes per second.
- `log_buffer_sequence_number` – The log buffer sequence number.
- `oldest_read_view_trx_id` – Not used.
- `oldest_read_view_lsn` – The oldest LSN used by the DB instance to read from storage.
- `pending_read_ios` – The outstanding page reads that are still pending on replica.
- `read_ios` – The total number of page reads on replica.
- `iops` – Not used.
- `cpu` – CPU usage by the replica process. Note that this isn't CPU usage by the instance but rather the process. For information about CPU usage by the instance, see [Instance-level metrics for Amazon Aurora \(p. 531\)](#).

## Usage notes

The `aurora_replica_status` function returns values from an Aurora PostgreSQL DB cluster's replica status manager. You can use this function to obtain information about the status of replication on your Aurora PostgreSQL DB cluster, including metrics for all DB instances in your Aurora DB cluster. For example, you can do the following:

- **Get information about the type of instance (writer, reader) in the Aurora PostgreSQL DB cluster** – You can obtain this information by checking the values of the following columns:
  - `server_id` – Contains the name of the instance that you specified when you created the instance. In some cases, such as for the primary (writer) instance, the name is typically created for you by appending `-instance-1` to the name that you create for your Aurora PostgreSQL DB cluster.
  - `session_id` – The `session_id` field indicates whether the instance is a reader or a writer. For a writer instance, `session_id` is always set to "MASTER\_SESSION\_ID". For a reader instance, `session_id` is set to the UUID of the specific reader.
- **Diagnose common replication issues, such as replica lag** – Replica lag is the time in milliseconds that the page cache of a reader instance is behind that of the writer instance. This lag occurs because Aurora clusters use asynchronous replication, as described in [Replication with Amazon Aurora \(p. 73\)](#). It's shown in the `replica_lag_in_msec` column in the results returned by this function. Lag can also occur when a query is cancelled due to conflicts with recovery on a standby server. You can check

`pg_stat_database_conflicts()` to verify that such a conflict is causing the replica lag (or not). For more information, see [The Statistics Collector](#) in the *PostgreSQL documentation*. To learn more about high availability and replication, see [Amazon Aurora FAQs](#).

Amazon CloudWatch stores `replica_lag_in_msec` results over time, as the `AuroraReplicaLag` metric. For information about using CloudWatch metrics for Aurora, see [Monitoring Amazon Aurora metrics with Amazon CloudWatch \(p. 452\)](#)

To learn more about troubleshooting Aurora read replicas and restarts, see [Why did my Amazon Aurora read replica fall behind and restart?](#) in the [AWS Support Center](#).

## Examples

The following example shows how to get the replication status of all instances in an Aurora PostgreSQL DB cluster:

```
=> SELECT *
FROM aurora_replica_status();
```

The following example shows the writer instance in the `docs-lab-apg-main` Aurora PostgreSQL DB cluster:

```
=> SELECT server_id,
CASE
    WHEN 'MASTER_SESSION_ID' = session_id THEN 'writer'
    ELSE 'reader'
END AS instance_role
FROM aurora_replica_status()
WHERE session_id = 'MASTER_SESSION_ID';
server_id      | instance_role
-----+-----
db-119-001-instance-01 | writer
```

The following example lists all reader instances in a cluster:

```
=> SELECT server_id,
CASE
    WHEN 'MASTER_SESSION_ID' = session_id THEN 'writer'
    ELSE 'reader'
END AS instance_role
FROM aurora_replica_status()
WHERE session_id <> 'MASTER_SESSION_ID';
server_id      | instance_role
-----+-----
db-119-001-instance-02 | reader
db-119-001-instance-03 | reader
db-119-001-instance-04 | reader
db-119-001-instance-05 | reader
(4 rows)
```

The following example lists all instances, how far each instance is lagging behind the writer, and how long since the last update:

```
=> SELECT server_id,
CASE
    WHEN 'MASTER_SESSION_ID' = session_id THEN 'writer'
    ELSE 'reader'
END AS instance_role,
replica_lag_in_msec AS replica_lag_ms,
```

```

    round(extract (epoch FROM (SELECT age(clock_timestamp(), last_update_timestamp))) *
1000) AS last_update_age_ms
FROM aurora_replica_status()
ORDER BY replica_lag_in_msec NULLS FIRST;
server_id | instance_role | replica_lag_ms | last_update_age_ms
-----+-----+-----+
db-124-001-instance-03 | writer | [NULL] | 1756
db-124-001-instance-01 | reader | 13 | 1756
db-124-001-instance-02 | reader | 13 | 1756
(3 rows)

```

## aurora\_stat\_backend\_waits

Displays statistics for wait activity for a specific backend process.

### Syntax

```
aurora_stat_backend_waits(pid)
```

### Arguments

**pid** – The ID for the backend process. You can obtain process IDs by using the `pg_stat_activity` view.

### Return type

SETOF record with following columns:

- **type\_id** – A number that denotes the type of wait event, such as 1 for a lightweight lock (`LWLock`), 3 for a lock, or 6 for a client session, to name some examples. These values become meaningful when you join the results of this function with columns from `aurora_stat_wait_type` function, as shown in the [Examples \(p. 1354\)](#).
- **event\_id** – An identifying number for the wait event. Join this value with the columns from `aurora_stat_wait_event` to obtain meaningful event names.
- **waits** – A count of the number of waits accumulated for the specified process ID.
- **wait\_time** – Wait time in milliseconds.

### Usage notes

You can use this function to analyze specific backend (session) wait events that occurred since a connection opened. To get more meaningful information about wait event names and types, you can combine this function `aurora_stat_wait_type` and `aurora_stat_wait_event`, by using JOIN as shown in the examples.

### Examples

This example shows all waits, types, and event names for a backend process ID 3027.

```

=> SELECT type_name, event_name, waits, wait_time
      FROM aurora_stat_backend_waits(3027)
  NATURAL JOIN aurora_stat_wait_type()
  NATURAL JOIN aurora_stat_wait_event();
type_name | event_name | waits | wait_time
-----+-----+-----+
LWLock   | ProcArrayLock | 3 | 27
LWLock   | wal_insert | 423 | 16336
LWLock   | buffer_content | 11840 | 1033634

```

LWLock	lock_manager	23821   5664506
Lock	tuple	10258   152280165
Lock	transactionid	78340   1239808783
Client	ClientRead	34072   17616684
IO	ControlFileSyncUpdate	2   0
IO	ControlFileWriteUpdate	4   32
IO	RelationMapRead	2   795
IO	WALWrite	36666   98623
IO	XactSync	4867   7331963

This example shows current and cumulative wait types and wait events for all active sessions (`pg_stat_activity state <> 'idle'`) (but without the current session that's invoking the function (`pid <> pg_backend_pid()`)).

```
=> SELECT a.pid,
        a.username,
        a.app_name,
        a.current_wait_type,
        a.current_wait_event,
        a.current_state,
        wt.type_name AS wait_type,
        we.event_name AS wait_event,
        a.waits,
        a.wait_time
   FROM (SELECT pid,
                username,
                left(application_name,16) AS app_name,
                coalesce(wait_event_type,'CPU') AS current_wait_type,
                coalesce(wait_event,'CPU') AS current_wait_event,
                state AS current_state,
                (aurora_stat_backend_waits(pid)).*
          FROM pg_stat_activity
         WHERE pid <> pg_backend_pid()
           AND state <> 'idle') a
  NATURAL JOIN aurora_stat_wait_type() wt
  NATURAL JOIN aurora_stat_wait_event() we;
    pid | username | app_name | current_wait_type | current_wait_event | current_state | wait_type | wait_event | waits | wait_time
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
30099 | postgres | pgbench | Lock | transactionid | active | LWLock | wal_insert | 1937 | 29975
30099 | postgres | pgbench | Lock | transactionid | active | LWLock | buffer_content | 22903 | 760498
30099 | postgres | pgbench | Lock | transactionid | active | LWLock | lock_manager | 10012 | 223207

## aurora\_stat\_dml\_activity

Reports cumulative activity for each type of data manipulation language (DML) operation on a database in an Aurora PostgreSQL cluster.

### Syntax

```
aurora_stat_dml_activity(database_oid)
```

### Arguments

*database\_oid*

The object ID (OID) of the database in the Aurora PostgreSQL cluster.

### Return type

SETOF record

### Usage notes

The `aurora_stat_dml_activity` function is only available with Aurora PostgreSQL release 3.1 compatible with PostgreSQL engine 11.6 and later.

Use this function on Aurora PostgreSQL clusters with a large number of databases to identify which databases have more or slower DML activity, or both.

The `aurora_stat_dml_activity` function returns the number of times the operations ran and the cumulative latency in microseconds for SELECT, INSERT, UPDATE, and DELETE operations. The report includes only successful DML operations.

You can reset this statistic by using the PostgreSQL statistics access function `pg_stat_reset`. You can check the last time this statistic was reset by using the `pg_stat_get_db_stat_reset_time` function. For more information about PostgreSQL statistics access functions, see [The Statistics Collector](#) in the PostgreSQL documentation.

### Examples

The following example shows how to report DML activity statistics for the connected database.

```
--Define the oid variable from connected database by using \gset
=> SELECT oid,
        datname
   FROM pg_database
 WHERE datname=(select current_database()) \gset
```

```
=> SELECT *
   FROM aurora_stat_dml_activity(:oid);
select_count | select_latency_microsecs | insert_count | insert_latency_microsecs |
update_count | update_latency_microsecs | delete_count | delete_latency_microsecs
-----+-----+-----+-----+
      178957 |          66684115 |       171065 |        28876649 |
      519538 |         1454579206167 |        1 |           53027

-- Showing the same results with expanded display on
=> SELECT *
   FROM aurora_stat_dml_activity(:oid);
-[ RECORD 1 ]-----+
select_count | 178957
select_latency_microsecs | 66684115
insert_count | 171065
insert_latency_microsecs | 28876649
update_count | 519538
update_latency_microsecs | 1454579206167
delete_count | 1
delete_latency_microsecs | 53027
```

The following example shows DML activity statistics for all databases in the Aurora PostgreSQL cluster. This cluster has two databases, `postgres` and `mydb`. The comma-separated list corresponds with the `select_count`, `select_latency_microsecs`, `insert_count`, `insert_latency_microsecs`, `update_count`, `update_latency_microsecs`, `delete_count`, and `delete_latency_microsecs` fields.

Aurora PostgreSQL creates and uses a system database named `rdsadmin` to support administrative operations such as backups, restores, health checks, replication, and so on. These DML operations have no impact on your Aurora PostgreSQL cluster.

```
=> SELECT oid,
       datname,
       aurora_stat_dml_activity(oid)
      FROM pg_database;
oid | datname | aurora_stat_dml_activity
-----+-----+-----+
 14006 | template0 | (,,,,,,)
 16384 | rdsadmin | (2346623,1211703821,4297518,817184554,0,0,0,0)
     1 | template1 | (,,,,,,)
 14007 | postgres | (178961,66716329,171065,28876649,519538,1454579206167,1,53027)
 16401 | mydb    | (200246,64302436,200036,107101855,600000,83659417514,0,0)
```

The following example shows DML activity statistics for all databases, organized in columns for better readability.

```
SELECT db.datname,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 1), '()') AS select_count,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 2), '()') AS select_latency_microsecs,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 3), '()') AS insert_count,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 4), '()') AS insert_latency_microsecs,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 5), '()') AS update_count,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 6), '()') AS update_latency_microsecs,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 7), '()') AS delete_count,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 8), '()') AS delete_latency_microsecs
  FROM (SELECT datname,
              aurora_stat_dml_activity(oid) AS asdmla
            FROM pg_database
          ) AS db;
```

## aurora\_stat\_get\_db\_commit\_latency

Gets the cumulative commit latency in microseconds for Aurora PostgreSQL databases. *Commit latency* is measured as the time between when a client submits a commit request and when it receives the commit acknowledgement.

### Syntax

aurora_stat_get_db_commit_latency(database_oid)
---

## Arguments

### *database\_oid*

The object ID (OID) of the Aurora PostgreSQL database.

## Return type

SETOF record

## Usage notes

Amazon CloudWatch uses this function to calculate the average commit latency. For more information about Amazon CloudWatch metrics and how to troubleshoot high commit latency, see [Viewing metrics in the Amazon RDS console \(p. 449\)](#) and [Making better decisions about Amazon RDS with Amazon CloudWatch metrics](#).

You can reset this statistic by using the PostgreSQL statistics access function `pg_stat_reset`. You can check the last time this statistic was reset by using the `pg_stat_get_db_stat_reset_time` function. For more information about PostgreSQL statistics access functions, see [The Statistics Collector](#) in the PostgreSQL documentation.

## Examples

The following example gets the cumulative commit latency for each database in the `pg_database` cluster.

```
=> SELECT oid,
       datname,
       aurora_stat_get_db_commit_latency(oid)
  FROM pg_database;

   oid   |    datname    | aurora_stat_get_db_commit_latency
-----+-----+-----+
  14006 | template0   | 0
  16384 | rdsadmin    | 654387789
      1 | template1   | 0
  16401 | mydb        | 229556
  69768 | postgres     | 22011
```

The following example gets the cumulative commit latency for the currently connected database. Before calling the `aurora_stat_get_db_commit_latency` function, the example first uses `\gset` to define a variable for the `oid` argument and sets its value from the connected database.

```
--Get the oid value from the connected database before calling
aurora_stat_get_db_commit_latency
=> SELECT oid
   FROM pg_database
   WHERE datname=(SELECT current_database()) \gset
=> SELECT *
   FROM aurora_stat_get_db_commit_latency(:oid);

aurora_stat_get_db_commit_latency
-----+
 1424279160
```

The following example gets the cumulative commit latency for the `mydb` database in the `pg_database` cluster. Then, it resets this statistic by using the `pg_stat_reset` function and shows the results. Finally, it uses the `pg_stat_get_db_stat_reset_time` function to check the last time this statistic was reset.

```
=> SELECT oid,
       datname,
       aurora_stat_get_db_commit_latency(oid)
  FROM pg_database
 WHERE datname = 'mydb';

   oid  |  datname  | aurora_stat_get_db_commit_latency
-----+-----+
 16427 | mydb     |                      3320370

=> SELECT pg_stat_reset();
 pg_stat_reset
-----

=> SELECT oid,
       datname,
       aurora_stat_get_db_commit_latency(oid)
  FROM pg_database
 WHERE datname = 'mydb';
oid  |  datname  | aurora_stat_get_db_commit_latency
-----+-----+
 16427 | mydb     |                      6

=> SELECT *
   FROM pg_stat_get_db_stat_reset_time(16427);

 pg_stat_get_db_stat_reset_time
-----
2021-04-29 21:36:15.707399+00
```

## [aurora\\_stat\\_system\\_waits](#)

Reports wait event information for the Aurora PostgreSQL DB instance.

### Syntax

<code>aurora_stat_system_waits()</code>
---

### Arguments

None

### Return type

SETOF record

### Usage notes

This function returns the cumulative number of waits and cumulative wait time for each wait event generated by the DB instance that you're currently connected to.

The returned recordset includes the following fields:

- `type_id` – The ID of the type of wait event.
- `event_id` – The ID of the wait event.
- `waits` – The number of times the wait event occurred.

- `wait_time` – The total amount of time in microseconds spent waiting for this event.

Statistics returned by this function are reset when a DB instance restarts.

## Examples

The following example shows results from calling the `aurora_stat_system_waits` function.

```
=> SELECT *
   FROM aurora_stat_system_waits();
 type_id | event_id |    waits | wait_time
-----+-----+-----+-----+
      1 | 16777219 |      11 |     12864
      1 | 16777220 |      501 |    174473
      1 | 16777270 |    53171 |  23641847
      1 | 16777271 |       23 |    319668
      1 | 16777274 |       60 |    12759
.
.
.
      10 | 167772231 |  204596 | 790945212
      10 | 167772232 |       2 |     47729
      10 | 167772234 |       1 |      888
      10 | 167772235 |       2 |      64
```

The following example shows how you can use this function together with `aurora_stat_wait_event` and `aurora_stat_wait_type` to produce more readable results.

```
=> SELECT type_name,
           event_name,
           waits,
           wait_time
      FROM aurora_stat_system_waits()
 NATURAL JOIN aurora_stat_wait_event()
 NATURAL JOIN aurora_stat_wait_type();

## aurora\_stat\_wait\_event

Lists all supported wait events for Aurora PostgreSQL. For information about Aurora PostgreSQL wait events, see [Amazon Aurora PostgreSQL wait events \(p. 1395\)](#).

## Syntax

```
aurora_stat_wait_event()
```

## Arguments

None

## Return type

SETOF record with following columns:

- `type_id` – The ID of the type of wait event.
- `event_id` – The ID of the wait event.
- `type_name` – Wait type name
- `event_name` – Wait event name

## Usage notes

To see event names with event types instead of IDs, use this function together with other functions such as `aurora_stat_wait_type` and `aurora_stat_system_waits`. Wait event names returned by this function are the same as those returned by the `aurora_wait_report` function.

## Examples

The following example shows results from calling the `aurora_stat_wait_event` function.

```
=> SELECT *  
  FROM aurora_stat_wait_event();  
  
type_id | event_id | event_name  
-----+-----+-----  
 1 | 16777216 | <unassigned:0>  
 1 | 16777217 | ShmemIndexLock  
 1 | 16777218 | OidGenLock  
 1 | 16777219 | XidGenLock  
 .  
 .  
 .  
 9 | 150994945 | PgSleep  
 9 | 150994946 | RecoveryApplyDelay  
10 | 167772160 | BufFileRead

10 | 167772162 | ControlFileRead  
 .  
 .  
 .  
10 | 167772226 | WALInitWrite  
10 | 167772227 | WALRead  
10 | 167772228 | WALSync  
10 | 167772229 | WALSyncMethodAssign  
10 | 167772230 | WALWrite  
10 | 167772231 | XactSync  
 .  
 .  
 .  
11 | 184549377 | LsnAllocate
```

The following example joins `aurora_stat_wait_type` and `aurora_stat_wait_event` to return type names and event names for improved readability.

```
=> SELECT *
   FROM aurora_stat_wait_type() t
   JOIN aurora_stat_wait_event() e
     ON t.type_id = e.type_id;

+-----+-----+-----+-----+-----+
| type_id | type_name | type_id | event_id | event_name |
+-----+-----+-----+-----+-----+
| 1 | LWLock | 1 | 16777216 | <unassigned:0>
| 1 | LWLock | 1 | 16777217 | ShmemIndexLock

| 10 | IO | 10 | 167772215 | TimelineHistoryWrite
| 10 | IO | 10 | 167772216 | TwophaseFileRead
| 10 | IO | 10 | 167772217 | TwophaseFileSync
.
.
.
| 11 | LSN | 11 | 184549376 | LsnDurable
```

## aurora\_stat\_wait\_type

Lists all supported wait types for Aurora PostgreSQL.

## Syntax

```
aurora stat wait_type()
```

## Arguments

None

## Return type

SETOE record with following columns:

- `type_id` – The ID of the type of wait event.
  - `type_name` – Wait type name.

## Usage notes

To see wait event names with wait event types instead of IDs, use this function together with other functions such as `aurora_stat_wait_event` and `aurora_stat_system_waits`. Wait type names returned by this function are the same as those returned by the `aurora_wait_report` function.

## Examples

The following example shows results from calling the `aurora_stat_wait_type` function.

```
=> SELECT *  
      FROM aurora_stat_wait_type();  
type_id | type_name  
-----+-----  
     1 | LWLock  
     3 | Lock  
     4 | BufferPin  
     5 | Activity  
     6 | Client  
     7 | Extension  
     8 | IPC  
     9 | Timeout  
    10 | IO  
    11 | LSN
```

## aurora\_version

Returns the string value of the Amazon Aurora PostgreSQL-Compatible Edition version number.

### Syntax

```
aurora_version()
```

### Arguments

None

### Return type

CHAR or VARCHAR string

### Usage notes

This function displays the version of the Amazon Aurora PostgreSQL-Compatible Edition database engine. The version number is returned as a string formatted as `major.minor.patch`. For more information about Aurora PostgreSQL version numbers, see [Aurora version number \(p. 1413\)](#).

You can choose when to apply minor version upgrades by setting the maintenance window for your Aurora PostgreSQL DB cluster. To learn how, see [Maintaining an Amazon Aurora DB cluster \(p. 321\)](#).

Starting with the release of Aurora PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers follow PostgreSQL version numbers. For more information about all Aurora PostgreSQL releases, see [Amazon Aurora PostgreSQL updates](#) in the *Release Notes for Aurora PostgreSQL*.

## Examples

The following example shows the results of calling the `aurora_version` function on an Aurora PostgreSQL DB cluster running [PostgreSQL 12.7, Aurora PostgreSQL release 4.2](#) and then running the same function on a cluster running [Aurora PostgreSQL version 13.3](#).

```
=> SELECT * FROM aurora_version();  
aurora_version  
-----
```

```

4.2.2
SELECT * FROM aurora_version();
aurora_version
-----
13.3.0

```

This example shows how to use the function with various options to get more detail about the Aurora PostgreSQL version. This example has an Aurora version number that's distinct from the PostgreSQL version number.

```

=> SHOW SERVER_VERSION;
server_version
-----
12.7
(1 row)

=> SELECT * FROM aurora_version();
aurora_version
-----
4.2.2
(1 row)

=> SELECT current_setting('server_version') AS "PostgreSQL Compatibility";
PostgreSQL Compatibility
-----
12.7
(1 row)

=> SELECT version() AS "PostgreSQL Compatibility Full String";
PostgreSQL Compatibility Full String
-----
PostgreSQL 12.7 on aarch64-unknown-linux-gnu, compiled by aarch64-unknown-linux-gnu-gcc
(GCC) 7.4.0, 64-bit
(1 row)

=> SELECT 'Aurora: '
  || aurora_version()
  || ' Compatible with PostgreSQL: '
  || current_setting('server_version') AS "Instance Version";
Instance Version
-----
Aurora: 4.2.2 Compatible with PostgreSQL: 12.7
(1 row)

```

This next example uses the function with the same options in the previous example. This example doesn't have an Aurora version number that's distinct from the PostgreSQL version number.

```

=> SHOW SERVER_VERSION;
server_version
-----
13.3

=> SELECT * FROM aurora_version();
aurora_version
-----
13.3.0
=> SELECT current_setting('server_version') AS "PostgreSQL Compatibility";
PostgreSQL Compatibility
-----
13.3

```

```
=> SELECT version() AS "PostgreSQL Compatibility Full String";
PostgreSQL Compatibility Full String
-----
PostgreSQL 13.3 on x86_64-pc-linux-gnu, compiled by x86_64-pc-linux-gnu-gcc (GCC) 7.4.0,
64-bit
=> SELECT 'Aurora: '
    || aurora_version()
    || ' Compatible with PostgreSQL: '
    || current_setting('server_version') AS "Instance Version";
Instance Version
-----
Aurora: 13.3.0 Compatible with PostgreSQL: 13.3
```

## aurora\_wait\_report

This function shows wait event activity over a period of time.

### Syntax

```
aurora_wait_report([time])
```

### Arguments

*time (optional)*

The time in seconds. Default is 10 seconds.

### Return type

SETOF record with following columns:

- `type_name` – Wait type name
- `event_name` – Wait event name
- `wait` – Number of waits
- `wait_time` – Wait time in milliseconds
- `ms_per_wait` – Average milliseconds by the number of an wait
- `waits_per_xact` – Average waits by the number of one transaction
- `ms_per_xact` – Average milliseconds by the number of transactions

### Usage notes

This function is available as of Aurora PostgreSQL release 1.1 compatible with PostgreSQL 9.6.6 and higher versions.

To use this function, you need to first create the Aurora PostgreSQL `aurora_stat_utils` extension, as follows:

```
=> CREATE extension aurora_stat_utils;
CREATE EXTENSION
```

For more information about available Aurora PostgreSQL extension versions, see [Extension versions for Amazon Aurora PostgreSQL](#) in *Release Notes for Aurora PostgreSQL*.

This function calculates the instance-level wait events by comparing two snapshots of statistics data from `aurora_stat_system_waits()` function and `pg_stat_database` PostgreSQL Statistics Views.

For more information about `aurora_stat_system_waits()` and `pg_stat_database`, see [The Statistics Collector](#) in the *PostgreSQL documentation*.

When run, this function takes an initial snapshot, waits the number of seconds specified, and then takes a second snapshot. The function compares the two snapshots and returns the difference. This difference represents the instance's activity for that time interval.

On the writer instance, the function also displays the number of committed transactions and TPS (transactions per second). This function returns information at the instance level and includes all databases on the instance.

## Examples

This example shows how to create `aurora_stat_utils` extension to be able to use `aurora_log_report` function.

```
=> CREATE extension aurora_stat_utils;
CREATE EXTENSION
```

This example shows how to check wait report for 10 seconds.

```
=> SELECT *
   FROM aurora_wait_report();
NOTICE: committed 34 transactions in 10 seconds (tps 3)
 type_name | event_name      | waits | wait_time | ms_per_wait | waits_per_xact |

## Amazon Aurora PostgreSQL parameters

You manage your Amazon Aurora DB cluster in the same way that you manage Amazon RDS DB instances, by using parameters in a DB parameter group. However, Amazon Aurora differs from Amazon RDS in that an Aurora DB cluster has multiple DB instances. Some of the parameters that you use to manage your Amazon Aurora DB cluster apply to the entire cluster, while other parameters apply only to a given DB instance in the DB cluster, as follows:

- **DB cluster parameter group** – A DB cluster parameter group contains the set of engine configuration parameters that apply throughout the Aurora DB cluster. For example, cluster cache management is a feature of an Aurora DB cluster that's controlled by the `apg_ccm_enabled` parameter which is part of the DB cluster parameter group. The DB cluster parameter group also contains default settings for the DB parameter group for the DB instances that make up the cluster.
- **DB parameter group** – A DB parameter group is the set of engine configuration values that apply to a specific DB instance of that engine type. The DB parameter groups for the PostgreSQL DB engine are used by an RDS for PostgreSQL DB instance, and Aurora PostgreSQL DB cluster. These configuration settings apply to properties that can vary among the DB instances within an Aurora cluster, such as the sizes for memory buffers.

You manage cluster-level parameters in DB cluster parameter groups. You manage instance-level parameters in DB parameter groups. You can manage parameters using the Amazon RDS console, the AWS CLI, or the Amazon RDS API. There are separate commands for managing cluster-level parameters and instance-level parameters.

- To manage cluster-level parameters in a DB cluster parameter group, use the [modify-db-cluster-parameter-group](#) AWS CLI command.
- To manage instance-level parameters in a DB parameter group for a DB instance in a DB cluster, use the [modify-db-parameter-group](#) AWS CLI command.

To learn more about the AWS CLI, see [Using the AWS CLI in the AWS Command Line Interface User Guide](#).

For more information about parameter groups, see [Working with parameter groups \(p. 215\)](#).

## Viewing Aurora PostgreSQL DB cluster and DB parameters

You can view all available default parameter groups for RDS for PostgreSQL DB instances and for Aurora PostgreSQL DB clusters in the AWS Management Console. The default parameter groups for all DB engines and DB cluster types and versions are listed for each AWS Region. Any custom parameter groups are also listed.

Rather than viewing in the AWS Management Console, you can also list parameters contained in DB cluster parameter groups and DB parameter groups by using the AWS CLI or the Amazon RDS API. For example, to list parameters in a DB cluster parameter group you use the [describe-db-cluster-parameters](#) AWS CLI command as follows:

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name default.aurora-postgresql12
```

The command returns detailed JSON descriptions of each parameter. To reduce the amount of information returned, you can specify what you want by using the `--query` option. For example, you can get the parameter name, its description, and allowed values for the default Aurora PostgreSQL 12 DB cluster parameter group as follows:

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name default.aurora-postgresql12 \
  --query 'Parameters[]'.
[{"ParameterName":ParameterName, "Description":Description, "ApplyType":ApplyType, "AllowedValues":AllowedValues}]
```

For Windows:

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name default.aurora-postgresql12 ^
  --query "Parameters[]".
[{"ParameterName":ParameterName, "Description":Description, "ApplyType":ApplyType, "AllowedValues":AllowedValues}]
```

An Aurora DB cluster parameter group includes the DB instance parameter group and default values for a given Aurora DB engine. You can get the list of DB parameters from the same default Aurora PostgreSQL default parameter group by using the [describe-db-parameters](#) AWS CLI command as shown following.

For Linux, macOS, or Unix:

```
aws rds describe-db-parameters --db-parameter-group-name default.aurora-postgresql12 \
  --query 'Parameters[]'.
[{"ParameterName":ParameterName, "Description":Description, "ApplyType":ApplyType, "AllowedValues":AllowedValues}]
```

For Windows:

```
aws rds describe-db-parameters --db-parameter-group-name default.aurora-postgresql12 ^
```

```
--query "Parameters[]."  
[{"ParameterName":ParameterName,Description:Description,ApplyType:ApplyType,AllowedValues:AllowedValues}]
```

The preceding commands return lists of parameters from the DB cluster or DB parameter group with descriptions and other details specified in the query. Following is an example response.

```
[  
  [  
    {  
      "ParameterName": "apg_enable_batch_mode_function_execution",  
      "ApplyType": "dynamic",  
      "Description": "Enables batch-mode functions to process sets of rows at a  
time.",  
      "AllowedValues": "0,1"  
    }  
  ],  
  [  
    {  
      "ParameterName": "apg_enable_correlated_any_transform",  
      "ApplyType": "dynamic",  
      "Description": "Enables the planner to transform correlated ANY Sublink (IN/NOT  
IN subquery) to JOIN when possible.",  
      "AllowedValues": "0,1"  
    }  
  ],...  
]
```

Following are tables containing values for the default DB cluster parameter and DB parameter for Aurora PostgreSQL version 13.

## Aurora PostgreSQL cluster-level parameters

The following table lists some of parameters available in the default DB cluster parameter group for Aurora PostgreSQL version 13. If you create an Aurora PostgreSQL DB cluster without specifying your own custom DB parameter group, your DB cluster is created using the default Aurora DB cluster parameter group for the version chosen, such as `default.aurora-postgresql13`, `default.aurora-postgresql12`, and so on.

**Note**

All parameters in the following table are *dynamic* unless otherwise noted in the description.

For a listing of the DB instance parameters for this same default DB cluster parameter group, see [Aurora PostgreSQL instance-level parameters \(p. 1384\)](#).

Parameter name	Description
<code>ansi_constraint_trigger_ordering</code>	Change the firing order of constraint triggers to be compatible with the ANSI SQL standard.
<code>ansi_force_foreign_key_checks</code>	Ensure referential actions such as cascaded delete or cascaded update will always occur regardless of the various trigger contexts that exist for the action.
<code>ansi_qualified_update_set_target</code>	Support table and schema qualifiers in UPDATE ... SET statements.
<code>apg_ccm_enabled</code>	Enable or disable cluster cache management for the cluster.
<code>apg_enable_batch_mode_function_execution</code>	Enables batch-mode functions to process sets of rows at a time.
<code>apg_enable_correlated_any_transform</code>	Enables the planner to transform correlated ANY Sublink (IN/NOT IN subquery) to JOIN when possible.
<code>apg_enable_function_migration</code>	Enables the planner to migrate eligible scalar functions to the FROM clause.
<code>apg_enable_not_in_transform</code>	Enables the planner to transform NOT IN subquery to ANTI JOIN when possible.
<code>apg_enable_remove_redundant_inner_joins</code>	Enables the planner to remove redundant inner joins.
<code>apg_enable_semijoin_push_down</code>	Enables the use of semijoin filters for hash joins.
<code>apg_plan_mgmt.capture_plan_baselines</code>	Capture plan baseline mode. manual - enable plan capture for any SQL statement off - disable plan capture automatic - enable plan capture for statements in pg_stat_statements that satisfy the eligibility criteria.
<code>apg_plan_mgmt.max_databases</code>	Static. Sets the maximum number of databases that may manage queries using apg_plan_mgmt.
<code>apg_plan_mgmt.max_plans</code>	Static. Sets the maximum number of plans that may be cached by apg_plan_mgmt.

Parameter name	Description
<code>apg_plan_mgmt.plan_retention_period</code>	Static. Maximum number of days since a plan was last_used before a plan will be automatically deleted.
<code>apg_plan_mgmt.unapproved_plan_execution_limit</code>	<del>Estimated total plan cost below which an Unapproved plan will be executed.</del>
<code>apg_plan_mgmt.use_plan_baselines</code>	Use only approved or fixed plans for managed statements.
<code>array_nulls</code>	Enable input of NULL elements in arrays.
<code>authentication_timeout</code>	(s) Sets the maximum allowed time to complete client authentication.
<code>auto_explain.log_analyze</code>	Use EXPLAIN ANALYZE for plan logging.
<code>auto_explain.log_buffers</code>	Log buffers usage.
<code>auto_explain.log_format</code>	EXPLAIN format to be used for plan logging.
<code>auto_explain.log_min_duration</code>	Sets the minimum execution time above which plans will be logged.
<code>auto_explain.log_nested_statements</code>	Log nested statements.
<code>auto_explain.log_timing</code>	Collect timing data not just row counts.
<code>auto_explain.log_triggers</code>	Include trigger statistics in plans.
<code>auto_explain.log_verbose</code>	Use EXPLAIN VERBOSE for plan logging.
<code>auto_explain.sample_rate</code>	Fraction of queries to process.
<code>autovacuum</code>	Starts the autovacuum subprocess.
<code>autovacuum_analyze_scale_factor</code>	Number of tuple inserts updates or deletes prior to analyze as a fraction of reltuples.
<code>autovacuum_analyze_threshold</code>	Minimum number of tuple inserts updates or deletes prior to analyze.
<code>autovacuum_freeze_max_age</code>	Static. Age at which to autovacuum a table to prevent transaction ID wraparound.
<code>autovacuum_max_workers</code>	Static. Sets the maximum number of simultaneously running autovacuum worker processes.
<code>autovacuum_multixact_freeze_max_age</code>	Static. Multixact age at which to autovacuum a table to prevent multixact wraparound.
<code>autovacuum_naptime</code>	(s) Time to sleep between autovacuum runs.
<code>autovacuum_vacuum_cost_delay</code>	(ms) Vacuum cost delay in milliseconds for autovacuum.
<code>autovacuum_vacuum_cost_limit</code>	Vacuum cost amount available before napping for autovacuum.

Parameter name	Description
<code>autovacuum_vacuum_insert_scale_factor</code>	Number of tuple inserts prior to vacuum as a fraction of <code>reltuples</code> .
<code>autovacuum_vacuum_insert_threshold</code>	Minimum number of tuple inserts prior to vacuum or -1 to disable insert vacuums.
<code>autovacuum_vacuum_scale_factor</code>	Number of tuple updates or deletes prior to vacuum as a fraction of <code>reltuples</code> .
<code>autovacuum_vacuum_threshold</code>	Minimum number of tuple updates or deletes prior to vacuum.
<code>autovacuum_work_mem</code>	(kB) Sets the maximum memory to be used by each autovacuum worker process.
<code>babelfishpg_tsql.default_locale</code>	Static. Default locale to be used for collations created by <code>CREATE COLLATION</code> .
<code>babelfishpg_tds.port</code>	Static. Sets the TDS TCP port the server listens on.
<code>babelfishpg_tds.tds_debug_log_level</code>	Sets logging level in TDS 0 disables logging
<code>babelfishpg_tds.tds_default_numeric_precision</code>	Sets the default precision of numeric type to be sent in the TDS column metadata if the engine does not specify one.
<code>babelfishpg_tds.tds_default_numeric_scale</code>	Sets the default scale of numeric type to be sent in the TDS column metadata if the engine does not specify one.
<code>babelfishpg_tds.tds_default_packet_size</code>	Sets the default packet size for all the SQL Server clients being connected
<code>babelfishpg_tds.tds_default_protocol_version</code>	Sets a default TDS protocol version for all the clients being connected
<code>babelfishpg_tds.tds_ssl_encrypt</code>	Sets the SSL Encryption option
<code>babelfishpg_tds.tds_ssl_max_protocol_version</code>	Sets the maximum SSL/TLS protocol version to use for tds session.
<code>babelfishpg_tds.tds_ssl_min_protocol_version</code>	Sets the minimum SSL/TLS protocol version to use for tds session.
<code>babelfishpg_tsql.migration_mode</code>	Static. Defines if multiple user databases are supported
<code>backend_flush_after</code>	(8Kb) Number of pages after which previously performed writes are flushed to disk.
<code>backslash_quote</code>	Sets whether \\" is allowed in string literals.
<code>bytea_output</code>	Sets the output format for bytea.
<code>check_function_bodies</code>	Check function bodies during <code>CREATE FUNCTION</code> .
<code>client_min_messages</code>	Sets the message levels that are sent to the client.

Parameter name	Description
<code>constraint_exclusion</code>	Enables the planner to use constraints to optimize queries.
<code>cpu_index_tuple_cost</code>	Sets the planners estimate of the cost of processing each index entry during an index scan.
<code>cpu_operator_cost</code>	Sets the planners estimate of the cost of processing each operator or function call.
<code>cpu_tuple_cost</code>	Sets the planners estimate of the cost of processing each tuple (row).
<code>cron.log_run</code>	Static. Log all jobs runs into the <code>job_run_details</code> table
<code>cron.log_statement</code>	Static. Log all cron statements prior to execution.
<code>cron.max_running_jobs</code>	Static. Maximum number of jobs that can run concurrently.
<code>cursor_tuple_fraction</code>	Sets the planners estimate of the fraction of a cursors rows that will be retrieved.
<code>db_user_namespace</code>	Enables per-database user names.
<code>deadlock_timeout</code>	(ms) Sets the time to wait on a lock before checking for deadlock.
<code>debug_pretty_print</code>	Indents parse and plan tree displays.
<code>debug_print_parse</code>	Logs each querys parse tree.
<code>debug_print_plan</code>	Logs each querys execution plan.
<code>debug_print_rewritten</code>	Logs each querys rewritten parse tree.
<code>default_statistics_target</code>	Sets the default statistics target.
<code>default_transaction_deferrable</code>	Sets the default deferrable status of new transactions.
<code>default_transaction_isolation</code>	Sets the transaction isolation level of each new transaction.
<code>default_transaction_read_only</code>	Sets the default read-only status of new transactions.
<code>effective_cache_size</code>	(8kB) Sets the planners assumption about the size of the disk cache.
<code>effective_io_concurrency</code>	Number of simultaneous requests that can be handled efficiently by the disk subsystem.
<code>enable_bitmapscan</code>	Enables the planners use of bitmap-scan plans.
<code>enable_gathermerge</code>	Enables the planners use of gather merge plans.
<code>enable_hashagg</code>	Enables the planners use of hashed aggregation plans.

Parameter name	Description
enable_hashjoin	Enables the planners use of hash join plans.
enable_incremental_sort	Enables the planners use of incremental sort steps.
enable_indexonlyscan	Enables the planners use of index-only-scan plans.
enable_indexscan	Enables the planners use of index-scan plans.
enable_material	Enables the planners use of materialization.
enable_mergejoin	Enables the planners use of merge join plans.
enable_nestloop	Enables the planners use of nested-loop join plans.
enable_parallel_append	Enables the planners use of parallel append plans.
enable_parallel_hash	Enables the planners user of parallel hash plans.
enable_partition_pruning	Enable plan-time and run-time partition pruning.
enable_partitionwise_aggregate	Enables partitionwise aggregation and grouping.
enable_partitionwise_join	Enables partitionwise join.
enable_seqscan	Enables the planners use of sequential-scan plans.
enable_sort	Enables the planners use of explicit sort steps.
enable_tidscan	Enables the planners use of TID scan plans.
escape_string_warning	Warn about backslash escapes in ordinary string literals.
exit_on_error	Terminate session on any error.
extra_float_digits	Sets the number of digits displayed for floating-point values.
force_parallel_mode	Forces use of parallel query facilities.
fromCollapse_limit	Sets the FROM-list size beyond which subqueries are not collapsed.
geqo	Enables genetic query optimization.
geqo_effort	GEQO: effort is used to set the default for other GEQO parameters.
geqo_generations	GEQO: number of iterations of the algorithm.
geqo_pool_size	GEQO: number of individuals in the population.
geqo_seed	GEQO: seed for random path selection.
geqo_selection_bias	GEQO: selective pressure within the population.
geqo_threshold	Sets the threshold of FROM items beyond which GEQO is used.

Parameter name	Description
gin_fuzzy_search_limit	Sets the maximum allowed result for exact search by GIN.
gin_pending_list_limit	(kB) Sets the maximum size of the pending list for GIN index.
hash_mem_multiplier	Multiple of work_mem to use for hash tables.
hot_standby_feedback	Allows feedback from a hot standby to the primary that will avoid query conflicts.
huge_pages	Static. Use of huge pages on Linux.
idle_in_transaction_session_timeout	(ms) Sets the maximum allowed duration of any idling transaction.
intervalstyle	Sets the display format for interval values.
joinCollapse_limit	Sets the FROM-list size beyond which JOIN constructs are not flattened.
lo_compat_privileges	Enables backward compatibility mode for privilege checks on large objects.
log_autovacuum_min_duration	(ms) Sets the minimum execution time above which autovacuum actions will be logged.
log_connections	Logs each successful connection.
log_destination	Sets the destination for server log output.
log_disconnections	Logs end of a session including duration.
log_duration	Logs the duration of each completed SQL statement.
log_error_verbosity	Sets the verbosity of logged messages.
log_executor_stats	Writes executor performance statistics to the server log.
log_filename	Sets the file name pattern for log files.
log_hostname	Logs the host name in the connection logs.
log_lock_waits	Logs long lock waits.
log_min_duration_sample	(ms) Sets the minimum execution time above which a sample of statements will be logged. Sampling is determined by log_statement_sample_rate.
log_min_duration_statement	(ms) Sets the minimum execution time above which statements will be logged.
log_min_error_statement	Causes all statements generating error at or above this level to be logged.
log_min_messages	Sets the message levels that are logged.

Parameter name	Description
<code>log_parameter_max_length</code>	(B) When logging statements limit logged parameter values to first N bytes.
<code>log_parameter_max_length_on_error</code>	(B) When reporting an error limit logged parameter values to first N bytes.
<code>log_parser_stats</code>	Writes parser performance statistics to the server log.
<code>log_planner_stats</code>	Writes planner performance statistics to the server log.
<code>log_replication_commands</code>	Logs each replication command.
<code>log_rotation_age</code>	(min) Automatic log file rotation will occur after N minutes.
<code>log_rotation_size</code>	(kB) Automatic log file rotation will occur after N kilobytes.
<code>log_statement</code>	Sets the type of statements logged.
<code>log_statement_sample_rate</code>	Fraction of statements exceeding <code>log_min_duration_sample</code> to be logged.
<code>log_statement_stats</code>	Writes cumulative performance statistics to the server log.
<code>log_temp_files</code>	(kB) Log the use of temporary files larger than this number of kilobytes.
<code>log_transaction_sample_rate</code>	Set the fraction of transactions to log for new transactions.
<code>log_truncate_on_rotation</code>	Truncate existing log files of same name during log rotation.
<code>logging_collector</code>	Static. Start a subprocess to capture stderr output and/or csvlogs into log files.
<code>logical_decoding_work_mem</code>	(kB) This much memory can be used by each internal reorder buffer before spilling to disk.
<code>maintenance_io_concurrency</code>	A variant of <code>effective_io_concurrency</code> that is used for maintenance work.
<code>maintenance_work_mem</code>	(kB) Sets the maximum memory to be used for maintenance operations.
<code>max_connections</code>	Static. Sets the maximum number of concurrent connections.
<code>max_files_per_process</code>	Static. Sets the maximum number of simultaneously open files for each server process.
<code>max_locks_per_transaction</code>	Static. Sets the maximum number of locks per transaction.

Parameter name	Description
<code>max_logical_replication_workers</code>	Static. Maximum number of logical replication worker processes.
<code>max_parallel_maintenance_workers</code>	Sets the maximum number of parallel processes per maintenance operation.
<code>max_parallel_workers</code>	Sets the maximum number of parallel workers than can be active at one time.
<code>max_parallel_workers_per_gather</code>	Sets the maximum number of parallel processes per executor node.
<code>max_pred_locks_per_page</code>	Sets the maximum number of predicate-locked tuples per page.
<code>max_pred_locks_per_relation</code>	Sets the maximum number of predicate-locked pages and tuples per relation.
<code>max_pred_locks_per_transaction</code>	Static. Sets the maximum number of predicate locks per transaction.
<code>max_prepared_transactions</code>	Static. Sets the maximum number of simultaneously prepared transactions.
<code>max_replication_slots</code>	Static. Sets the maximum number of replication slots that the server can support.
<code>max_slot_wal_keep_size</code>	(MB) Replication slots will be marked as failed and segments released for deletion or recycling if this much space is occupied by WAL on disk.
<code>max_stack_depth</code>	(kB) Sets the maximum stack depth in kilobytes.
<code>max_standby_streaming_delay</code>	(ms) Sets the maximum delay before canceling queries when a hot standby server is processing streamed WAL data.
<code>max_sync_workers_per_subscription</code>	Maximum number of synchronization workers per subscription
<code>max_wal_senders</code>	Static. Sets the maximum number of simultaneously running WAL sender processes.
<code>max_worker_processes</code>	Static. Sets the maximum number of concurrent worker processes.
<code>min_parallel_index_scan_size</code>	(8kB) Sets the minimum amount of index data for a parallel scan.
<code>min_parallel_table_scan_size</code>	(8kB) Sets the minimum amount of table data for a parallel scan.
<code>old_snapshot_threshold</code>	Static. (min) Time before a snapshot is too old to read pages changed after the snapshot was taken.
<code>operator_precedence_warning</code>	Emit a warning for constructs that changed meaning since PostgreSQL 9.4.

Parameter name	Description
parallel_leader_participation	Controls whether Gather and Gather Merge also run subplans.
parallel_setup_cost	Sets the planners estimate of the cost of starting up worker processes for parallel query.
parallel_tuple_cost	Sets the planners estimate of the cost of passing each tuple (row) from worker to master backend.
password_encryption	Encrypt passwords.
pg_bigm.enable_recheck	It specifies whether to perform Recheck which is an internal process of full text search.
pg_bigm.gin_key_limit	It specifies the maximum number of 2-grams of the search keyword to be used for full text search.
pg_hint_plan.debug_print	Logs results of hint parsing.
pg_hint_plan.enable_hint	Force planner to use plans specified in the hint comment preceding to the query.
pg_hint_plan.enable_hint_table	Force planner to not get hint by using table lookups.
pg_hint_plan.message_level	Message level of debug messages.
pg_hint_plan.parse_messages	Message level of parse errors.
pg_prewarm.autoprewarm	Starts the autoprewarm worker.
pg_prewarm.autoprewarm_interval	Sets the interval between dumps of shared buffers
pg_stat_statements.max	Static. Sets the maximum number of statements tracked by pg_stat_statements.
pg_stat_statements.save	Save pg_stat_statements statistics across server shutdowns.
pg_stat_statements.track	Selects which statements are tracked by pg_stat_statements.
pg_stat_statements.track_planning	Selects whether planning duration is tracked by pg_stat_statements.
pg_stat_statements.track_utility	Selects whether utility commands are tracked by pg_stat_statements.
pgaudit.log	Specifies which classes of statements will be logged by session audit logging.
pgaudit.log_catalog	Specifies that session logging should be enabled in the case where all relations in a statement are in pg_catalog.
pgaudit.log_level	Specifies the log level that will be used for log entries.

Parameter name	Description
<code>pgaudit.log_parameter</code>	Specifies that audit logging should include the parameters that were passed with the statement.
<code>pgaudit.log_relation</code>	Specifies whether session audit logging should create a separate log entry for each relation (TABLE VIEW etc.) referenced in a SELECT or DML statement.
<code>pgaudit.log_statement_once</code>	Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.
<code>pgaudit.role</code>	Specifies the master role to use for object audit logging.
<code>pglogical.batch_inserts</code>	Static. Batch inserts if possible
<code>pglogical.conflict_log_level</code>	Sets log level used for logging resolved conflicts.
<code>pglogical.conflict_resolution</code>	Sets method used for conflict resolution for resolvable conflicts.
<code>pglogical.synchronous_commit</code>	Static. pglogical specific synchronous commit value
<code>pglogical.use_spi</code>	Use SPI instead of low-level API for applying changes
<code>plan_cache_mode</code>	Controls the planner selection of custom or generic plan.
<code>postgis.gdal_enabled_drivers</code>	Static. Enable or disable GDAL drivers used with PostGIS in Postgres 9.3.5 and above.
<code>quote_all_identifiers</code>	When generating SQL fragments quote all identifiers.
<code>random_page_cost</code>	Sets the planners estimate of the cost of a nonsequentially fetched disk page.
<code>rdkit.do_chiral_sss</code>	Should stereochemistry be taken into account in substructure matching. If false no stereochemistry information is used in substructure matches.
<code>rds.adaptive_autovacuum</code>	RDS parameter to enable/disable adaptive autovacuum.
<code>rds.babelfish_status</code>	Static. RDS parameter to enable/disable Babelfish for Aurora PostgreSQL.
<code>rds.enable_plan_management</code>	Static. Enable or disable the apg_plan_mgmt extension.
<code>rds.force_admin_logging_level</code>	See log messages for RDS admin user actions in customer databases.

Parameter name	Description
rds.force_autovacuum_logging_level	See log messages related to autovacuum operations.
rds.force_ssl	Force SSL connections.
rds.global_db_rpo	(s) Recovery point objective threshold in seconds that blocks user commits when it is violated.
rds.log_retention_period	Amazon RDS will delete PostgreSQL log that are older than N minutes.
rds.logical_replication	Static. Enables logical decoding.
rds.pg_stat_ramdisk_size	Static. Size of the stats ramdisk in MB. A nonzero value will setup the ramdisk.
rds.rds_superuser_reserved_connections	Static. Sets the number of connection slots reserved for rds_superusers.
rds.restrict_password_commands	Static. Restricts password-related commands to members of rds_password
restart_after_crash	Reinitialize server after backend crash.
row_security	Enable row security.
seq_page_cost	Sets the planners estimate of the cost of a sequentially fetched disk page.
session_replication_role	Sets the sessions behavior for triggers and rewrite rules.
shared_buffers	(8kB) Sets the number of shared memory buffers used by the server.
shared_preload_libraries	Static. Lists shared libraries to preload into server.
update_process_title	Updates the process title to show the active SQL command.
vacuum_cleanup_index_scale_factor	Number of tuple inserts prior to index cleanup as a fraction of reltuples.
vacuum_cost_delay	(ms) Vacuum cost delay in milliseconds.
vacuum_cost_limit	Vacuum cost amount available before napping.
vacuum_cost_page_dirty	Vacuum cost for a page dirtied by vacuum.
vacuum_cost_page_hit	Vacuum cost for a page found in the buffer cache.
vacuum_cost_page_miss	Vacuum cost for a page not found in the buffer cache.
vacuum_defer_cleanup_age	Number of transactions by which VACUUM and HOT cleanup should be deferred if any.
vacuum_freeze_min_age	Minimum age at which VACUUM should freeze a table row.

Parameter name	Description
<code>vacuum_freeze_table_age</code>	Age at which VACUUM should scan whole table to freeze tuples.
<code>vacuum_multixact_freeze_min_age</code>	Minimum age at which VACUUM should freeze a MultiXactId in a table row.
<code>vacuum_multixact_freeze_table_age</code>	Multixact age at which VACUUM should scan whole table to freeze tuples.
<code>wal_buffers</code>	Static. (8kB) Sets the number of disk-page buffers in shared memory for WAL.
<code>wal_receiver_create_temp_slot</code>	Sets whether a WAL receiver should create a temporary replication slot if no permanent slot is configured.
<code>wal_receiver_status_interval</code>	(s) Sets the maximum interval between WAL receiver status reports to the primary.
<code>wal_receiver_timeout</code>	(ms) Sets the maximum wait time to receive data from the primary.
<code>wal_sender_timeout</code>	(ms) Sets the maximum time to wait for WAL replication.
<code>work_mem</code>	(kB) Sets the maximum memory to be used for query workspaces.

## Aurora PostgreSQL instance-level parameters

The following table shows all of the parameters that apply to a specific DB instance in an Aurora PostgreSQL DB cluster. This list was generated by running the [describe-db-parameters](#) AWS CLI command with `default.aurora-postgresql13` for the `--db-parameter-group-name` value.

**Note**

All parameters in the following table are *dynamic* unless otherwise noted in the description.

For a listing of the DB cluster parameters for this same default DB parameter group, see [Aurora PostgreSQL cluster-level parameters \(p. 1372\)](#).

Parameter name	Description
<code>apg_enable_batch_mode_function_execution</code>	Enables batch-mode functions to process sets of rows at a time.
<code>apg_enable_correlated_any_transform</code>	Enables the planner to transform correlated ANY Sublink (IN/NOT IN subquery) to JOIN when possible.
<code>apg_enable_function_migration</code>	Enables the planner to migrate eligible scalar functions to the FROM clause.
<code>apg_enable_not_in_transform</code>	Enables the planner to transform NOT IN subquery to ANTI JOIN when possible.
<code>apg_enable_remove_redundant_inner_joins</code>	Enables the planner to remove redundant inner joins.
<code>apg_enable_semijoin_push_down</code>	Enables the use of semijoin filters for hash joins.
<code>apg_plan_mgmt.capture_plan_baselines</code>	Capture plan baseline mode. manual - enable plan capture for any SQL statement, off - disable plan capture, automatic - enable plan capture for statements in pg_stat_statements that satisfy the eligibility criteria.
<code>apg_plan_mgmt.max_databases</code>	Static. Sets the maximum number of databases that may manage queries using apg_plan_mgmt.
<code>apg_plan_mgmt.max_plans</code>	Static. Sets the maximum number of plans that may be cached by apg_plan_mgmt.
<code>apg_plan_mgmt.plan_retention_period</code>	Static. Maximum number of days since a plan was last_used before a plan will be automatically deleted.
<code>apg_plan_mgmt.unapproved_plan_execution_limit</code>	Estimated total plan cost below which an Unapproved plan will be executed.
<code>apg_plan_mgmt.use_plan_baselines</code>	Use only approved or fixed plans for managed statements.
<code>application_name</code>	Sets the application name to be reported in statistics and logs.
<code>authentication_timeout</code>	(s) Sets the maximum allowed time to complete client authentication.

Parameter name	Description
auto_explain.log_analyze	Use EXPLAIN ANALYZE for plan logging.
auto_explain.log_buffers	Log buffers usage.
auto_explain.log_format	EXPLAIN format to be used for plan logging.
auto_explain.log_min_duration	Sets the minimum execution time above which plans will be logged.
auto_explain.log_nested_statements	Log nested statements.
auto_explain.log_timing	Collect timing data, not just row counts.
auto_explain.log_triggers	Include trigger statistics in plans.
auto_explain.log_verbose	Use EXPLAIN VERBOSE for plan logging.
auto_explain.sample_rate	Fraction of queries to process.
babelfishpg_tds.listen_addresses	Static. Sets the host name or IP address(es) to listen TDS to.
babelfishpg_tds.tds_debug_log_level	Sets logging level in TDS, 0 disables logging
backend_flush_after	(8Kb) Number of pages after which previously performed writes are flushed to disk.
bytea_output	Sets the output format for bytea.
check_function_bodies	Check function bodies during CREATE FUNCTION.
client_min_messages	Sets the message levels that are sent to the client.
config_file	Static. Sets the servers main configuration file.
constraint_exclusion	Enables the planner to use constraints to optimize queries.
cpu_index_tuple_cost	Sets the planners estimate of the cost of processing each index entry during an index scan.
cpu_operator_cost	Sets the planners estimate of the cost of processing each operator or function call.
cpu_tuple_cost	Sets the planners estimate of the cost of processing each tuple (row).
cron.database_name	Static. Sets the database to store pg_cron metadata tables
cron.log_run	Static. Log all jobs runs into the job_run_details table
cron.log_statement	Static. Log all cron statements prior to execution.
cron.max_running_jobs	Static. Maximum number of jobs that can run concurrently.
cron.use_background_workers	Static. Enables background workers for pg_cron

Parameter name	Description
<code>cursor_tuple_fraction</code>	Sets the planners estimate of the fraction of a cursors rows that will be retrieved.
<code>db_user_namespace</code>	Enables per-database user names.
<code>deadlock_timeout</code>	(ms) Sets the time to wait on a lock before checking for deadlock.
<code>debug_pretty_print</code>	Indents parse and plan tree displays.
<code>debug_print_parse</code>	Logs each querys parse tree.
<code>debug_print_plan</code>	Logs each querys execution plan.
<code>debug_print_rewritten</code>	Logs each querys rewritten parse tree.
<code>default_statistics_target</code>	Sets the default statistics target.
<code>default_transaction_deferrable</code>	Sets the default deferrable status of new transactions.
<code>default_transaction_isolation</code>	Sets the transaction isolation level of each new transaction.
<code>default_transaction_read_only</code>	Sets the default read-only status of new transactions.
<code>effective_cache_size</code>	(8kB) Sets the planners assumption about the size of the disk cache.
<code>effective_ioConcurrency</code>	Number of simultaneous requests that can be handled efficiently by the disk subsystem.
<code>enable_bitmapscan</code>	Enables the planners use of bitmap-scan plans.
<code>enable_gathermerge</code>	Enables the planners use of gather merge plans.
<code>enable_hashagg</code>	Enables the planners use of hashed aggregation plans.
<code>enable_hashjoin</code>	Enables the planners use of hash join plans.
<code>enable_incremental_sort</code>	Enables the planners use of incremental sort steps.
<code>enable_indexonlyscan</code>	Enables the planners use of index-only-scan plans.
<code>enable_indexscan</code>	Enables the planners use of index-scan plans.
<code>enable_material</code>	Enables the planners use of materialization.
<code>enable_mergejoin</code>	Enables the planners use of merge join plans.
<code>enable_nestloop</code>	Enables the planners use of nested-loop join plans.
<code>enable_parallel_append</code>	Enables the planners use of parallel append plans.
<code>enable_parallel_hash</code>	Enables the planners user of parallel hash plans.

Parameter name	Description
<code>enable_partition_pruning</code>	Enable plan-time and run-time partition pruning.
<code>enable_partitionwise_aggregate</code>	Enables partitionwise aggregation and grouping.
<code>enable_partitionwise_join</code>	Enables partitionwise join.
<code>enable_seqscan</code>	Enables the planners use of sequential-scan plans.
<code>enable_sort</code>	Enables the planners use of explicit sort steps.
<code>enable_tidscan</code>	Enables the planners use of TID scan plans.
<code>escape_string_warning</code>	Warn about backslash escapes in ordinary string literals.
<code>exit_on_error</code>	Terminate session on any error.
<code>force_parallel_mode</code>	Forces use of parallel query facilities.
<code>fromCollapse_limit</code>	Sets the FROM-list size beyond which subqueries are not collapsed.
<code>geqo</code>	Enables genetic query optimization.
<code>geqo_effort</code>	GEQO: effort is used to set the default for other GEQO parameters.
<code>geqo_generations</code>	GEQO: number of iterations of the algorithm.
<code>geqo_pool_size</code>	GEQO: number of individuals in the population.
<code>geqo_seed</code>	GEQO: seed for random path selection.
<code>geqo_selection_bias</code>	GEQO: selective pressure within the population.
<code>geqo_threshold</code>	Sets the threshold of FROM items beyond which GEQO is used.
<code>gin_fuzzy_search_limit</code>	Sets the maximum allowed result for exact search by GIN.
<code>gin_pending_list_limit</code>	(kB) Sets the maximum size of the pending list for GIN index.
<code>hash_mem_multiplier</code>	Multiple of <code>work_mem</code> to use for hash tables.
<code>hba_file</code>	Static. Sets the servers hba configuration file.
<code>hot_standby_feedback</code>	Allows feedback from a hot standby to the primary that will avoid query conflicts.
<code>ident_file</code>	Static. Sets the servers ident configuration file.
<code>idle_in_transaction_session_timeout</code>	(ms) Sets the maximum allowed duration of any idling transaction.
<code>joinCollapse_limit</code>	Sets the FROM-list size beyond which JOIN constructs are not flattened.

Parameter name	Description
<code>lc_messages</code>	Sets the language in which messages are displayed.
<code>listen_addresses</code>	Static. Sets the host name or IP address(es) to listen to.
<code>lo_compat_privileges</code>	Enables backward compatibility mode for privilege checks on large objects.
<code>log_connections</code>	Logs each successful connection.
<code>log_destination</code>	Sets the destination for server log output.
<code>log_directory</code>	Sets the destination directory for log files.
<code>log_disconnections</code>	Logs end of a session, including duration.
<code>log_duration</code>	Logs the duration of each completed SQL statement.
<code>log_error_verbosity</code>	Sets the verbosity of logged messages.
<code>log_executor_stats</code>	Writes executor performance statistics to the server log.
<code>log_file_mode</code>	Sets the file permissions for log files.
<code>log_filename</code>	Sets the file name pattern for log files.
<code>logging_collector</code>	Static. Start a subprocess to capture stderr output and/or csvlogs into log files.
<code>log_hostname</code>	Logs the host name in the connection logs.
<code>logical_decoding_work_mem</code>	(kB) This much memory can be used by each internal reorder buffer before spilling to disk.
<code>log_line_prefix</code>	Controls information prefixed to each log line.
<code>log_lock_waits</code>	Logs long lock waits.
<code>log_min_duration_sample</code>	(ms) Sets the minimum execution time above which a sample of statements will be logged. Sampling is determined by <code>log_statement_sample_rate</code> .
<code>log_min_duration_statement</code>	(ms) Sets the minimum execution time above which statements will be logged.
<code>log_min_error_statement</code>	Causes all statements generating error at or above this level to be logged.
<code>log_min_messages</code>	Sets the message levels that are logged.
<code>log_parameter_max_length</code>	(B) When logging statements, limit logged parameter values to first N bytes.
<code>log_parameter_max_length_on_error</code>	(B) When reporting an error, limit logged parameter values to first N bytes.

Parameter name	Description
<code>log_parser_stats</code>	Writes parser performance statistics to the server log.
<code>log_planner_stats</code>	Writes planner performance statistics to the server log.
<code>log_replication_commands</code>	Logs each replication command.
<code>log_rotation_age</code>	(min) Automatic log file rotation will occur after N minutes.
<code>log_rotation_size</code>	(kB) Automatic log file rotation will occur after N kilobytes.
<code>log_statement</code>	Sets the type of statements logged.
<code>log_statement_sample_rate</code>	Fraction of statements exceeding <code>log_min_duration_sample</code> to be logged.
<code>log_statement_stats</code>	Writes cumulative performance statistics to the server log.
<code>log_temp_files</code>	(kB) Log the use of temporary files larger than this number of kilobytes.
<code>log_timezone</code>	Sets the time zone to use in log messages.
<code>log_truncate_on_rotation</code>	Truncate existing log files of same name during log rotation.
<code>maintenance_io_concurrency</code>	A variant of <code>effective_ioConcurrency</code> that is used for maintenance work.
<code>maintenance_work_mem</code>	(kB) Sets the maximum memory to be used for maintenance operations.
<code>max_connections</code>	Static. Sets the maximum number of concurrent connections.
<code>max_files_per_process</code>	Static. Sets the maximum number of simultaneously open files for each server process.
<code>max_locks_per_transaction</code>	Static. Sets the maximum number of locks per transaction.
<code>max_parallel_maintenance_workers</code>	Sets the maximum number of parallel processes per maintenance operation.
<code>max_parallel_workers</code>	Sets the maximum number of parallel workers than can be active at one time.
<code>max_parallel_workers_per_gather</code>	Sets the maximum number of parallel processes per executor node.
<code>max_pred_locks_per_page</code>	Sets the maximum number of predicate-locked tuples per page.
<code>max_pred_locks_per_relation</code>	Sets the maximum number of predicate-locked pages and tuples per relation.

Parameter name	Description
<code>max_pred_locks_per_transaction</code>	Static. Sets the maximum number of predicate locks per transaction.
<code>max_slot_wal_keep_size</code>	(MB) Replication slots will be marked as failed, and segments released for deletion or recycling, if this much space is occupied by WAL on disk.
<code>max_stack_depth</code>	(kB) Sets the maximum stack depth, in kilobytes.
<code>max_standby_streaming_delay</code>	(ms) Sets the maximum delay before canceling queries when a hot standby server is processing streamed WAL data.
<code>max_worker_processes</code>	Static. Sets the maximum number of concurrent worker processes.
<code>min_parallel_index_scan_size</code>	(8kB) Sets the minimum amount of index data for a parallel scan.
<code>min_parallel_table_scan_size</code>	(8kB) Sets the minimum amount of table data for a parallel scan.
<code>old_snapshot_threshold</code>	Static. (min) Time before a snapshot is too old to read pages changed after the snapshot was taken.
<code>operator_precedence_warning</code>	Emit a warning for constructs that changed meaning since PostgreSQL 9.4.
<code>parallel_leader_participation</code>	Controls whether Gather and Gather Merge also run subplans.
<code>parallel_setup_cost</code>	Sets the planners estimate of the cost of starting up worker processes for parallel query.
<code>parallel_tuple_cost</code>	Sets the planners estimate of the cost of passing each tuple (row) from worker to master backend.
<code>pgaudit.log</code>	Specifies which classes of statements will be logged by session audit logging.
<code>pgaudit.log_catalog</code>	Specifies that session logging should be enabled in the case where all relations in a statement are in <code>pg_catalog</code> .
<code>pgaudit.log_level</code>	Specifies the log level that will be used for log entries.
<code>pgaudit.log_parameter</code>	Specifies that audit logging should include the parameters that were passed with the statement.
<code>pgaudit.log_relation</code>	Specifies whether session audit logging should create a separate log entry for each relation (TABLE, VIEW, etc.) referenced in a SELECT or DML statement.

Parameter name	Description
<code>pgaudit.log_statement_once</code>	Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.
<code>pgaudit.role</code>	Specifies the master role to use for object audit logging.
<code>pg_bigm.enable_recheck</code>	It specifies whether to perform Recheck which is an internal process of full text search.
<code>pg_bigm.gin_key_limit</code>	It specifies the maximum number of 2-grams of the search keyword to be used for full text search.
<code>pg_bigm.last_update</code>	Static. It reports the last updated date of the pg_bigm module.
<code>pg_bigm.similarity_limit</code>	It specifies the minimum threshold used by the similarity search.
<code>pg_hint_plan.debug_print</code>	Logs results of hint parsing.
<code>pg_hint_plan.enable_hint</code>	Force planner to use plans specified in the hint comment preceding to the query.
<code>pg_hint_plan.enable_hint_table</code>	Force planner to not get hint by using table lookups.
<code>pg_hint_plan.message_level</code>	Message level of debug messages.
<code>pg_hint_plan.parse_messages</code>	Message level of parse errors.
<code>pglogical.batch_inserts</code>	Static. Batch inserts if possible
<code>pglogical.conflict_log_level</code>	Sets log level used for logging resolved conflicts.
<code>pglogical.conflict_resolution</code>	Sets method used for conflict resolution for resolvable conflicts.
<code>pglogical.extra_connection_options</code>	connection options to add to all peer node connections
<code>pglogical.synchronous_commit</code>	Static. pglogical specific synchronous commit value
<code>pglogical.use_spi</code>	Static. Use SPI instead of low-level API for applying changes
<code>pg_similarity.block_is_normalized</code>	Sets if the result value is normalized or not.
<code>pg_similarity.block_threshold</code>	Sets the threshold used by the Block similarity function.
<code>pg_similarity.block_tokenizer</code>	Sets the tokenizer for Block similarity function.
<code>pg_similarity.cosine_is_normalized</code>	Sets if the result value is normalized or not.
<code>pg_similarity.cosine_threshold</code>	Sets the threshold used by the Cosine similarity function.

Parameter name	Description
pg_similarity.cosine_tokenizer	Sets the tokenizer for Cosine similarity function.
pg_similarity.dice_is_normalized	Sets if the result value is normalized or not.
pg_similarity.dice_threshold	Sets the threshold used by the Dice similarity measure.
pg_similarity.dice_tokenizer	Sets the tokenizer for Dice similarity measure.
pg_similarity.euclidean_is_normalized	Sets if the result value is normalized or not.
pg_similarity.euclidean_threshold	Sets the threshold used by the Euclidean similarity measure.
pg_similarity.euclidean_tokenizer	Sets the tokenizer for Euclidean similarity measure.
pg_similarity.hamming_is_normalized	Sets if the result value is normalized or not.
pg_similarity.hamming_threshold	Sets the threshold used by the Block similarity metric.
pg_similarity.jaccard_is_normalized	Sets if the result value is normalized or not.
pg_similarity.jaccard_threshold	Sets the threshold used by the Jaccard similarity measure.
pg_similarity.jaccard_tokenizer	Sets the tokenizer for Jaccard similarity measure.
pg_similarity.jaro_is_normalized	Sets if the result value is normalized or not.
pg_similarity.jaro_threshold	Sets the threshold used by the Jaro similarity measure.
pg_similarity.jarowinkler_is_normalized	Sets if the result value is normalized or not.
pg_similarity.jarowinkler_threshold	Sets the threshold used by the Jarowinkler similarity measure.
pg_similarity.levenshtein_is_normalized	Sets if the result value is normalized or not.
pg_similarity.levenshtein_threshold	Sets the threshold used by the Levenshtein similarity measure.
pg_similarity.matching_is_normalized	Sets if the result value is normalized or not.
pg_similarity.matching_threshold	Sets the threshold used by the Matching Coefficient similarity measure.
pg_similarity.matching_tokenizer	Sets the tokenizer for Matching Coefficient similarity measure.
pg_similarity.mongeelkan_is_normalized	Sets if the result value is normalized or not.
pg_similarity.mongeelkan_threshold	Sets the threshold used by the Monge-Elkan similarity measure.
pg_similarity.mongeelkan_tokenizer	Sets the tokenizer for Monge-Elkan similarity measure.

Parameter name	Description
<code>pg_similarity.nw_gap_penalty</code>	Sets the gap penalty used by the Needleman-Wunsch similarity measure.
<code>pg_similarity.nw_is_normalized</code>	Sets if the result value is normalized or not.
<code>pg_similarity.nw_threshold</code>	Sets the threshold used by the Needleman-Wunsch similarity measure.
<code>pg_similarity.overlap_is_normalized</code>	Sets if the result value is normalized or not.
<code>pg_similarity.overlap_threshold</code>	Sets the threshold used by the Overlap Coefficient similarity measure.
<code>pg_similarity.overlap_tokenizer</code>	Sets the tokenizer for Overlap Coefficientsimilarity measure.
<code>pg_similarity.qgram_is_normalized</code>	Sets if the result value is normalized or not.
<code>pg_similarity.qgram_threshold</code>	Sets the threshold used by the Q-Gram similarity measure.
<code>pg_similarity.qgram_tokenizer</code>	Sets the tokenizer for Q-Gram measure.
<code>pg_similarity.swg_is_normalized</code>	Sets if the result value is normalized or not.
<code>pg_similarity.swg_threshold</code>	Sets the threshold used by the Smith-Waterman-Gotoh similarity measure.
<code>pg_similarity.sw_is_normalized</code>	Sets if the result value is normalized or not.
<code>pg_similarity.sw_threshold</code>	Sets the threshold used by the Smith-Waterman similarity measure.
<code>pg_stat_statements.max</code>	Sets the maximum number of statements tracked by <code>pg_stat_statements</code> .
<code>pg_stat_statements.save</code>	Save <code>pg_stat_statements</code> statistics across server shutdowns.
<code>pg_stat_statements.track</code>	Selects which statements are tracked by <code>pg_stat_statements</code> .
<code>pg_stat_statements.track_planning</code>	Selects whether planning duration is tracked by <code>pg_stat_statements</code> .
<code>pg_stat_statements.track_utility</code>	Selects whether utility commands are tracked by <code>pg_stat_statements</code> .
<code>postgis.gdal_enabled_drivers</code>	Enable or disable GDAL drivers used with PostGIS in Postgres 9.3.5 and above.
<code>quote_all_identifiers</code>	When generating SQL fragments, quote all identifiers.
<code>random_page_cost</code>	Sets the planners estimate of the cost of a nonsequentially fetched disk page.
<code>rds.force_admin_logging_level</code>	See log messages for RDS admin user actions in customer databases.

Parameter name	Description
rds.log_retention_period	Amazon RDS will delete PostgreSQL log that are older than N minutes.
rds.pg_stat_ramdisk_size	Size of the stats ramdisk in MB. A nonzero value will setup the ramdisk.
rds.rds_superuser_reserved_connections	Sets the number of connection slots reserved for rds_superusers.
rds.superuser_variables	List of superuser-only variables for which we elevate rds_superuser modification statements.
restart_after_crash	Reinitialize server after backend crash.
row_security	Enable row security.
search_path	Sets the schema search order for names that are not schema-qualified.
seq_page_cost	Sets the planners estimate of the cost of a sequentially fetched disk page.
session_replication_role	Sets the sessions behavior for triggers and rewrite rules.
shared_buffers	(8kB) Sets the number of shared memory buffers used by the server.
shared_preload_libraries	Lists shared libraries to preload into server.
ssl_ca_file	Location of the SSL server authority file.
ssl_cert_file	Location of the SSL server certificate file.
ssl_key_file	Location of the SSL server private key file
standard_conforming_strings	Causes ... strings to treat backslashes literally.
statement_timeout	(ms) Sets the maximum allowed duration of any statement.
stats_temp_directory	Writes temporary statistics files to the specified directory.
superuser_reserved_connections	Static. Sets the number of connection slots reserved for superusers.
synchronize_seqscans	Enable synchronized sequential scans.
tcp_keepalives_count	Maximum number of TCP keepalive retransmits.
tcp_keepalives_idle	(s) Time between issuing TCP keepalives.
tcp_keepalives_interval	(s) Time between TCP keepalive retransmits.
temp_buffers	(8kB) Sets the maximum number of temporary buffers used by each session.

Parameter name	Description
<code>temp_file_limit</code>	Constrains the total amount disk space in kilobytes that a given PostgreSQL process can use for temporary files, excluding space used for explicit temporary tables
<code>temp_tablespaces</code>	Sets the tablespace(s) to use for temporary tables and sort files.
<code>track_activities</code>	Collects information about executing commands.
<code>track_activity_query_size</code>	Static. Sets the size reserved for <code>pg_stat_activity.current_query</code> , in bytes.
<code>track_counts</code>	Collects statistics on database activity.
<code>track_functions</code>	Collects function-level statistics on database activity.
<code>track_io_timing</code>	Collects timing statistics on database IO activity.
<code>transform_null_equals</code>	Treats <code>expr=NULL</code> as <code>expr IS NULL</code> .
<code>update_process_title</code>	Updates the process title to show the active SQL command.
<code>vacuum_cleanup_index_scale_factor</code>	Number of tuple inserts prior to index cleanup as a fraction of reltuples.
<code>wal_receiver_status_interval</code>	(s) Sets the maximum interval between WAL receiver status reports to the primary.
<code>work_mem</code>	(kB) Sets the maximum memory to be used for query workspaces.
<code>xmlbinary</code>	Sets how binary values are to be encoded in XML.
<code>xmloption</code>	Sets whether XML data in implicit parsing and serialization operations is to be considered as documents or content fragments.

## Amazon Aurora PostgreSQL wait events

The following are common wait events for Aurora PostgreSQL. To learn more about wait events and tuning your Aurora PostgreSQL DB cluster, see [Tuning with wait events for Aurora PostgreSQL \(p. 1152\)](#).

### **Activity:ArchiverMain**

The archiver process is waiting for activity.

### **Activity:AutoVacuumMain**

The autovacuum launcher process is waiting for activity.

### **Activity:BgWriterHibernate**

The background writer process is hibernating while waiting for activity.

### **Activity:BgWriterMain**

The background writer process is waiting for activity.

**Activity:CheckpointerMain**

The checkpointer process is waiting for activity.

**Activity:LogicalApplyMain**

The logical replication apply process is waiting for activity.

**Activity:LogicalLauncherMain**

The logical replication launcher process is waiting for activity.

**Activity:PgStatMain**

The statistics collector process is waiting for activity.

**Activity:RecoveryWalAll**

A process is waiting for the write-ahead log (WAL) from a stream at recovery.

**Activity:RecoveryWalStream**

The startup process is waiting for the write-ahead log (WAL) to arrive during streaming recovery.

**Activity:SysLoggerMain**

The syslogger process is waiting for activity.

**Activity:WalReceiverMain**

The write-ahead log (WAL) receiver process is waiting for activity.

**Activity:WalSenderMain**

The write-ahead log (WAL) sender process is waiting for activity.

**Activity:WalWriterMain**

The write-ahead log (WAL) writer process is waiting for activity.

**BufferPin:BufferPin**

A process is waiting to acquire an exclusive pin on a buffer.

**Client:GSSOpenServer**

A process is waiting to read data from the client while establishing a Generic Security Service Application Program Interface (GSSAPI) session.

**Client:ClientRead**

A backend process is waiting to receive data from a PostgreSQL client. For more information, see [Client:ClientRead \(p. 1158\)](#).

**Client:ClientWrite**

A backend process is waiting to send more data to a PostgreSQL client. For more information, see [Client:ClientWrite \(p. 1160\)](#).

**Client:LibPQWalReceiverConnect**

A process is waiting in the write-ahead log (WAL) receiver to establish connection to remote server.

**Client:LibPQWalReceiverReceive**

A process is waiting in the write-ahead log (WAL) receiver to receive data from remote server.

**Client:SSLOpenServer**

A process is waiting for Secure Sockets Layer (SSL) while attempting connection.

**Client:WalReceiverWaitStart**

A process is waiting for startup process to send initial data for streaming replication.

**Client:WalSenderWaitForWAL**

A process is waiting for the write-ahead log (WAL) to be flushed in the WAL sender process.

**Client:WalSenderWriteData**

A process is waiting for any activity when processing replies from the write-ahead log (WAL) receiver in the WAL sender process.

**CPU**

A backend process is active in or is waiting for CPU. For more information, see [CPU \(p. 1161\)](#).

**Extension:extension**

A backend process is waiting for a condition defined by an extension or module.

**IO:AuroraStorageLogAllocate**

A session is allocating metadata and preparing for a transaction log write.

**IO:BufFileRead**

When operations require more memory than the amount defined by working memory parameters, the engine creates temporary files on disk. This wait event occurs when operations read from the temporary files. For more information, see [IO:BufFileRead and IO:BufFileWrite \(p. 1166\)](#).

**IO:BufFileWrite**

When operations require more memory than the amount defined by working memory parameters, the engine creates temporary files on disk. This wait event occurs when operations write to the temporary files. For more information, see [IO:BufFileRead and IO:BufFileWrite \(p. 1166\)](#).

**IO:ControlFileRead**

A process is waiting for a read from the pg\_control file.

**IO:ControlFileSync**

A process is waiting for the pg\_control file to reach durable storage.

**IO:ControlFileSyncUpdate**

A process is waiting for an update to the pg\_control file to reach durable storage.

**IO:ControlFileWrite**

A process is waiting for a write to the pg\_control file.

**IO:ControlFileWriteUpdate**

A process is waiting for a write to update the pg\_control file.

**IO:CopyFileRead**

A process is waiting for a read during a file copy operation.

**IO:CopyFileWrite**

A process is waiting for a write during a file copy operation.

**IO:DataFileExtend**

A process is waiting for a relation data file to be extended.

**IO:DataFileFlush**

A process is waiting for a relation data file to reach durable storage.

**IO:DataFileImmediateSync**

A process is waiting for an immediate synchronization of a relation data file to durable storage.

**IO:DataFilePrefetch**

A process is waiting for an asynchronous prefetch from a relation data file.

**IO:DataFileSync**

A process is waiting for changes to a relation data file to reach durable storage.

**IO:DataFileRead**

A backend process tried to find a page in the shared buffers, didn't find it, and so read it from storage. For more information, see [IO:DataFileRead \(p. 1171\)](#).

**IO:DataFileTruncate**

A process is waiting for a relation data file to be truncated.

**IO:DataFileWrite**

A process is waiting for a write to a relation data file.

**IO:DSMFillZeroWrite**

A process is waiting to write zero bytes to a dynamic shared memory backing file.

**IO:LockFileAddToDataDirRead**

A process is waiting for a read while adding a line to the data directory lock file.

**IO:LockFileAddToDataDirSync**

A process is waiting for data to reach durable storage while adding a line to the data directory lock file.

**IO:LockFileAddToDataDirWrite**

A process is waiting for a write while adding a line to the data directory lock file.

**IO:LockFileCreateRead**

A process is waiting to read while creating the data directory lock file.

**IO:LockFileCreateSync**

A process is waiting for data to reach durable storage while creating the data directory lock file.

**IO:LockFileCreateWrite**

A process is waiting for a write while creating the data directory lock file.

**IO:LockFileReCheckDataDirRead**

A process is waiting for a read during recheck of the data directory lock file.

**IO:LogicalRewriteCheckpointSync**

A process is waiting for logical rewrite mappings to reach durable storage during a checkpoint.

**IO:LogicalRewriteMappingSync**

A process is waiting for mapping data to reach durable storage during a logical rewrite.

**IO:LogicalRewriteMappingWrite**

A process is waiting for a write of mapping data during a logical rewrite.

**IO:LogicalRewriteSync**

A process is waiting for logical rewrite mappings to reach durable storage.

**IO:LogicalRewriteTruncate**

A process is waiting for the truncation of mapping data during a logical rewrite.

**IO:LogicalRewriteWrite**

A process is waiting for a write of logical rewrite mappings.

**IO:RelationMapRead**

A process is waiting for a read of the relation map file.

**IO:RelationMapSync**

A process is waiting for the relation map file to reach durable storage.

**IO:RelationMapWrite**

A process is waiting for a write to the relation map file.

**IO:ReorderBufferRead**

A process is waiting for a read during reorder buffer management.

**IO:ReorderBufferWrite**

A process is waiting for a write during reorder buffer management.

**IO:ReorderLogicalMappingRead**

A process is waiting for a read of a logical mapping during reorder buffer management.

**IO:ReplicationSlotRead**

A process is waiting for a read from a replication slot control file.

**IO:ReplicationSlotRestoreSync**

A process is waiting for a replication slot control file to reach durable storage while restoring it to memory.

**IO:ReplicationSlotSync**

A process is waiting for a replication slot control file to reach durable storage.

**IO:ReplicationSlotWrite**

A process is waiting for a write to a replication slot control file.

**IO:SLRUFlushSync**

A process is waiting for segmented least-recently used (SLRU) data to reach durable storage during a checkpoint or database shutdown.

**IO:SLRURead**

A process is waiting for a read of a segmented least-recently used (SLRU) page.

**IO:SLRUSync**

A process is waiting for segmented least-recently used (SLRU) data to reach durable storage following a page write.

**IO:SLRUWrite**

A process is waiting for a write of a segmented least-recently used (SLRU) page.

**IO:SnapbuildRead**

A process is waiting for a read of a serialized historical catalog snapshot.

**IO:SnapbuildSync**

A process is waiting for a serialized historical catalog snapshot to reach durable storage.

**IO:SnapbuildWrite**

A process is waiting for a write of a serialized historical catalog snapshot.

**IO:TimelineHistoryFileSync**

A process is waiting for a timeline history file received through streaming replication to reach durable storage.

**IO:TimelineHistoryFileWrite**

A process is waiting for a write of a timeline history file received through streaming replication.

**IO:TimelineHistoryRead**

A process is waiting for a read of a timeline history file.

**IO:TimelineHistorySync**

A process is waiting for a newly created timeline history file to reach durable storage.

**IO:TimelineHistoryWrite**

A process is waiting for a write of a newly created timeline history file.

**IO:TwophaseFileRead**

A process is waiting for a read of a two phase state file.

**IO:TwophaseFileSync**

A process is waiting for a two phase state file to reach durable storage.

**IO:TwophaseFileWrite**

A process is waiting for a write of a two phase state file.

**IO:WALBootstrapSync**

A process is waiting for the write-ahead log (WAL) to reach durable storage during bootstrapping.

**IO:WALBootstrapWrite**

A process is waiting for a write of a write-ahead log (WAL) page during bootstrapping.

**IO:WALCopyRead**

A process is waiting for a read when creating a new write-ahead log (WAL) segment by copying an existing one.

**IO:WALCopySync**

A process is waiting for a new write-ahead log (WAL) segment created by copying an existing one to reach durable storage.

**IO:WALCopyWrite**

A process is waiting for a write when creating a new write-ahead log (WAL) segment by copying an existing one.

**IO:WALInitSync**

A process is waiting for a newly initialized write-ahead log (WAL) file to reach durable storage.

**IO:WALInitWrite**

A process is waiting for a write while initializing a new write-ahead log (WAL) file.

**IO:WALRead**

A process is waiting for a read from a write-ahead log (WAL) file.

**IO:WALSenderTimelineHistoryRead**

A process is waiting for a read from a timeline history file during a WAL sender timeline command.

**IO:WALSync**

A process is waiting for a write-ahead log (WAL) file to reach durable storage.

**IO:WALSyncMethodAssign**

A process is waiting for data to reach durable storage while assigning a new write-ahead log (WAL) sync method.

**IO:WALWrite**

A process is waiting for a write to a write-ahead log (WAL) file.

**IO:XactSync**

A backend process is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction. For more information, see [IO:XactSync \(p. 1177\)](#).

**IPC:BackupWaitWalArchive**

A process is waiting for write-ahead log (WAL) files required for a backup to be successfully archived.

**IPC:BgWorkerShutdown**

A process is waiting for a background worker to shut down.

**IPC:BgWorkerStartup**

A process is waiting for a background worker to start.

**IPC:BtreePage**

A process is waiting for the page number needed to continue a parallel B-tree scan to become available.

**IPC:CheckpointDone**

A process is waiting for a checkpoint to complete.

**IPC:CheckpointStart**

A process is waiting for a checkpoint to start.

**IPC:ClogGroupUpdate**

A process is waiting for the group leader to update the transaction status at a transaction's end.

**pc:damrecordtxack**

A backend process has generated a database activity streams event and is waiting for the event to become durable. For more information, see [ipc:damrecordtxack \(p. 1179\)](#).

**IPC:ExecuteGather**

A process is waiting for activity from a child process while executing a Gather plan node.

**IPC:Hash/Batch/Allocating**

A process is waiting for an elected parallel hash participant to allocate a hash table.

**IPC:Hash/Batch/Electing**

A process is electing a parallel hash participant to allocate a hash table.

**IPC:Hash/Batch>Loading**

A process is waiting for other parallel hash participants to finish loading a hash table.

### **IPC:Hash/Build/Allocating**

A process is waiting for an elected parallel hash participant to allocate the initial hash table.

### **IPC:Hash/Build/Electing**

A process is electing a parallel hash participant to allocate the initial hash table.

### **IPC:Hash/Build/HashingInner**

A process is waiting for other parallel hash participants to finish hashing the inner relation.

### **IPC:Hash/Build/HashingOuter**

A process is waiting for other parallel hash participants to finish partitioning the outer relation.

### **IPC:Hash/GrowBatches/Allocating**

A process is waiting for an elected parallel hash participant to allocate more batches.

### **IPC:Hash/GrowBatches/Deciding**

A process is electing a parallel hash participant to decide on future batch growth.

### **IPC:Hash/GrowBatches/Electing**

A process is electing a parallel hash participant to allocate more batches.

### **IPC:Hash/GrowBatches/Finishing**

A process is waiting for an elected parallel hash participant to decide on future batch growth.

### **IPC:Hash/GrowBatches/Repartitioning**

A process is waiting for other parallel hash participants to finishing repartitioning.

### **IPC:Hash/GrowBuckets/Allocating**

A process is waiting for an elected parallel hash participant to finish allocating more buckets.

### **IPC:Hash/GrowBuckets/Electing**

A process is electing a parallel hash participant to allocate more buckets.

### **IPC:Hash/GrowBuckets/Reinserting**

A process is waiting for other parallel hash participants to finish inserting tuples into new buckets.

### **IPC:HashBatchAllocate**

A process is waiting for an elected parallel hash participant to allocate a hash table.

### **IPC:HashBatchElect**

A process is waiting to elect a parallel hash participant to allocate a hash table.

### **IPC:HashBatchLoad**

A process is waiting for other parallel hash participants to finish loading a hash table.

### **IPC:HashBuildAllocate**

A process is waiting for an elected parallel hash participant to allocate the initial hash table.

### **IPC:HashBuildElect**

A process is waiting to elect a parallel hash participant to allocate the initial hash table.

### **IPC:HashBuildHashInner**

A process is waiting for other parallel hash participants to finish hashing the inner relation.

**IPC:'HashBuildHashOuter**

A process is waiting for other parallel hash participants to finish partitioning the outer relation.

**IPC:HashGrowBatchesAllocate**

A process is waiting for an elected parallel hash participant to allocate more batches.

**IPC:'HashGrowBatchesDecide**

A process is waiting to elect a parallel hash participant to decide on future batch growth.

**IPC:HashGrowBatchesElect**

A process is waiting to elect a parallel hash participant to allocate more batches.

**IPC:HashGrowBatchesFinish**

A process is waiting for an elected parallel hash participant to decide on future batch growth.

**IPC:HashGrowBatchesRepartition**

A process is waiting for other parallel hash participants to finish repartitioning.

**IPC:HashGrowBucketsAllocate**

A process is waiting for an elected parallel hash participant to finish allocating more buckets.

**IPC:HashGrowBucketsElect**

A process is waiting to elect a parallel hash participant to allocate more buckets.

**IPC:HashGrowBucketsReinsert**

A process is waiting for other parallel hash participants to finish inserting tuples into new buckets.

**IPC:LogicalSyncData**

A process is waiting for a logical replication remote server to send data for initial table synchronization.

**IPC:LogicalSyncStateChange**

A process is waiting for a logical replication remote server to change state.

**IPC:MessageQueueInternal**

A process is waiting for another process to be attached to a shared message queue.

**IPC:MessageQueuePutMessage**

A process is waiting to write a protocol message to a shared message queue.

**IPC:MessageQueueReceive**

A process is waiting to receive bytes from a shared message queue.

**IPC:MessageQueueSend**

A process is waiting to send bytes to a shared message queue.

**IPC:ParallelBitmapScan**

A process is waiting for a parallel bitmap scan to become initialized.

**IPC:ParallelCreateIndexScan**

A process is waiting for parallel CREATE INDEX workers to finish a heap scan.

**IPC:ParallelFinish**

A process is waiting for parallel workers to finish computing.

**IPC:ProcArrayGroupUpdate**

A process is waiting for the group leader to clear the transaction ID at the end of a parallel operation.

**IPC:ProcSignalBarrier**

A process is waiting for a barrier event to be processed by all backends.

**IPC:Promote**

A process is waiting for standby promotion.

**IPC:RecoveryConflictSnapshot**

A process is waiting for recovery conflict resolution for a vacuum cleanup.

**IPC:RecoveryConflictTablespace**

A process is waiting for recovery conflict resolution for dropping a tablespace.

**IPC:RecoveryPause**

A process is waiting for recovery to be resumed.

**IPC:ReplicationOriginDrop**

A process is waiting for a replication origin to become inactive so it can be dropped.

**IPC:ReplicationSlotDrop**

A process is waiting for a replication slot to become inactive so it can be dropped.

**IPC:SafeSnapshot**

A process is waiting to obtain a valid snapshot for a READ ONLY DEFERRABLE transaction.

**IPC:SyncRep**

A process is waiting for confirmation from a remote server during synchronous replication.

**IPC:XactGroupUpdate**

A process is waiting for the group leader to update the transaction status at the end of a parallel operation.

**Lock:advisory**

A backend process requested an advisory lock and is waiting for it. For more information, see [Lock:advisory \(p. 1180\)](#).

**Lock:extend**

A backend process is waiting for a lock to be released so that it can extend a relation. This lock is needed because only one backend process can extend a relation at a time. For more information, see [Lock:extend \(p. 1182\)](#).

**Lock:frozenid**

A process is waiting to update pg\_database.datfrozenxid and pg\_database.datminmxid.

**Lock:object**

A process is waiting to get a lock on a nonrelation database object.

**Lock:page**

A process is waiting to get a lock on a page of a relation.

**Lock:Relation**

A backend process is waiting to acquire a lock on a relation that is locked by another transaction. For more information, see [Lock:Relation \(p. 1184\)](#).

**Lock:spectoken**

A process is waiting to get a speculative insertion lock.

**Lock:speculative token**

A process is waiting to acquire a speculative insertion lock.

**Lock:transactionid**

A transaction is waiting for a row-level lock. For more information, see [Lock:transactionid \(p. 1187\)](#).

**Lock:tuple**

A backend process is waiting to acquire a lock on a tuple while another backend process holds a conflicting lock on the same tuple. For more information, see [Lock:tuple \(p. 1189\)](#).

**Lock:userlock**

A process is waiting to get a user lock.

**Lock:virtualxid**

A process is waiting to get a virtual transaction ID lock.

**Lwlock:AddinShmemInit**

A process is waiting to manage an extension's space allocation in shared memory.

**Lwlock:AddinShmemInitLock**

A process is waiting to manage space allocation in shared memory.

**Lwlock:async**

A process is waiting for I/O on an async (notify) buffer.

**Lwlock:AsyncCtlLock**

A process is waiting to read or update a shared notification state.

**Lwlock:AsyncQueueLock**

A process is waiting to read or update notification messages.

**Lwlock:AutoFile**

A process is waiting to update the `postgresql.auto.conf` file.

**Lwlock:AutoFileLock**

A process is waiting to update the `postgresql.auto.conf` file.

**Lwlock:Autovacuum**

A process is waiting to read or update the current state of autovacuum workers.

**Lwlock:AutovacuumLock**

An autovacuum worker or launcher is waiting to update or read the current state of autovacuum workers.

**Lwlock:AutovacuumSchedule**

A process is waiting to ensure that a table selected for autovacuum still needs vacuuming.

**Lwlock:AutovacuumScheduleLock**

A process is waiting to ensure that the table it has selected for a vacuum still needs vacuuming.

**Lwlock:BackendRandomLock**

A process is waiting to generate a random number.

### **Lwlock:BackgroundWorker**

A process is waiting to read or update background worker state.

### **Lwlock:BackgroundWorkerLock**

A process is waiting to read or update the background worker state.

### **Lwlock:BtreeVacuum**

A process is waiting to read or update vacuum-related information for a B-tree index.

### **Lwlock:BtreeVacuumLock**

A process is waiting to read or update vacuum-related information for a B-tree index.

### **LWLock:buffer\_content**

A backend process is waiting to acquire a lightweight lock on the contents of a shared memory buffer. For more information, see [Lwlock:buffer\\_content \(BufferContent\) \(p. 1192\)](#).

### **LWLock:buffer\_mapping**

A backend process is waiting to associate a data block with a buffer in the shared buffer pool. For more information, see [LWLock:buffer\\_mapping \(p. 1193\)](#).

### **LWLock:BufferIO**

A backend process wants to read a page into shared memory. The process is waiting for other processes to finish their I/O for the page. For more information, see [LWLock:BufferIO \(p. 1195\)](#).

### **Lwlock:Checkpoint**

A process is waiting to begin a checkpoint.

### **Lwlock:CheckpointLock**

A process is waiting to perform checkpoint.

### **Lwlock:CheckpointerComm**

A process is waiting to manage `fsync` requests.

### **Lwlock:CheckpointerCommLock**

A process is waiting to manage `fsync` requests.

### **Lwlock:clog**

A process is waiting for I/O on a clog (transaction status) buffer.

### **Lwlock:CLogControlLock**

A process is waiting to read or update transaction status.

### **Lwlock:CLogTruncationLock**

A process is waiting to run `txid_status` or update the oldest transaction ID available to it.

### **Lwlock:commit\_timestamp**

A process is waiting for I/O on a commit timestamp buffer.

### **Lwlock:CommitTs**

A process is waiting to read or update the last value set for a transaction commit timestamp.

### **Lwlock:CommitTsBuffer**

A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a commit timestamp.

**Lwlock:CommitTsControlLock**

A process is waiting to read or update transaction commit timestamps.

**Lwlock:CommitTsLock**

A process is waiting to read or update the last value set for the transaction timestamp.

**Lwlock:CommitTsSLRU**

A process is waiting to access the segmented least-recently used (SLRU) cache for a commit timestamp.

**Lwlock:ControlFile**

A process is waiting to read or update the `pg_control` file or create a new write-ahead log (WAL) file.

**Lwlock:ControlFileLock**

A process is waiting to read or update the control file or creation of a new write-ahead log (WAL) file.

**Lwlock:DynamicSharedMemoryControl**

A process is waiting to read or update dynamic shared memory allocation information.

**Lwlock:DynamicSharedMemoryControlLock**

A process is waiting to read or update the dynamic shared memory state.

**LWLock:lock\_manager**

A backend process is waiting to add or examine locks for backend processes. Or it's waiting to join or exit a locking group that is used by parallel query. For more information, see

[LWLock:lock\\_manager \(p. 1196\)](#).

**Lwlock:LockFastPath**

A process is waiting to read or update a process's fast-path lock information.

**Lwlock:LogicalRepWorker**

A process is waiting to read or update the state of logical replication workers.

**Lwlock:LogicalRepWorkerLock**

A process is waiting for an action on a logical replication worker to finish.

**Lwlock:multipxact\_member**

A process is waiting for I/O on a multipxact\_member buffer.

**Lwlock:multipxact\_offset**

A process is waiting for I/O on a multipxact offset buffer.

**Lwlock:MultiXactGen**

A process is waiting to read or update shared multixact state.

**Lwlock:MultiXactGenLock**

A process is waiting to read or update a shared multixact state.

**Lwlock:MultiXactMemberBuffer**

A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a multixact member.

**Lwlock:MultiXactMemberControlLock**

A process is waiting to read or update multixact member mappings.

**Lwlock:MultiXactMemberSLRU**

A process is waiting to access the segmented least-recently used (SLRU) cache for a multixact member.

**Lwlock:MultiXactOffsetBuffer**

A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a multixact offset.

**Lwlock:MultiXactOffsetControlLock**

A process is waiting to read or update multixact offset mappings.

**Lwlock:MultiXactOffsetSLRU**

A process is waiting to access the segmented least-recently used (SLRU) cache for a multixact offset.

**Lwlock:MultiXactTruncation**

A process is waiting to read or truncate multixact information.

**Lwlock:MultiXactTruncationLock**

A process is waiting to read or truncate multixact information.

**Lwlock:NotifyBuffer**

A process is waiting for I/O on the segmented least-recently used (SLRU) buffer for a NOTIFY message.

**Lwlock:NotifyQueue**

A process is waiting to read or update NOTIFY messages.

**Lwlock:NotifyQueueTail**

A process is waiting to update a limit on NOTIFY message storage.

**Lwlock:NotifyQueueTailLock**

A process is waiting to update limit on notification message storage.

**Lwlock:NotifySLRU**

A process is waiting to access the segmented least-recently used (SLRU) cache for a NOTIFY message.

**Lwlock:OidGen**

A process is waiting to allocate a new object ID (OID).

**Lwlock:OidGenLock**

A process is waiting to allocate or assign an object ID (OID).

**Lwlock:oldserxid**

A process is waiting for I/O on an oldserxid buffer.

**Lwlock:OldSerXidLock**

A process is waiting to read or record conflicting serializable transactions.

**Lwlock:OldSnapshotTimeMap**

A process is waiting to read or update old snapshot control information.

**Lwlock:OldSnapshotTimeMapLock**

A process is waiting to read or update old snapshot control information.

**Lwlock:parallel\_append**

A process is waiting to choose the next subplan during parallel append plan execution.

**Lwlock:parallel\_hash\_join**

A process is waiting to allocate or exchange a chunk of memory or update counters during a parallel hash plan execution.

**Lwlock:parallel\_query\_dsa**

A process is waiting for a lock on dynamic shared memory allocation for a parallel query.

**Lwlock:ParallelAppend**

A process is waiting to choose the next subplan during parallel append plan execution.

**Lwlock:ParallelHashJoin**

A process is waiting to synchronize workers during plan execution for a parallel hash join.

**Lwlock:ParallelQueryDSA**

A process is waiting for dynamic shared memory allocation for a parallel query.

**Lwlock:PerSessionDSA**

A process is waiting for dynamic shared memory allocation for a parallel query.

**Lwlock:PerSessionRecordType**

A process is waiting to access a parallel query's information about composite types.

**Lwlock:PerSessionRecordTypmod**

A process is waiting to access a parallel query's information about type modifiers that identify anonymous record types.

**Lwlock:PerXactPredicateList**

A process is waiting to access the list of predicate locks held by the current serializable transaction during a parallel query.

**Lwlock:predicate\_lock\_manager**

A process is waiting to add or examine predicate lock information.

**Lwlock:PredicateLockManager**

A process is waiting to access predicate lock information used by serializable transactions.

**Lwlock:proc**

A process is waiting to read or update the fast-path lock information.

**Lwlock:ProcArray**

A process is waiting to access the shared per-process data structures (typically, to get a snapshot or report a session's transaction ID).

**Lwlock:ProcArrayLock**

A process is waiting to get a snapshot or clearing a transaction Id at a transaction's end.

**Lwlock:RelationMapping**

A process is waiting to read or update a pg\_filenode.map file (used to track the file-node assignments of certain system catalogs).

**Lwlock:RelationMappingLock**

A process is waiting to update the relation map file used to store catalog-to-file-node mapping.

**Lwlock:RelCacheInit**

A process is waiting to read or update a `pg_internal.init` file (a relation cache initialization file).

**Lwlock:RelCacheInitLock**

A process is waiting to read or write a relation cache initialization file.

**Lwlock:replication\_origin**

A process is waiting to read or update the replication progress.

**Lwlock:replication\_slot\_io**

A process is waiting for I/O on a replication slot.

**Lwlock:ReplicationOrigin**

A process is waiting to create, drop, or use a replication origin.

**Lwlock:ReplicationOriginLock**

A process is waiting to set up, drop, or use a replication origin.

**Lwlock:ReplicationOriginState**

A process is waiting to read or update the progress of one replication origin.

**Lwlock:ReplicationSlotAllocation**

A process is waiting to allocate or free a replication slot.

**Lwlock:ReplicationSlotAllocationLock**

A process is waiting to allocate or free a replication slot.

**Lwlock:ReplicationSlotControl**

A process is waiting to read or update a replication slot state.

**Lwlock:ReplicationSlotControlLock**

A process is waiting to read or update the replication slot state.

**Lwlock:ReplicationSlotIO**

A process is waiting for I/O on a replication slot.

**Lwlock:SerialBuffer**

A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a serializable transaction conflict.

**Lwlock:SerializableFinishedList**

A process is waiting to access the list of finished serializable transactions.

**Lwlock:SerializableFinishedListLock**

A process is waiting to access the list of finished serializable transactions.

**Lwlock:SerializablePredicateList**

A process is waiting to access the list of predicate locks held by serializable transactions.

**Lwlock:SerializablePredicateLockListLock**

A process is waiting to perform an operation on a list of locks held by serializable transactions.

**Lwlock:SerializableXactHash**

A process is waiting to read or update information about serializable transactions.

**Lwlock:SerializableXactHashLock**

A process is waiting to retrieve or store information about serializable transactions.

**Lwlock:SerialSLRU**

A process is waiting to access the segmented least-recently used (SLRU) cache for a serializable transaction conflict.

**Lwlock:SharedTidBitmap**

A process is waiting to access a shared tuple identifier (TID) bitmap during a parallel bitmap index scan.

**Lwlock:SharedTupleStore**

A process is waiting to access a shared tuple store during a parallel query.

**Lwlock:ShmemIndex**

A process is waiting to find or allocate space in shared memory.

**Lwlock:ShmemIndexLock**

A process is waiting to find or allocate space in shared memory.

**Lwlock:SInvalRead**

A process is waiting to retrieve messages from the shared catalog invalidation queue.

**Lwlock:SInvalReadLock**

A process is waiting to retrieve or remove messages from a shared invalidation queue.

**Lwlock:SInvalWrite**

A process is waiting to add a message to the shared catalog invalidation queue.

**Lwlock:SInvalWriteLock**

A process is waiting to add a message in a shared invalidation queue.

**Lwlock:subtrans**

A process is waiting for I/O on a subtransaction buffer.

**Lwlock:SubtransBuffer**

A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a subtransaction.

**Lwlock:SubtransControlLock**

A process is waiting to read or update subtransaction information.

**Lwlock:SubtransSLRU**

A process is waiting to access the segmented least-recently used (SLRU) cache for a subtransaction.

**Lwlock:SyncRep**

A process is waiting to read or update information about the state of synchronous replication.

**Lwlock:SyncRepLock**

A process is waiting to read or update information about synchronous replicas.

**Lwlock:SyncScan**

A process is waiting to select the starting location of a synchronized table scan.

**Lwlock:SyncScanLock**

A process is waiting to get the start location of a scan on a table for synchronized scans.

**Lwlock:TablespaceCreate**

A process is waiting to create or drop a tablespace.

**Lwlock:TablespaceCreateLock**

A process is waiting to create or drop the tablespace.

**Lwlock:tbm**

A process is waiting for a shared iterator lock on a tree bitmap (TBM).

**Lwlock:TwoPhaseState**

A process is waiting to read or update the state of prepared transactions.

**Lwlock:TwoPhaseStateLock**

A process is waiting to read or update the state of prepared transactions.

**Lwlock:wal\_insert**

A process is waiting to insert the write-ahead log (WAL) into a memory buffer.

**Lwlock:WALBufMapping**

A process is waiting to replace a page in write-ahead log (WAL) buffers.

**Lwlock:WALBufMappingLock**

A process is waiting to replace a page in write-ahead log (WAL) buffers.

**Lwlock:WALInsert**

A process is waiting to insert write-ahead log (WAL) data into a memory buffer.

**Lwlock:WALWrite**

A process is waiting for write-ahead log (WAL) buffers to be written to disk.

**Lwlock:WALWriteLock**

A process is waiting for write-ahead log (WAL) buffers to be written to disk.

**Lwlock:WrapLimitsVacuum**

A process is waiting to update limits on transaction ID and multixact consumption.

**Lwlock:WrapLimitsVacuumLock**

A process is waiting to update limits on transaction ID and multixact consumption.

**Lwlock:XactBuffer**

A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a transaction status.

**Lwlock:XactSLRU**

A process is waiting to access the segmented least-recently used (SLRU) cache for a transaction status.

**Lwlock:XactTruncation**

A process is waiting to run pg\_xact\_status or update the oldest transaction ID available to it.

**Lwlock:XidGen**

A process is waiting to allocate a new transaction ID.

**Lwlock:XidGenLock**

A process is waiting to allocate or assign a transaction ID.

#### **Timeout:BaseBackupThrottle**

A process is waiting during base backup when throttling activity.

#### **Timeout:PgSleep**

A backend process has called the pg\_sleep function and is waiting for the sleep timeout to expire.

For more information, see [Timeout:PgSleep \(p. 1199\)](#).

#### **Timeout:RecoveryApplyDelay**

A process is waiting to apply write-ahead log (WAL) during recovery because of a delay setting.

#### **Timeout:RecoveryRetrieveRetryInterval**

A process is waiting during recovery when write-ahead log (WAL) data is not available from any source (pg\_wal, archive, or stream).

#### **Timeout:VacuumDelay**

A process is waiting in a cost-based vacuum delay point.

For a complete list of PostgreSQL wait events, see [The Statistics Collector > Wait Event tables](#) in the PostgreSQL documentation.

## Amazon Aurora PostgreSQL updates

Following, you can find information about Amazon Aurora PostgreSQL engine version releases and updates. You can also find information about how to upgrade your Aurora PostgreSQL engine. For more information about Aurora releases in general, see [Amazon Aurora versions \(p. 5\)](#).

### Topics

- [Identifying versions of Amazon Aurora PostgreSQL \(p. 1413\)](#)
- [Amazon Aurora PostgreSQL releases and engine versions \(p. 1414\)](#)
- [Extension versions for Amazon Aurora PostgreSQL \(p. 1415\)](#)
- [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL \(p. 1415\)](#)
- [Aurora PostgreSQL long-term support \(LTS\) releases \(p. 1429\)](#)

## Identifying versions of Amazon Aurora PostgreSQL

Amazon Aurora includes certain features that are general to Aurora and available to all Aurora DB clusters. Aurora includes other features that are specific to a particular database engine that Aurora supports. These features are available only to those Aurora DB clusters that use that database engine, such as Aurora PostgreSQL.

An Aurora database release typically has two version numbers, the database engine version number and the Aurora version number. If an Aurora PostgreSQL release has an Aurora version number, it's included after the engine version number in the [Amazon Aurora PostgreSQL releases and engine versions \(p. 1414\)](#) listing.

### Aurora version number

Aurora version numbers use the `major.minor.patch` naming scheme. An Aurora patch version includes important bug fixes added to a minor version after its release. To learn more about Amazon Aurora major, minor, and patch releases, see [Amazon Aurora major versions \(p. 6\)](#), [Amazon Aurora minor versions \(p. 7\)](#), and [Amazon Aurora patch versions \(p. 7\)](#).

You can find out the Aurora version number of your Aurora PostgreSQL DB instance with the following SQL query:

```
pgres=> SELECT aurora_version();
```

Starting with the release of PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers align more closely to the PostgreSQL engine version. For example, querying an Aurora PostgreSQL 13.3 DB cluster returns the following:

```
aurora_version
-----
13.3.1
(1 row)
```

Prior releases, such as Aurora PostgreSQL 10.14 DB cluster, return version numbers similar to the following:

```
aurora_version
-----
2.7.3
(1 row)
```

## PostgreSQL engine version numbers

Starting with PostgreSQL 10, PostgreSQL database engine versions use a *major.minor* numbering scheme for all releases. Some examples include PostgreSQL 10.18, PostgreSQL 12.7, and PostgreSQL 13.3.

Releases prior to PostgreSQL 10 use a *major.major.minor* numbering scheme in which the first two digits make up the major version number and a third digit denotes a minor version. For example, PostgreSQL 9.6 is a major version, with minor versions 9.6.21 or 9.6.22 indicated by the third digit.

### Note

The PostgreSQL engine version 9.6 is no longer supported. To upgrade, see [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL \(p. 1415\)](#).

You can find out the PostgreSQL database engine version number with the following SQL query:

```
pgres=> SELECT version();
```

For an Aurora PostgreSQL 13.3 DB cluster, the results are as follows:

```
version
-----
PostgreSQL 13.3 on x86_64-pc-linux-gnu, compiled by x86_64-pc-linux-gnu-gcc (GCC) 7.4.0,
64-bit
(1 row)
```

## Amazon Aurora PostgreSQL releases and engine versions

Amazon Aurora PostgreSQL-Compatible Edition releases update regularly. Updates are applied to Aurora PostgreSQL DB clusters during system maintenance windows. The timing when updates are applied depends on the AWS Region and maintenance window setting for the DB cluster, and also the type of

update. Many of the listed releases include both a PostgreSQL version number and an Amazon Aurora version number. However, starting with the release of PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers aren't used. To determine the version numbers of your Aurora PostgreSQL database, see [Identifying versions of Amazon Aurora PostgreSQL \(p. 1413\)](#).

For information about extensions and modules, see [Extension versions for Amazon Aurora PostgreSQL \(p. 1415\)](#).

For more information about Amazon Aurora available releases, policies, and timelines, see [How long Amazon Aurora major versions remain available \(p. 8\)](#). For more information about support and other policies for Amazon Aurora see [Amazon RDS FAQs](#).

To determine which Aurora PostgreSQL DB engine versions are available in an AWS Region, use the `describe-db-engine-versions` AWS CLI command. For example:

```
aws rds describe-db-engine-versions --engine aurora-postgresql --query '*[].[EngineVersion]' --output text --region aws-region
```

For a list of AWS Regions, see [Aurora PostgreSQL Region availability \(p. 14\)](#).

For details about the PostgreSQL versions that are available on Aurora PostgreSQL, see the [Release Notes for Aurora PostgreSQL](#).

## Extension versions for Amazon Aurora PostgreSQL

You can install and configure various PostgreSQL extensions for use with Aurora PostgreSQL DB clusters. For example, you can use the PostgreSQL `pg_partman` extension to automate the creation and maintenance of table partitions. To learn more about this and other extensions available for Aurora PostgreSQL, see [Working with extensions and foreign data wrappers \(p. 1318\)](#).

For details about the PostgreSQL extensions that are supported on Aurora PostgreSQL, see [Extension versions for Amazon Aurora PostgreSQL](#) in [Release Notes for Aurora PostgreSQL](#).

## Upgrading the PostgreSQL DB engine for Aurora PostgreSQL

Amazon Aurora makes new versions of the PostgreSQL database engine available in AWS Regions only after extensive testing. You can upgrade your Aurora PostgreSQL DB clusters to the new version when it's available in your Region.

Depending on the version of Aurora PostgreSQL that your DB cluster is currently running, an upgrade to the new release is either a minor upgrade or a major upgrade. For example, upgrading an Aurora PostgreSQL 11.15 DB cluster to Aurora PostgreSQL 13.6 is a *major version upgrade*. Upgrading an Aurora PostgreSQL 13.3 DB cluster to Aurora PostgreSQL 13.7 is a *minor version upgrade*. In the following topics, you can find information about how to perform both types of upgrades.

### Contents

- [Overview of the Aurora PostgreSQL upgrade processes \(p. 1416\)](#)
- [How to perform a major version upgrade \(p. 1417\)](#)
  - [Getting a list of available versions in your AWS Region \(p. 1418\)](#)

- Upgrading the Aurora PostgreSQL engine to a new minor version ([p. 1427](#))
- Upgrading PostgreSQL extensions ([p. 1428](#))

## Overview of the Aurora PostgreSQL upgrade processes

The differences between major and minor version upgrades are as follows:

### Minor version upgrades and patches

Minor version upgrades and patches include only those changes that are backward-compatible with existing applications. Minor version upgrades and patches become available to you only after Aurora PostgreSQL tests and approves them.

Minor version upgrades can be applied for you automatically by Aurora. When you create a new Aurora PostgreSQL DB cluster, the **Enable minor version upgrade** option is preselected. Unless you turn off this option, minor version upgrades are applied automatically during your scheduled maintenance window. For more information about the automatic minor version upgrade (AMVU) option and how to modify your Aurora DB cluster to use it, see [Automatic minor version upgrades for Aurora DB clusters \(p. 327\)](#).

If the automatic minor version upgrade option isn't set for your Aurora PostgreSQL DB cluster, your Aurora PostgreSQL isn't automatically upgraded to the new minor version. Instead, when a new minor version is released in your AWS Region and your Aurora PostgreSQL DB cluster is running an older minor version, Aurora prompts you to upgrade. It does so by adding a recommendation to the maintenance tasks for your cluster.

Patches aren't considered an upgrade, and they aren't applied automatically. Aurora PostgreSQL prompts you to apply any patches by adding a recommendation to maintenance tasks for your Aurora PostgreSQL DB cluster. For more information, see [How to perform minor version upgrades and apply patches \(p. 1425\)](#).

#### Note

Patches that resolve security or other critical issues are also added as maintenance tasks.

However, these patches are required. Make sure to apply security patches to your Aurora PostgreSQL DB cluster when they become available in your pending maintenance tasks.

The upgrade process involves the possibility of brief outages as each instance in the cluster is upgraded to the new version. However, after Aurora PostgreSQL versions 14.3.1, 13.7.1, 12.11.1, 11.16.1, and 10.21.1 and other higher releases of these minor versions, the upgrade process uses the zero-downtime patching (ZDP) feature. This feature minimizes outages, and in most cases completely eliminates them. For more information, see [Minor release upgrades and zero-downtime patching \(p. 1426\)](#).

#### Note

ZDP isn't supported for Aurora PostgreSQL DB clusters that are configured as Aurora Serverless v2, Aurora Serverless v1, Aurora global databases, or Babelfish.

### Major version upgrades

Unlike for minor version upgrades and patches, Aurora PostgreSQL doesn't have an automatic major version upgrade option. New major PostgreSQL versions might contain database changes that aren't backward-compatible with existing applications. The new functionality can cause your existing applications to stop working correctly.

To prevent any issues, we strongly recommend that you follow the process outlined in [Before upgrading your production DB cluster to a new major version \(p. 1419\)](#) before upgrading the DB instances in your Aurora PostgreSQL DB clusters. First ensure that your applications can run on the

new version by following that procedure. Then you can manually upgrade your Aurora PostgreSQL DB cluster to the new version.

The upgrade process involves the possibility of brief outages as each instance in the cluster is upgraded to the new version. The preliminary planning process also takes time. We recommend that you always perform upgrade tasks during your cluster's maintenance window or when operations are minimal. For more information, see [How to perform a major version upgrade \(p. 1417\)](#).

**Note**

Both minor version upgrades and major version upgrades might involve brief outages. For that reason, we recommend strongly that you perform or schedule upgrades during your maintenance window or during other periods of low utilization.

## How to perform a major version upgrade

Major version upgrades might contain database changes that are not backward-compatible with previous versions of the database. New functionality in a new version can cause your existing applications to stop working correctly. To avoid issues, Amazon Aurora doesn't apply major version upgrades automatically. Rather, we recommend that you carefully plan for a major version upgrade by following these steps:

1. Choose the major version that you want from the list of available targets from those listed for your version in the table. You can get a precise list of versions available in your AWS Region for your current version by using the AWS CLI. For details, see [Getting a list of available versions in your AWS Region \(p. 1418\)](#).
2. Verify that your applications work as expected on a trial deployment of the new version. For information about the complete process, see [Before upgrading your production DB cluster to a new major version \(p. 1419\)](#).
3. After verifying that your applications work as expected on the trial deployment, you can upgrade your cluster. For details, see [Upgrading the Aurora PostgreSQL engine to a new major version \(p. 1422\)](#).

**Note**

Currently, you can't upgrade an Aurora PostgreSQL DB cluster running Babelfish to a new major version.

In the table, you can find the major version upgrades that are available for various Aurora PostgreSQL DB versions.

Current source version	Major upgrade targets											
13.7	14.3											
13.6	14.3	13.7										
13.5	14.3	13.7	13.6									
13.4	14.3	13.7	13.6	13.5								
13.3	14.3	13.7	13.6	13.5	13.4							
12.11	14.3	13.7										
12.10	13.7	13.6	12.11									
12.9	13.7	13.6	13.5	12.11	12.10							

<b>Current source version</b>	<b>Major upgrade targets</b>													
12.8	13.7	13.6	13.5	13.4	12.11	12.10	12.9							
12.7	13.7	13.6	13.5	13.4	13.3	12.11	12.10	12.9	12.8					
12.6	13.7	13.6	13.5	13.4	13.3	12.11	12.10	12.9	12.8	12.7				
12.4	13.7	13.6	13.5	13.4	13.3	12.11	12.10	12.9	12.8	12.7	12.6			
11.16	14.3	13.7	12.11											
11.15	13.6	12.11	12.10	11.16										
11.14	13.5	12.11	12.10	12.9	11.16	11.15								
11.13	13.4	12.11	12.10	12.9	12.8	11.16	11.15	11.14						
11.12	12.11	12.10	12.9	12.8	12.7	11.16	11.15	11.14	11.13					
11.11	12.11	12.10	12.9	12.8	12.7	12.6	11.16	11.15	11.14	11.13	11.12			
11.9	12.11	12.10	12.9	12.8	12.7	12.6	12.4	11.16	11.15	11.14	11.13	11.12	11.11	
10.21	14.3	13.7	12.11	11.16										
10.20	13.6	12.10	11.16	11.15	10.21									
10.19	13.5	12.9	11.16	11.15	11.14	10.21	10.20							
10.18	13.4	12.8	11.16	11.15	11.14	11.13	10.21	10.20	10.19					
10.17	11.16	11.15	11.14	11.13	11.12	10.21	10.20	10.19	10.18					
10.16	11.16	11.15	11.14	11.13	11.12	11.11	10.21	10.20	10.19	10.18	10.17			
10.14	11.16	11.15	11.14	11.13	11.12	11.11	11.9	10.20	10.19	10.18	10.17	10.16		
9.6.22	14.3	13.4	12.8	11.13										

For any version that you're considering, always check the availability of your cluster's DB instance class. For more information about DB instance classes, including which ones are Graviton2-based and which ones are Intel-based, see [Aurora DB instance classes \(p. 56\)](#).

## Getting a list of available versions in your AWS Region

You can get a list of engine versions available as upgrade targets for your Aurora PostgreSQL DB by querying your AWS Region using the following [describe-db-engine-versions](#) AWS CLI command, as follows.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine aurora-postgresql \
--engine-version 12.10 \
--query 'DBEngineVersions[].[ValidUpgradeTarget[?IsMajorVersionUpgrade == `true`].{EngineVersion:EngineVersion}}' \
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine aurora-postgresql ^
--engine-version 12.10 ^
--query "DBEngineVersions[?ValidUpgradeTarget[?IsMajorVersionUpgrade == `true`].
{EngineVersion:EngineVersion}" ^
--output text
```

In some cases, the version that you want to upgrade to isn't a target for your current version. In such cases, use the information in the [versions table](#) to perform minor version upgrades until your cluster is at a version that has your chosen target in its row of targets.

## Before upgrading your production DB cluster to a new major version

Each new major version includes enhancements to the query optimizer that are designed to improve performance. However, your workload might include queries that result in a worse performing plan in the new version. That's why we recommend that you test and review performance before upgrading in production. You can manage query plan stability across versions by using the Query Plan Management (QPM) extension, as detailed in [Ensuring plan stability after a major version upgrade \(p. 1296\)](#).

Before upgrading your production Aurora PostgreSQL DB clusters to a new major version, we strongly recommend that you test the upgrade to verify that all your applications work correctly:

1. Have a version-compatible parameter group ready.

If you are using a custom DB instance or DB cluster parameter group, you can choose from two options:

- a. Specify the default DB instance, DB cluster parameter group, or both for the new DB engine version.
- b. Create your own custom parameter group for the new DB engine version.

If you associate a new DB instance or DB cluster parameter group as a part of the upgrade request, make sure to reboot the database after the upgrade completes to apply the parameters. If a DB instance needs to be rebooted to apply the parameter group changes, the instance's parameter group status shows `pending-reboot`. You can view an instance's parameter group status in the console or by using a CLI command such as [describe-db-instances](#) or [describe-db-clusters](#).

2. Check for unsupported usage:

- Commit or roll back all open prepared transactions before attempting an upgrade. You can use the following query to verify that there are no open prepared transactions on your instance.

```
SELECT count(*) FROM pg_catalog.pg_prepared_xacts;
```

- Remove all uses of the `reg*` data types before attempting an upgrade. Except for `regtype` and `regclass`, you can't upgrade the `reg*` data types. The `pg_upgrade` utility (used by Amazon Aurora to do the upgrade) can't persist this data type. To learn more about this utility, see [pg\\_upgrade](#) in the PostgreSQL documentation.

To verify that there are no uses of unsupported `reg*` data types, use the following query for each database.

```
SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n,
pg_catalog.pg_attribute a
WHERE c.oid = a.attrelid
AND NOT a.attisdropped
AND a.atttypid IN ('pg_catalog.regproc'::pg_catalog.regtype,
'pg_catalog.regprocedure'::pg_catalog.regtype,
```

```
'pg_catalog.regoper)::pg_catalog.regtype,  
'pg_catalog.regoperator)::pg_catalog.regtype,  
'pg_catalog.regconfig)::pg_catalog.regtype,  
'pg_catalog.regdictionary)::pg_catalog.regtype)  
AND c.relnamespace = n.oid  
AND n.nspname NOT IN ('pg_catalog', 'information_schema');
```

- If you are upgrading an Aurora PostgreSQL version 10.18 or higher DB cluster that has the pgRouting extension installed, drop the extension before upgrading to version 12.4 or higher.

### 3. Drop logical replication slots.

The upgrade process can't proceed if the Aurora PostgreSQL DB cluster is using any logical replication slots. Logical replication slots are typically used for short-term data migration tasks, such as migrating data using AWS DMS or for replicating tables from the database to data lakes, BI tools, or other targets. Before upgrading, make sure that you know the purpose of any logical replication slots that exist, and confirm that it's okay to delete them. You can check for logical replication slots using the following query:

```
SELECT * FROM pg_replication_slots;
```

If logical replication slots are still being used, you shouldn't delete them, and you can't proceed with the upgrade. However, if the logical replication slots aren't needed, you can delete them using the following SQL:

```
SELECT pg_drop_replication_slot(slot_name);
```

### 4. Perform a backup.

The upgrade process creates a DB cluster snapshot of your DB cluster during upgrading. If you also want to do a manual backup before the upgrade process, see [Creating a DB cluster snapshot \(p. 373\)](#) for more information.

### 5. Upgrade certain extensions to the latest available version before performing the major version upgrade. The extensions to update include the following:

- pgRouting
- postgis\_raster
- postgis\_tiger\_geocoder
- postgis\_topology
- address\_standardizer
- address\_standardizer\_data\_us

Run the following command for each extension that's currently installed.

```
ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version'
```

For more information, see [Upgrading PostgreSQL extensions \(p. 1428\)](#). To learn more about upgrading PostGIS, see [Step 6: Upgrade the PostGIS extension \(p. 1323\)](#).

### 6. If you're upgrading to version 11.x, drop the extensions that it doesn't support before performing the major version upgrade. The extensions to drop include:

- chkpass
- tsearch2

### 7. Drop unknown data types, depending on your target version.

PostgreSQL version 10 doesn't support the unknown data type. If a version 9.6 database uses the unknown data type, an upgrade to version 10 shows an error message such as the following.

```
Database instance is in a state that cannot be upgraded: PreUpgrade checks failed:  
The instance could not be upgraded because the 'unknown' data type is used in user  
tables.  
Please remove all usages of the 'unknown' data type and try again."
```

To find the unknown data type in your database so that you can remove such columns or change them to supported data types, use the following SQL code for each database.

```
SELECT n.nspname, c.relname, a.attname  
  FROM pg_catalog.pg_class c,  
       pg_catalog.pg_namespace n,  
       pg_catalog.pg_attribute a  
 WHERE c.oid = a.attrelid AND NOT a.attisdropped AND  
       a.atttypid = 'pg_catalog.unknown)::pg_catalog.reftype AND  
       c.relkind IN ('r','m','c') AND  
       c.relnamespace = n.oid AND  
       n.nspname !~ '^pg_temp_' AND  
       n.nspname !~ '^pg_toast_temp_' AND n.nspname NOT IN ('pg_catalog',  
       'information_schema');
```

#### 8. Perform a dry-run upgrade.

We highly recommend testing a major version upgrade on a duplicate of your production database before trying the upgrade on your production database. To create a duplicate test instance, you can either restore your database from a recent snapshot or clone your database. For more information, see [Restoring from a snapshot \(p. 376\)](#) or [Cloning a volume for an Amazon Aurora DB cluster \(p. 280\)](#).

For more information, see [Upgrading the Aurora PostgreSQL engine to a new major version \(p. 1422\)](#).

#### 9. Upgrade your production instance.

When your dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see [Upgrading the Aurora PostgreSQL engine to a new major version \(p. 1422\)](#).

##### Note

During the upgrade process, you can't do a point-in-time restore of your cluster. Aurora PostgreSQL takes a DB cluster snapshot during the upgrade process if your backup retention period is greater than 0. You can perform a point-in-time restore to times before the upgrade began and after the automatic snapshot of your instance has completed.

For information about an upgrade in progress, you can use Amazon RDS to view two logs that the pg\_upgrade utility produces. These are pg\_upgrade\_internal.log and pg\_upgrade\_server.log. Amazon Aurora appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see [Monitoring Amazon Aurora log files \(p. 597\)](#).

10 Upgrade PostgreSQL extensions. The PostgreSQL upgrade process doesn't upgrade any PostgreSQL extensions. For more information, see [Upgrading PostgreSQL extensions \(p. 1428\)](#).

After you complete a major version upgrade, we recommend the following:

- Run the ANALYZE operation to refresh the pg\_statistic table.
- If you upgraded to PostgreSQL version 10, run REINDEX on any hash indexes you have. Hash indexes were changed in version 10 and must be rebuilt. To locate invalid hash indexes, run the following SQL for each database that contains hash indexes.

```
SELECT idx.indrelid::regclass AS table_name,
```

```
idx.indexrelid::regclass AS index_name
FROM pg_catalog.pg_index idx
JOIN pg_catalog.pg_class cls ON cls.oid = idx.indexrelid
JOIN pg_catalog.pg_am am ON am.oid = cls.relam
WHERE am.amname = 'hash'
AND NOT idx.indisvalid;
```

- We recommend that you test your application on the upgraded database with a similar workload to verify that everything works as expected. After the upgrade is verified, you can delete this test instance.

## Upgrading the Aurora PostgreSQL engine to a new major version

When you initiate the upgrade process to a new major version, Aurora PostgreSQL takes a snapshot of the Aurora DB cluster before it makes any changes to your cluster. This snapshot is created for major version upgrades only, not minor version upgrades. When the upgrade process completes, you can find this snapshot among the manual snapshots listed under **Snapshots** in the RDS console. The snapshot name includes `preupgrade` as its prefix, the name of your Aurora PostgreSQL DB cluster, the source version, the target version, and the date and timestamp, as shown in the following example.

```
preupgrade-docs-lab-apg-global-db-12-8-to-13-6-2022-05-19-00-19
```

After the upgrade completes, you can use the snapshot that Aurora created and stored in your manual snapshot list to restore the DB cluster to its previous version, if necessary.

### Tip

In general, snapshots provide many ways to restore your Aurora DB cluster to various points in time. To learn more, see [Restoring from a DB cluster snapshot \(p. 375\)](#) and [Restoring a DB cluster to a specified time \(p. 415\)](#).

During the major version upgrade process, Aurora allocates a volume and clones the source Aurora PostgreSQL DB cluster. If the upgrade fails for any reason, Aurora PostgreSQL uses the clone to roll back the upgrade. After more than 15 clones of a source volume are allocated, subsequent clones become full copies and take longer. This can cause the upgrade process also to take longer. If Aurora PostgreSQL rolls back the upgrade, be aware of the following:

- You might see billing entries and metrics for both the original volume and the cloned volume allocated during the upgrade. Aurora PostgreSQL cleans up the extra volume after the cluster backup retention window is beyond the time of the upgrade.
- The next cross-Region snapshot copy from this cluster will be a full copy instead of an incremental copy.

To safely upgrade the DB instances that make up your cluster, Aurora PostgreSQL uses the `pg_upgrade` utility. After the writer upgrade completes, each reader instance experiences a brief outage while it's upgraded to the new major version. To learn more about this PostgreSQL utility, see [pg\\_upgrade](#) in the PostgreSQL documentation.

You can upgrade your Aurora PostgreSQL DB cluster to a new version by using the AWS Management Console, the AWS CLI, or the RDS API.

### Console

#### To upgrade the engine version of a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB cluster that you want to upgrade.

3. Choose **Modify**. The **Modify DB cluster** page appears.
4. For **Engine version**, choose the new version.
5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see [Modifying an Amazon Aurora DB cluster \(p. 248\)](#).
7. On the confirmation page, review your changes. If they are correct, choose **Modify Cluster** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

## AWS CLI

To upgrade the engine version of a DB cluster, use the [modify-db-cluster](#) AWS CLI command. Specify the following parameters:

- **--db-cluster-identifier** – The name of the DB cluster.
- **--engine-version** – The version number of the database engine to upgrade to. For information about valid engine versions, use the AWS CLI [describe-db-engine-versions](#) command.
- **--allow-major-version-upgrade** – A required flag when the **--engine-version** parameter is a different major version than the DB cluster's current major version.
- **--no-apply-immediately** – Apply changes during the next maintenance window. To apply changes immediately, use **--apply-immediately**.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
  --db-cluster-identifier mydbcluster \
  --engine-version new_version \
  --allow-major-version-upgrade \
  --no-apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbcluster ^
  --engine-version new_version ^
  --allow-major-version-upgrade ^
  --no-apply-immediately
```

## RDS API

To upgrade the engine version of a DB cluster, use the [ModifyDBCluster](#) operation. Specify the following parameters:

- **DBClusterIdentifier** – The name of the DB cluster, for example *mydbcluster*.
- **EngineVersion** – The version number of the database engine to upgrade to. For information about valid engine versions, use the [DescribeDBEngineVersions](#) operation.
- **AllowMajorVersionUpgrade** – A required flag when the **EngineVersion** parameter is a different major version than the DB cluster's current major version.
- **ApplyImmediately** – Whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

## Major upgrades for global databases

For an Aurora global database cluster, the upgrade process upgrades all DB clusters that make up your Aurora global database at the same time. It does so to ensure that each runs the same Aurora PostgreSQL version. It also ensures that any changes to system tables, data file formats, and so on, are automatically replicated to all secondary clusters.

To upgrade a global database cluster to a new major version of Aurora PostgreSQL, we recommend that you test your applications on the upgraded version, as detailed in [Before upgrading your production DB cluster to a new major version \(p. 1419\)](#). Be sure to prepare your DB cluster parameter group and DB parameter group settings for each AWS Region in your Aurora global database before the upgrade as detailed in [step 1. of Before upgrading your production DB cluster to a new major version \(p. 1419\)](#).

If your Aurora PostgreSQL global database cluster has a recovery point objective (RPO) set for its `rds.global_db_rpo` parameter, make sure to reset the parameter before upgrading. The major version upgrade process doesn't work if the RPO is turned on. By default, this parameter is turned off. For more information about Aurora PostgreSQL global databases and RPO, see [Managing RPOs for Aurora PostgreSQL-based global databases \(p. 198\)](#).

If you verify that your applications can run as expected on the trial deployment of the new version, you can start the upgrade process. To do so, see [Upgrading the Aurora PostgreSQL engine to a new major version \(p. 1422\)](#). Be sure to choose the top-level item from the **Databases** list in the RDS console, **Global database**, as shown in the following image.

DB identifier	Role	Engine	Region & AZ	Size
docs-lab-apg-aiml	Regional cluster	Aurora PostgreSQL	us-west-1	2 instances
docs-lab-apg-global-db	Global database	Aurora PostgreSQL	2 regions	2 clusters
docs-lab-apg-global-12-7	Primary cluster	Aurora PostgreSQL	us-west-1	2 instances
docs-lab-apg-global-12-7-instance-1	Writer instance	Aurora PostgreSQL	us-west-1c	db.r6g.large
docs-lab-apg-global-12-7-instance-1-us-west-1a	Reader instance	Aurora PostgreSQL	us-west-1a	db.r6g.large
docs-lab-apg-global-db-cluster-northwest	Secondary cluster	Aurora PostgreSQL	us-west-2	2 instances
docs-lab-apg-global-db-instance-north	Reader instance	Aurora PostgreSQL	us-west-2c	db.r6g.large
docs-lab-apg-global-db-instance-north-us-west-2b	Reader instance	Aurora PostgreSQL	us-west-2b	db.r6g.large
docs-lab-apg-main	Regional cluster	Aurora PostgreSQL	us-west-1	2 instances
docs-lab-apg-sless-test-aws-s3	Serverless	Aurora PostgreSQL	us-west-1	0 capacity units

As with any modification, you can confirm that you want the process to proceed when prompted.

RDS > Databases > Modify global database

## Modify global database: docs-lab-apg-global-db

**Summary of modifications**

You are about to submit the following modifications. Only values that will change are displayed. Carefully verify your changes and click Modify global database.

Attribute	Current value	New value
DB engine version	12.8	13.6
DB cluster parameter group	default.aurora-postgresql12	default.aurora-postgresql13
DB parameter group	default.aurora-postgresql12	default.aurora-postgresql13

**⚠ Potential unexpected downtime**  
This upgrade is applied immediately in an asynchronous fashion. If any pending modifications require rebooting your cluster, this upgrade can cause unexpected downtime.

**Note:**  
To schedule modifications in the next maintenance window, modify the DB cluster or DB instance individually.

Cancel Back **Modify global database**

Rather than using the console, you can start the upgrade process by using the AWS CLI or the RDS API. As with the console, you operate on the Aurora global database cluster rather than any of its constituents, as follows:

- Use the [modify-global-cluster](#) AWS CLI command to start the upgrade for your Aurora global database by using the AWS CLI.
- Use the [ModifyGlobalCluster](#) API to start the upgrade.

## How to perform minor version upgrades and apply patches

Minor version upgrades and patches become available in AWS Regions only after rigorous testing. Before releasing upgrades and patches, Aurora PostgreSQL tests to ensure that known security issues, bugs, and other issues that emerge after the release of the minor community version don't disrupt overall Aurora PostgreSQL fleet stability.

As Aurora PostgreSQL makes new minor versions available, the instances that make up your Aurora PostgreSQL DB cluster can be automatically upgraded during your specified maintenance window. For this to happen, your Aurora PostgreSQL DB cluster must have the **Enable auto minor version upgrade** option turned on. All DB instances that make up your Aurora PostgreSQL DB cluster must have the automatic minor version upgrade (AMVU) option turned on so that the minor upgrade to be applied throughout the cluster.

### Tip

Make sure that the **Enable auto minor version upgrade** option is turned on for all PostgreSQL DB instances that make up your Aurora PostgreSQL DB cluster. This option must be turned on for every instance in the DB cluster to work.

You can check the value of the **Enable auto minor version upgrade** option for all your Aurora PostgreSQL DB clusters by using the [describe-db-instances](#) AWS CLI command with the following query.

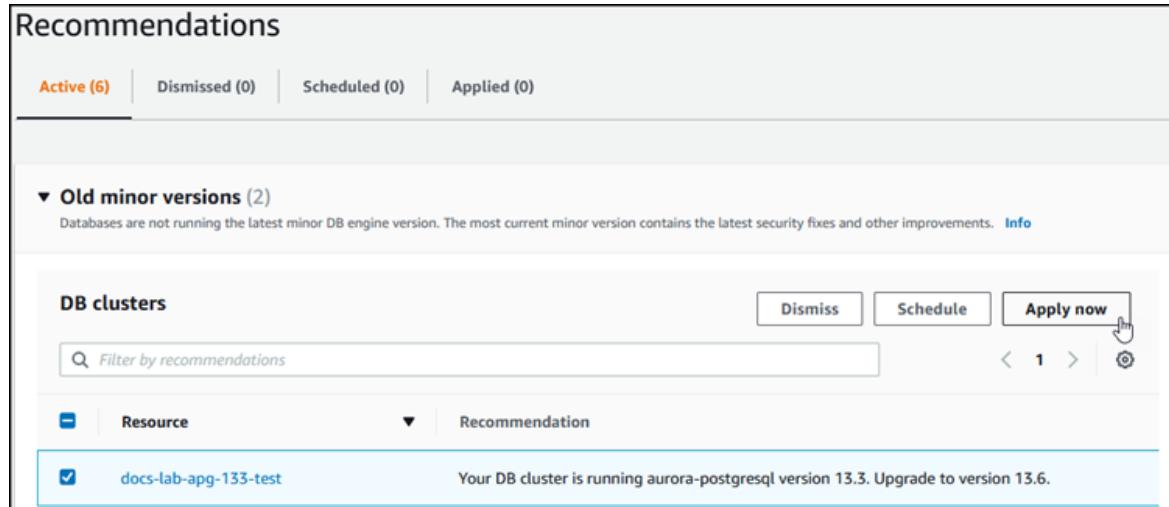

```
aws rds describe-db-instances \
--query '*[].
{DBClusterIdentifier:DBClusterIdentifier,DBInstanceIdentifier:DBInstanceIdentifier,AutoMinorVersionUpgrade:AutoMinorVersionUpgrade}'
```

This query returns a list of all Aurora DB clusters and their instances with a `true` or `false` value for the status of the `AutoMinorVersionUpgrade` setting. The command as shown assumes that you have your AWS CLI configured to target your default AWS Region.

For more information about the AMVU option and how to modify your Aurora DB cluster to use it, see [Automatic minor version upgrades for Aurora DB clusters \(p. 327\)](#).

You can upgrade your Aurora PostgreSQL DB clusters to new minor versions either by responding to maintenance tasks, or by modifying the cluster to use the new version.

You can identify any available upgrades or patches for your Aurora PostgreSQL DB clusters by using the RDS console and opening the **Recommendations** menu. There, you can find a list of various maintenance issues such as **Old minor versions**. Depending on your production environment, you can choose to **Schedule** the upgrade or take immediate action, by choosing **Apply now**, as shown following.

To learn more about how to maintain an Aurora DB cluster, including how to manually apply patches and minor version upgrades, see [Maintaining an Amazon Aurora DB cluster \(p. 321\)](#).

### Minor release upgrades and zero-downtime patching

Upgrading an Aurora PostgreSQL DB cluster involves the possibility of an outage. During the upgrade process, the database is shut down as it's being upgraded. If you start the upgrade while the database is busy, you lose all connections and transactions that the DB cluster is processing. If you wait until the database is idle to perform the upgrade, you might have to wait a long time.

The zero-downtime patching (ZDP) feature improves the upgrading process. With ZDP, both minor version upgrades and patches can be applied with minimal impact to your Aurora PostgreSQL DB cluster. ZDP will be used when applying patches or newer minor version upgrades to Aurora PostgreSQL versions

14.3.1 or higher, 13.7.1 or higher, 12.11.1 or higher, 11.16.1 or higher, and 10.21.1 or higher. That is, upgrading to new minor versions from any of these releases onward uses ZDP.

**Note**

ZDP isn't supported for Aurora PostgreSQL DB clusters that are configured as Aurora Serverless v2, Aurora Serverless v1, Aurora global databases, or Babelfish.

ZDP works by preserving current client connections to your Aurora PostgreSQL DB cluster throughout the Aurora PostgreSQL upgrade process. When ZDP completes successfully, application sessions are preserved and the database engine restarts while the upgrade is still under way. Although the database engine restart can cause a drop in throughput, that typically lasts only for a few seconds or at most, approximately one minute.

In some cases, zero-downtime patching (ZDP) might not succeed. For example, if long-running queries or transactions are in progress, ZDP might need to cancel these to complete. If data definition language (DDL) statements are running or if temporary tables or table locks are in use for any other reason, ZDP might need to cancel the open transaction. Parameter changes that are in a pending state on your Aurora PostgreSQL DB cluster or its instances also interfere with ZDP.

You can find metrics and events for ZDP operations in **Events** page in the console. The events include the start of the ZDP upgrade and completion of the upgrade. In this event you can find how long the process took, and the numbers of preserved and dropped connections that occurred during the restart. You can find details in your database error log.

## Upgrading the Aurora PostgreSQL engine to a new minor version

You can upgrade your Aurora PostgreSQL DB cluster to a new minor version by using the console, the AWS CLI, or the RDS API. Before performing the upgrade, we recommend that you follow the same best practice that we recommend for major version upgrades. As with new major versions, new minor versions can also have optimizer improvements, such as fixes, that can cause query plan regressions. To ensure plan stability, we recommend that you use the Query Plan Management (QPM) extension as detailed in [Ensuring plan stability after a major version upgrade \(p. 1296\)](#).

### Console

#### To upgrade the engine version of your Aurora PostgreSQL DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB cluster that you want to upgrade.
3. Choose **Modify**. The **Modify DB cluster** page appears.
4. For **Engine version**, choose the new version.
5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see [Modifying an Amazon Aurora DB cluster \(p. 248\)](#).
7. On the confirmation page, review your changes. If they are correct, choose **Modify Cluster** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

### AWS CLI

To upgrade the engine version of a DB cluster, use the `modify-db-cluster` AWS CLI command with the following parameters:

- `--db-cluster-identifier` – The name of your Aurora PostgreSQL DB cluster.

- `--engine-version` – The version number of the database engine to upgrade to. For information about valid engine versions, use the AWS CLI [describe-db-engine-versions](#) command.
- `--no-apply-immediately` – Apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately` instead.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
  --db-cluster-identifier mydbcluster \
  --engine-version new_version \
  --no-apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbcluster ^
  --engine-version new_version ^
  --no-apply-immediately
```

## RDS API

To upgrade the engine version of a DB cluster, use the [ModifyDBCluster](#) operation. Specify the following parameters:

- `DBClusterIdentifier` – The name of the DB cluster, for example `mydbcluster`.
- `EngineVersion` – The version number of the database engine to upgrade to. For information about valid engine versions, use the [DescribeDBEngineVersions](#) operation.
- `ApplyImmediately` – Whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

## Upgrading PostgreSQL extensions

Upgrading your Aurora PostgreSQL DB cluster to a new major version doesn't upgrade the PostgreSQL extensions at the same time. For most extensions, you upgrade the extension after the major version upgrade completes. However, in some cases, you upgrade the extension before you upgrade the Aurora PostgreSQL DB engine. For more information, see the [list of extensions to update](#) in [Before upgrading your production DB cluster to a new major version \(p. 1419\)](#).

Installing PostgreSQL extensions requires `rds_superuser` privileges. Typically, an `rds_superuser` delegates permissions over specific extensions to relevant users (roles), to facilitate the management of a given extension. That means that the task of upgrading all the extensions in your Aurora PostgreSQL DB cluster might involve many different users (roles). Keep this in mind especially if you want to automate the upgrade process by using scripts. For more information about PostgreSQL privileges and roles, see [Security with Amazon Aurora PostgreSQL \(p. 1018\)](#).

### Note

For information about upgrading the PostGIS extension version, see [Managing spatial data with the PostGIS extension \(p. 1320\)](#) ([Step 6: Upgrade the PostGIS extension \(p. 1323\)](#)).

To update an extension after an engine upgrade, use the `ALTER EXTENSION UPDATE` command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version';
```

To list your currently installed extensions, use the PostgreSQL `pg_extension` catalog in the following command.

```
SELECT * FROM pg_extension;
```

To view a list of the specific extension versions that are available for your installation, use the PostgreSQL [pg\\_available\\_extension\\_versions](#) view in the following command.

```
SELECT * FROM pg_available_extension_versions;
```

## Aurora PostgreSQL long-term support (LTS) releases

Each new Aurora PostgreSQL version remains available for a certain amount of time for you to use when you create or upgrade a DB cluster. After this period, you must upgrade any clusters that use that version. You can manually upgrade your cluster before the support period ends, or Aurora can automatically upgrade it for you when its Aurora PostgreSQL version is no longer supported.

Aurora designates certain Aurora PostgreSQL versions as long-term support (LTS) releases. Database clusters that use LTS releases can stay on the same version longer and undergo fewer upgrade cycles than clusters that use non-LTS releases. LTS minor versions include only bug fixes (through patch versions); an LTS version doesn't include new features released after its introduction.

Once a year, DB clusters running on an LTS minor version are patched to the latest patch version of the LTS release. We do this patching to help ensure that you benefit from cumulative security and stability fixes. We might patch an LTS minor version more frequently if there are critical fixes, such as for security, that need to be applied.

### Note

To remain on an LTS minor version for the duration of its lifecycle, make sure to turn off **Auto minor version upgrade** for your DB instances. To avoid automatically upgrading your DB cluster from the LTS minor version, set **Auto minor version upgrade** to **No** on all DB instances in your Aurora cluster.

We recommend that you upgrade to the latest release, instead of using the LTS release, for most of your Aurora PostgreSQL clusters. Doing so takes advantage of Aurora as a managed service and gives you access to the latest features and bug fixes. LTS releases are intended for clusters with the following characteristics:

- You can't afford downtime on your Aurora PostgreSQL application for upgrades outside of rare occurrences for critical patches.
- The testing cycle for the cluster and associated applications takes a long time for each update to the Aurora PostgreSQL database engine.
- The database version for your Aurora PostgreSQL cluster has all the DB engine features and bug fixes that your application needs.

The current LTS releases for Aurora PostgreSQL are as follows:

- PostgreSQL 12.9 (Aurora PostgreSQL version 12.9.1). It was released on February 25, 2022. For more information, see [PostgreSQL 12.9 in the Release Notes for Aurora PostgreSQL](#).
- PostgreSQL 11.9 (Aurora PostgreSQL release 3.4). It was released on December 11, 2020. For more information about this version, see [PostgreSQL 11.9, Aurora PostgreSQL release 3.4 in the Release Notes for Aurora PostgreSQL](#).

For information about how to identify Aurora and database engine versions, see [Identifying versions of Amazon Aurora PostgreSQL \(p. 1413\)](#).

# Using Amazon RDS Proxy

By using Amazon RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. By using RDS Proxy, you can also enforce AWS Identity and Access Management (IAM) authentication for databases, and securely store credentials in AWS Secrets Manager.

Using RDS Proxy, you can handle unpredictable surges in database traffic that otherwise might cause issues due to oversubscribing connections or creating new connections at a fast rate. RDS Proxy establishes a database connection pool and reuses connections in this pool without the memory and CPU overhead of opening a new database connection each time. To protect the database against oversubscription, you can control the number of database connections that are created.

RDS Proxy queues or throttles application connections that can't be served immediately from the pool of connections. Although latencies might increase, your application can continue to scale without abruptly failing or overwhelming the database. If connection requests exceed the limits you specify, RDS Proxy rejects application connections (that is, it sheds load). At the same time, it maintains predictable performance for the load that can be served with the available capacity.

You can reduce the overhead to process credentials and establish a secure connection for each new connection. RDS Proxy can handle some of that work on behalf of the database.

RDS Proxy is fully compatible with the engine versions that it supports. You can enable RDS Proxy for most applications with no code changes. For a list of supported engine versions, see [Amazon RDS Proxy \(p. 28\)](#).

## Topics

- [Region and version availability \(p. 1430\)](#)

## Region and version availability

For information about database engine version support and availability of RDS Proxy in a given AWS Region, see [Amazon RDS Proxy \(p. 28\)](#).

# Quotas and limitations for RDS Proxy

The following quotas and limitations apply to RDS Proxy:

- You can have up to 20 proxies for each AWS account ID. If your application requires more proxies, you can request additional proxies by opening a ticket with the AWS Support organization.
- Each proxy can have up to 200 associated Secrets Manager secrets. Thus, each proxy can connect to up to 200 different user accounts at any given time.
- You can create, view, modify, and delete up to 20 endpoints for each proxy. These endpoints are in addition to the default endpoint that's automatically created for each proxy.
- In an Aurora cluster, all of the connections using the default proxy endpoint are handled by the Aurora writer instance. To perform load balancing for read-intensive workloads, you can create a read-only endpoint for a proxy. That endpoint passes connections to the reader endpoint of the cluster. That way, your proxy connections can take advantage of Aurora read scalability. For more information, see [Overview of proxy endpoints \(p. 1458\)](#).

For RDS DB instances in replication configurations, you can associate a proxy only with the writer DB instance, not a read replica.

- You can use RDS Proxy with Aurora Serverless v2 clusters but not with Aurora Serverless v1 clusters.
- Using RDS Proxy with Aurora clusters that are part of an Aurora global database isn't currently supported.
- Your RDS Proxy must be in the same virtual private cloud (VPC) as the database. The proxy can't be publicly accessible, although the database can be. For example, if you're prototyping on a local host, you can't connect to your RDS Proxy unless you set up dedicated networking. This is the case because your local host is outside of the proxy's VPC.

## Note

For Aurora DB clusters, you can turn on cross-VPC access. To do this, create an additional endpoint for a proxy and specify a different VPC, subnets, and security groups with that endpoint. For more information, see [Accessing Aurora and RDS databases across VPCs \(p. 1462\)](#).

- You can't use RDS Proxy with a VPC that has its tenancy set to dedicated.
- If you use RDS Proxy with an RDS DB instance or Aurora DB cluster that has IAM authentication enabled, make sure that all users who connect through a proxy authenticate through user names and passwords. See [Setting up AWS Identity and Access Management \(IAM\) policies \(p. 1440\)](#) for details about IAM support in RDS Proxy.
- You can't use RDS Proxy with custom DNS.
- Each proxy can be associated with a single target DB instance or cluster. However, you can associate multiple proxies with the same DB instance or cluster.
- Any statement with a text size greater than 16 KB causes the proxy to pin the session to the current connection.

The following RDS Proxy limitations apply to MySQL:

- RDS Proxy doesn't support the MySQL sha256\_password and caching\_sha2\_password authentication plugins. These plugins implement SHA-256 hashing for user account passwords.
- Currently, all proxies listen on port 3306 for MySQL. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MySQL databases in EC2 instances.
- You can't use RDS Proxy with an RDS for MySQL DB instance that has the `read_only` parameter in its DB parameter group set to 1.
- RDS Proxy doesn't support MySQL compressed mode. For example, it doesn't support the compression used by the `--compress` or `-C` options of the `mysql` command.

- Some SQL statements and functions can change the connection state without causing pinning. For the most current pinning behavior, see [Avoiding pinning \(p. 1455\)](#).

**Important**

For proxies associated with MySQL databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

The following RDS Proxy limitations apply to PostgreSQL:

- RDS Proxy doesn't support session pinning filters for PostgreSQL.
- RDS Proxy doesn't support PostgreSQL SCRAM-SHA-256 authentication.
- Currently, all proxies listen on port 5432 for PostgreSQL.
- For PostgreSQL, RDS Proxy doesn't currently support canceling a query from a client by issuing a `CancelRequest`. This is the case for example, when you cancel a long-running query in an interactive `psql` session by using `Ctrl+C`.
- The results of the PostgreSQL function `lastval` aren't always accurate. As a work-around, use the [INSERT](#) statement with the `RETURNING` clause.
- RDS Proxy doesn't multiplex connections when your client application drivers use the PostgreSQL extended query protocol.

## Planning where to use RDS Proxy

You can determine which of your DB instances, clusters, and applications might benefit the most from using RDS Proxy. To do so, consider these factors:

- Any DB instance or cluster that encounters "too many connections" errors is a good candidate for associating with a proxy. The proxy enables applications to open many client connections, while the proxy manages a smaller number of long-lived connections to the DB instance or cluster.
- For DB instances or clusters that use smaller AWS instance classes, such as T2 or T3, using a proxy can help avoid out-of-memory conditions. It can also help reduce the CPU overhead for establishing connections. These conditions can occur when dealing with large numbers of connections.
- You can monitor certain Amazon CloudWatch metrics to determine whether a DB instance or cluster is approaching certain types of limit. These limits are for the number of connections and the memory associated with connection management. You can also monitor certain CloudWatch metrics to determine whether a DB instance or cluster is handling many short-lived connections. Opening and closing such connections can impose performance overhead on your database. For information about the metrics to monitor, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 1467\)](#).
- AWS Lambda functions can also be good candidates for using a proxy. These functions make frequent short database connections that benefit from connection pooling offered by RDS Proxy. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- Applications that typically open and close large numbers of database connections and don't have built-in connection pooling mechanisms are good candidates for using a proxy.
- Applications that keep a large number of connections open for long periods are typically good candidates for using a proxy. Applications in industries such as software as a service (SaaS) or ecommerce often minimize the latency for database requests by leaving connections open. With RDS Proxy, an application can keep more connections open than it can when connecting directly to the DB instance or cluster.
- You might not have adopted IAM authentication and Secrets Manager due to the complexity of setting up such authentication for all DB instances and clusters. If so, you can leave the existing

authentication methods in place and delegate the authentication to a proxy. The proxy can enforce the authentication policies for client connections for particular applications. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.

- RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). To ensure overall high availability for your database, deploy your Amazon RDS DB instance or Aurora cluster in a Multi-AZ configuration.

## RDS Proxy concepts and terminology

You can simplify connection management for your Amazon RDS DB instances and Amazon Aurora DB clusters by using RDS Proxy.

RDS Proxy handles the network traffic between the client application and the database. It does so in an active way first by understanding the database protocol. It then adjusts its behavior based on the SQL operations from your application and the result sets from the database.

RDS Proxy reduces the memory and CPU overhead for connection management on your database. The database needs less memory and CPU resources when applications open many simultaneous connections. It also doesn't require logic in your applications to close and reopen connections that stay idle for a long time. Similarly, it requires less application logic to reestablish connections in case of a database problem.

The infrastructure for RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). The computation, memory, and storage for RDS Proxy are independent of your RDS DB instances and Aurora DB clusters. This separation helps lower overhead on your database servers, so that they can devote their resources to serving database workloads. The RDS Proxy compute resources are serverless, automatically scaling based on your database workload.

### Topics

- [Overview of RDS Proxy concepts \(p. 1433\)](#)
- [Connection pooling \(p. 1434\)](#)
- [RDS Proxy security \(p. 1434\)](#)
- [Failover \(p. 1436\)](#)
- [Transactions \(p. 1436\)](#)

## Overview of RDS Proxy concepts

RDS Proxy handles the infrastructure to perform connection pooling and the other features described in the sections that follow. You see the proxies represented in the RDS console on the [Proxies](#) page.

Each proxy handles connections to a single RDS DB instance or Aurora DB cluster. The proxy automatically determines the current writer instance for RDS Multi-AZ DB instances and Aurora provisioned clusters. For Aurora multi-master clusters, the proxy connects to one of the writer instances and uses the other writer instances as hot standby targets.

The connections that a proxy keeps open and available for your database application to use make up the *connection pool*.

By default, RDS Proxy can reuse a connection after each transaction in your session. This transaction-level reuse is called *multiplexing*. When RDS Proxy temporarily removes a connection from the connection pool to reuse it, that operation is called *borrowing* the connection. When it's safe to do so, RDS Proxy returns that connection to the connection pool.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called *pinning*.

A proxy has a default endpoint. You connect to this endpoint when you work with an RDS DB instance or Aurora DB cluster, instead of connecting to the read/write endpoint that connects directly to the instance or cluster. The special-purpose endpoints for an Aurora cluster remain available for you to use. For Aurora DB clusters, you can also create additional read/write and read-only endpoints. For more information, see [Overview of proxy endpoints \(p. 1458\)](#).

For example, you can still connect to the cluster endpoint for read/write connections without connection pooling. You can still connect to the reader endpoint for load-balanced read-only connections. You can still connect to the instance endpoints for diagnosis and troubleshooting of specific DB instances within an Aurora cluster. If you are using other AWS services such as AWS Lambda to connect to RDS databases, you change their connection settings to use the proxy endpoint. For example, you specify the proxy endpoint to allow Lambda functions to access your database while taking advantage of RDS Proxy functionality.

Each proxy contains a target group. This *target group* embodies the RDS DB instance or Aurora DB cluster that the proxy can connect to. For an Aurora cluster, by default the target group is associated with all the DB instances in that cluster. That way, the proxy can connect to whichever Aurora DB instance is promoted to be the writer instance in the cluster. The RDS DB instance associated with a proxy, or the Aurora DB cluster and its instances, are called the *targets* of that proxy. For convenience, when you create a proxy through the console, RDS Proxy also creates the corresponding target group and registers the associated targets automatically.

An *engine family* is a related set of database engines that use the same DB protocol. You choose the engine family for each proxy that you create.

## Connection pooling

Each proxy performs connection pooling for the writer instance of its associated RDS or Aurora database. *Connection pooling* is an optimization that reduces the overhead associated with opening and closing connections and with keeping many connections open simultaneously. This overhead includes memory needed to handle each new connection. It also involves CPU overhead to close each connection and open a new one, such as Transport Layer Security/Secure Sockets Layer (TLS/SSL) handshaking, authentication, negotiating capabilities, and so on. Connection pooling simplifies your application logic. You don't need to write application code to minimize the number of simultaneous open connections.

Each proxy also performs connection multiplexing, also known as connection reuse. With *multiplexing*, RDS Proxy performs all the operations for a transaction using one underlying database connection, then can use a different connection for the next transaction. You can open many simultaneous connections to the proxy, and the proxy keeps a smaller number of connections open to the DB instance or cluster. Doing so further minimizes the memory overhead for connections on the database server. This technique also reduces the chance of "too many connections" errors.

## RDS Proxy security

RDS Proxy uses the existing RDS security mechanisms such as TLS/SSL and AWS Identity and Access Management (IAM). For general information about those security features, see [Security in Amazon Aurora \(p. 1634\)](#). If you aren't familiar with how RDS and Aurora work with authentication, authorization, and other areas of security, make sure to familiarize yourself with how RDS and Aurora work with those areas first.

RDS Proxy can act as an additional layer of security between client applications and the underlying database. For example, you can connect to the proxy using TLS 1.2, even if the underlying DB instance supports only TLS 1.0 or 1.1. You can connect to the proxy using an IAM role, even if the proxy connects to the database using the native user and password authentication method. By using this technique, you

can enforce strong authentication requirements for database applications without a costly migration effort for the DB instances themselves.

You store the database credentials used by RDS Proxy in AWS Secrets Manager. Each database user for the RDS DB instance or Aurora DB cluster accessed by a proxy must have a corresponding secret in Secrets Manager. You can also set up IAM authentication for users of RDS Proxy. By doing so, you can enforce IAM authentication for database access even if the databases use native password authentication. We recommend using these security features instead of embedding database credentials in your application code.

## Using TLS/SSL with RDS Proxy

You can connect to RDS Proxy using the TLS/SSL protocol.

### Note

RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you use RDS Proxy, when you rotate your TLS/SSL certificate you don't need to update applications that use RDS Proxy connections.

To enforce TLS for all connections between the proxy and your database, you can specify a setting **Require Transport Layer Security** when you create or modify a proxy.

RDS Proxy can also ensure that your session uses TLS/SSL between your client and the RDS Proxy endpoint. To have RDS Proxy do so, specify the requirement on the client side. SSL session variables are not set for SSL connections to a database using RDS Proxy.

- For RDS for MySQL and Aurora MySQL, specify the requirement on the client side with the `--ssl-mode` parameter when you run the `mysql` command.
- For Amazon RDS PostgreSQL and Aurora PostgreSQL, specify `sslmode=require` as part of the `conninfo` string when you run the `psql` command.

RDS Proxy supports TLS protocol version 1.0, 1.1, and 1.2. You can connect to the proxy using a higher version of TLS than you use in the underlying database.

By default, client programs establish an encrypted connection with RDS Proxy, with further control available through the `--ssl-mode` option. From the client side, RDS Proxy supports all SSL modes.

For the client, the SSL modes are the following:

### PREFERRED

SSL is the first choice, but it isn't required.

### DISABLED

No SSL is allowed.

### REQUIRED

Enforce SSL.

### VERIFY\_CA

Enforce SSL and verify the certificate authority (CA).

### VERIFY\_IDENTITY

Enforce SSL and verify the CA and CA hostname.

When using a client with `--ssl-mode VERIFY_CA` or `VERIFY_IDENTITY`, specify the `--ssl-ca` option pointing to a CA in `.pem` format. For the `.pem` file to use, download all root CA PEMs from [Amazon Trust Services](#) and place them into a single `.pem` file.

RDS Proxy uses wildcard certificates, which apply to both a domain and its subdomains. If you use the `mysql` client to connect with SSL mode `VERIFY_IDENTITY`, currently you must use the MySQL 8.0-compatible `mysql` command.

## Failover

*Failover* is a high-availability feature that replaces a database instance with another one when the original instance becomes unavailable. A failover might happen because of a problem with a database instance. It might also be part of normal maintenance procedures, such as during a database upgrade. Failover applies to RDS DB instances in a Multi-AZ configuration, and Aurora DB clusters with one or more reader instances in addition to the writer instance.

Connecting through a proxy makes your application more resilient to database failovers. When the original DB instance becomes unavailable, RDS Proxy connects to the standby database without dropping idle application connections. Doing so helps to speed up and simplify the failover process. The result is faster failover that's less disruptive to your application than a typical reboot or database problem.

Without RDS Proxy, a failover involves a brief outage. During the outage, you can't perform write operations on that database. Any existing database connections are disrupted and your application must reopen them. The database becomes available for new connections and write operations when a read-only DB instance is promoted to take the place of the one that's unavailable.

During DB failovers, RDS Proxy continues to accept connections at the same IP address and automatically directs connections to the new primary DB instance. Clients connecting through RDS Proxy are not susceptible to the following:

- Domain Name System (DNS) propagation delays on failover.
- Local DNS caching.
- Connection timeouts.
- Uncertainty about which DB instance is the current writer.
- Waiting for a query response from a former writer that became unavailable without closing connections.

For applications that maintain their own connection pool, going through RDS Proxy means that most connections stay alive during failovers or other disruptions. Only connections that are in the middle of a transaction or SQL statement are canceled. RDS Proxy immediately accepts new connections. When the database writer is unavailable, RDS Proxy queues up incoming requests.

For applications that don't maintain their own connection pools, RDS Proxy offers faster connection rates and more open connections. It offloads the expensive overhead of frequent reconnects from the database. It does so by reusing database connections maintained in the RDS Proxy connection pool. This approach is particularly important for TLS connections, where setup costs are significant.

## Transactions

All the statements within a single transaction always use the same underlying database connection. The connection becomes available for use by a different session when the transaction ends. Using the transaction as the unit of granularity has the following consequences:

- Connection reuse can happen after each individual statement when the RDS for MySQL or Aurora MySQL `autocommit` setting is enabled.
- Conversely, when the `autocommit` setting is disabled, the first statement you issue in a session begins a new transaction. Thus, if you enter a sequence of `SELECT`, `INSERT`, `UPDATE`, and other data manipulation language (DML) statements, connection reuse doesn't happen until you issue a `COMMIT`, `ROLLBACK`, or otherwise end the transaction.

- Entering a data definition language (DDL) statement causes the transaction to end after that statement completes.

RDS Proxy detects when a transaction ends through the network protocol used by the database client application. Transaction detection doesn't rely on keywords such as `COMMIT` or `ROLLBACK` appearing in the text of the SQL statement.

In some cases, RDS Proxy might detect a database request that makes it impractical to move your session to a different connection. In these cases, it turns off multiplexing for that connection the remainder of your session. The same rule applies if RDS Proxy can't be certain that multiplexing is practical for the session. This operation is called *pinning*. For ways to detect and minimize pinning, see [Avoiding pinning \(p. 1455\)](#).

## Getting started with RDS Proxy

In the following sections, you can find how to set up RDS Proxy. You can also find how to set the related security options that control who can access each proxy and how each proxy connects to DB instances.

- [Creating an RDS Proxy \(p. 1442\)](#)
- [Viewing an RDS Proxy \(p. 1445\)](#)
- [Connecting to a database through RDS Proxy \(p. 1446\)](#)

## Setting up network prerequisites

Using RDS Proxy requires you to have a common virtual private cloud (VPC) between your Aurora DB cluster or RDS DB instance and RDS Proxy. This VPC should have a minimum of two subnets that are in different Availability Zones. Your account can either own these subnets or share them with other accounts. For information about VPC sharing, see [Work with shared VPCs](#). Your client application resources such as Amazon EC2, Lambda, or Amazon ECS can be in the same VPC or in a separate VPC from the proxy. Note that if you've successfully connected to any RDS DB instances or Aurora DB clusters, you already have the required network resources.

If you're just getting started with RDS or Aurora, you can learn the basics of connecting to a database by following the procedures in [Setting up your environment for Amazon Aurora \(p. 87\)](#). You can also follow the tutorial in [Getting started with Amazon Aurora \(p. 93\)](#).

The following Linux example shows AWS CLI commands that examine the VPCs and subnets owned by your AWS account. In particular, you pass subnet IDs as parameters when you create a proxy using the CLI.

```
aws ec2 describe-vpcs
aws ec2 describe-internet-gateways
aws ec2 describe-subnets --query '*[].[VpcId,SubnetId]' --output text | sort
```

The following Linux example shows AWS CLI commands to determine the subnet IDs corresponding to a specific Aurora DB cluster or RDS DB instance. For an Aurora cluster, first you find the ID for one of the associated DB instances. You can extract the subnet IDs used by that DB instance by examining

the nested fields within the `DBSubnetGroup` and `Subnets` attributes in the describe output for the DB instance. You specify some or all of those subnet IDs when setting up a proxy for that database server.

```
$ # Optional first step, only needed if you're starting from an Aurora cluster. Find the ID
of any DB instance in the cluster.
$ aws rds describe-db-clusters --db-cluster-identifier my_cluster_id --query '*[]'.
[DBClusterMembers][0][0].DBInstanceIdentifier' --output text
my_instance_id
instance_id_2
instance_id_3
...
$ # From the DB instance, trace through the DBSubnetGroup and Subnets to find the subnet
IDs.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[]'.
[DBSubnetGroup][0][0][Subnets][0][*].SubnetIdentifier' --output text
subnet_id_1
subnet_id_2
subnet_id_3
...
```

As an alternative, you can first find the VPC ID for the DB instance. Then you can examine the VPC to find its subnets. The following Linux example shows how.

```
$ # From the DB instance, find the VPC.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[]'.
[DBSubnetGroup][0][0].VpcId' --output text
my_vpc_id

$ aws ec2 describe-subnets --filters Name=vpc-id,Values=my_vpc_id --query '*[].[SubnetId]'
--output text
subnet_id_1
subnet_id_2
subnet_id_3
subnet_id_4
subnet_id_5
subnet_id_6
```

## Setting up database credentials in AWS Secrets Manager

For each proxy that you create, you first use the Secrets Manager service to store sets of user name and password credentials. You create a separate Secrets Manager secret for each database user account that the proxy connects to on the RDS DB instance or Aurora DB cluster.

In Secrets Manager, you create these secrets with values for the `username` and `password` fields. Doing so allows the proxy to connect to the corresponding database users on whichever RDS DB instances or Aurora DB clusters that you associate with the proxy. To do this, you can use the setting **Credentials for other database**, **Credentials for RDS database**, or **Other type of secrets**. Fill in the appropriate values for the **User name** and **Password** fields, and placeholder values for any other required fields. The proxy ignores other fields such as **Host** and **Port** if they're present in the secret. Those details are automatically supplied by the proxy.

You can also choose **Other type of secrets**. In this case, you create the secret with keys named `username` and `password`.

Because the secrets used by your proxy aren't tied to a specific database server, you can reuse a secret across multiple proxies if you use the same credentials across multiple database servers. For example, you might use the same credentials across a group of development and test servers.

To connect through the proxy as a specific user, make sure that the password associated with a secret matches the database password for that user. If there's a mismatch, you can update the associated secret in Secrets Manager. In this case, you can still connect to other accounts where the secret credentials and the database passwords do match.

When you create a proxy through the AWS CLI or RDS API, you specify the Amazon Resource Names (ARNs) of the corresponding secrets for all the DB user accounts that the proxy can access. In the AWS Management Console, you choose the secrets by their descriptive names.

For instructions about creating secrets in Secrets Manager, see the [Creating a secret](#) page in the Secrets Manager documentation. Use one of the following techniques:

- Use [Secrets Manager](#) in the console.
- To use the CLI to create a Secrets Manager secret for use with RDS Proxy, use a command such as the following.

```
aws secretsmanager create-secret \
--name "secret_name"
--description "secret_description"
--region region_name
--secret-string '{"username":"db_user","password":"db_user_password"}'
```

For example, the following commands create Secrets Manager secrets for two database users, one named `admin` and the other named `app-user`.

```
aws secretsmanager create-secret \
--name admin_secret_name --description "db admin user" \
--secret-string '{"username":"admin","password":"choose_your_own_password"}'

aws secretsmanager create-secret \
--name proxy_secret_name --description "application user" \
--secret-string '{"username":"app-user","password":"choose_your_own_password"}'
```

To see the secrets owned by your AWS account, use a command such as the following.

```
aws secretsmanager list-secrets
```

When you create a proxy using the CLI, you pass the Amazon Resource Names (ARNs) of one or more secrets to the `--auth` parameter. The following Linux example shows how to prepare a report with only the name and ARN of each secret owned by your AWS account. This example uses the `--output table` parameter that is available in AWS CLI version 2. If you are using AWS CLI version 1, use `--output text` instead.

```
aws secretsmanager list-secrets --query '*[].[Name,ARN]' --output table
```

To verify that you stored the correct credentials and in the right format in a secret, use a command such as the following. Substitute the short name or the ARN of the secret for `your_secret_name`.

```
aws secretsmanager get-secret-value --secret-id your_secret_name
```

The output should include a line displaying a JSON-encoded value like the following.

```
"SecretString": "{\"username\":\"your_username\",\"password\":\"your_password\"}",
```

# Setting up AWS Identity and Access Management (IAM) policies

After you create the secrets in Secrets Manager, you create an IAM policy that can access those secrets. For general information about using IAM with RDS and Aurora, see [Identity and access management for Amazon Aurora \(p. 1653\)](#).

## Tip

The following procedure applies if you use the IAM console. If you use the AWS Management Console for RDS, RDS can create the IAM policy for you automatically. In that case, you can skip the following procedure.

### To create an IAM policy that accesses your Secrets Manager secrets for use with your proxy

1. Sign in to the IAM console. Follow the **Create role** process, as described in [Creating IAM roles](#). Include the **Add Role to Database** step.
2. For the new role, perform the **Add inline policy** step. Use the same general procedures as in [Editing IAM policies](#). Paste the following JSON into the JSON text box. Substitute your own account ID. Substitute your AWS Region for us-east-2. Substitute the Amazon Resource Names (ARNs) for the secrets that you created. For the kms:Decrypt action, substitute the ARN of the default AWS KMS key or your own KMS key depending on which one you used to encrypt the Secrets Manager secrets.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "VisualEditor0",  
            "Effect": "Allow",  
            "Action": "secretsmanager:GetSecretValue",  
            "Resource": [  
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",  
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_2"  
            ]  
        },  
        {  
            "Sid": "VisualEditor1",  
            "Effect": "Allow",  
            "Action": "kms:Decrypt",  
            "Resource": "arn:aws:kms:us-east-2:account_id:key/key_id",  
            "Condition": {  
                "StringEquals": {  
                    "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"  
                }  
            }  
        }  
    ]  
}
```

3. Edit the trust policy for this IAM role. Paste the following JSON into the JSON text box.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "",  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "rds.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

```
        ]  
    }  
}
```

The following commands perform the same operation through the AWS CLI.

```
PREFIX=choose_an_identifier

aws iam create-role --role-name choose_role_name \
--assume-role-policy-document '{"Version":"2012-10-17","Statement":\
[{"Effect":"Allow","Principal":{"Service":\
["rds.amazonaws.com"]},"Action":"sts:AssumeRole"}]}'

aws iam put-role-policy --role-name same_role_name_as_previous \
--policy-name $PREFIX-secret-reader-policy --policy-document """  
same_json_as_in_previous_example  
"""

aws kms create-key --description "$PREFIX-test-key" --policy """
{
    "Id": "$PREFIX-kms-policy",
    "Version": "2012-10-17",
    "Statement":
    [
        {
            "Sid": "Enable IAM User Permissions",
            "Effect": "Allow",
            "Principal": {"AWS": "arn:aws:iam::account_id:root"},
            "Action": "kms:*", "Resource": "*"
        },
        {
            "Sid": "Allow access for Key Administrators",
            "Effect": "Allow",
            "Principal":
            {
                "AWS":
                ["$USER_ARN", "arn:aws:iam::account_id:role/Admin"]
            },
            "Action":
            [
                "kms>Create*",
                "kms>Describe*",
                "kms>Enable*",
                "kms>List*",
                "kms>Put*",
                "kms>Update*",
                "kms>Revoke*",
                "kms>Disable*",
                "kms>Get*",
                "kms>Delete*",
                "kms>TagResource",
                "kms>UntagResource",
                "kms>ScheduleKeyDeletion",
                "kms>CancelKeyDeletion"
            ],
            "Resource": "*"
        },
        {
            "Sid": "Allow use of the key",
            "Effect": "Allow",
            "Principal": {"AWS": "$ROLE_ARN"},
            "Action": ["kms>Decrypt", "kms>DescribeKey"],
            "Resource": "*"
        }
    ]
}
```

```
    }
}
"""
```

## Creating an RDS Proxy

To manage connections for a DB cluster, you can create a proxy. You can associate a proxy with an Aurora MySQL or Aurora PostgreSQL DB cluster.

### AWS Management Console

#### To create a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Choose **Create proxy**.
4. Choose all the settings for your proxy.

For **Proxy configuration**, provide information for the following:

- **Proxy identifier.** Specify a name of your choosing, unique within your AWS account ID and current AWS Region.
- **Engine family.** This setting determines which database network protocol the proxy recognizes when it interprets network traffic to and from the database. For Aurora MySQL, choose **MySQL**. For Aurora PostgreSQL, choose **PostgreSQL**.
- **Require Transport Layer Security.** Choose this setting if you want the proxy to enforce TLS/SSL for all client connections. When you use an encrypted or unencrypted connection to a proxy, the proxy uses the same encryption setting when it makes a connection to the underlying database.
- **Idle client connection timeout.** Choose a time period that a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes). A client connection is considered idle when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections.

Consider lowering the idle client connection timeout if you want the proxy to proactively remove stale connections. If your workload is spiking, consider raising the idle client connection timeout to save the cost of establishing connections.

For **Target group configuration**, provide information for the following:

- **Database.** Choose one RDS DB instance or Aurora DB cluster to access through this proxy. The list only includes DB instances and clusters with compatible database engines, engine versions, and other settings. If the list is empty, create a new DB instance or cluster that's compatible with RDS Proxy. To do so, follow the procedure in [Creating an Amazon Aurora DB cluster \(p. 127\)](#). Then try creating the proxy again.
- **Connection pool maximum connections.** Specify a value from 1 through 100. This setting represents the percentage of the `max_connections` value that RDS Proxy can use for its connections. If you only intend to use one proxy with this DB instance or cluster, you can set this value to 100. For details about how RDS Proxy uses this setting, see [MaxConnectionsPercent \(p. 1454\)](#).
- **Session pinning filters.** (Optional) This is an advanced setting, for troubleshooting performance issues with particular applications. Currently, the setting isn't supported for PostgreSQL and the only choice is `EXCLUDE_VARIABLE_SETS`. Choose a filter only if both of following are true: Your

application isn't reusing connections due to certain kinds of SQL statements, and you can verify that reusing connections with those SQL statements doesn't affect application correctness. For more information, see [Avoiding pinning \(p. 1455\)](#).

- **Connection borrow timeout.** In some cases, you might expect the proxy to sometimes use all available database connections. In such cases, you can specify how long the proxy waits for a database connection to become available before returning a timeout error. You can specify a period up to a maximum of five minutes. This setting only applies when the proxy has the maximum number of connections open and all connections are already in use.
- **Initialization query.** (Optional) You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with `SET` statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single `SET` statement, such as `SET x=1, y=2`. Initialization query is not currently supported for PostgreSQL.

For **Connectivity**, provide information for the following:

- **Secrets Manager secrets.** Choose at least one Secrets Manager secret that contains DB user credentials for the RDS DB instance or Aurora DB cluster that you intend to access with this proxy.
- **IAM role.** Choose an IAM role that has permission to access the Secrets Manager secrets that you chose earlier. You can also choose for the AWS Management Console to create a new IAM role for you and use that.
- **IAM Authentication.** Choose whether to require or disallow IAM authentication for connections to your proxy. The choice of IAM authentication or native database authentication applies to all DB users that access this proxy.
- **Subnets.** This field is prepopulated with all the subnets associated with your VPC. You can remove any subnets that you don't need for this proxy. You must leave at least two subnets.

Provide additional connectivity configuration:

- **VPC security group.** Choose an existing VPC security group. You can also choose for the AWS Management Console to create a new security group for you and use that.

#### Note

This security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group. When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see [Work with shared VPCs](#).

(Optional) Provide advanced configuration:

- **Enable enhanced logging.** You can enable this setting to troubleshoot proxy compatibility or performance issues.

When this setting is enabled, RDS Proxy includes detailed information about SQL statements in its logs. This information helps you to debug issues involving SQL behavior or the performance and scalability of the proxy connections. The debug information includes the text of SQL statements that you submit through the proxy. Thus, only enable this setting when needed for debugging, and only when you have security measures in place to safeguard any sensitive information that appears in the logs.

To minimize overhead associated with your proxy, RDS Proxy automatically turns this setting off 24 hours after you enable it. Enable it temporarily to troubleshoot a specific issue.

5. Choose **Create Proxy**.

## AWS CLI

To create a proxy, use the AWS CLI command [create-db-proxy](#). The `--engine-family` value is case-sensitive.

### Example

For Linux, macOS, or Unix:

```
aws rds create-db-proxy \
    --db-proxy-name proxy_name \
    --engine-family { MYSQL | POSTGRESQL } \
    --auth ProxyAuthenticationConfig_JSON_string \
    --role-arn iam_role \
    --vpc-subnet-ids space_separated_list \
    [--vpc-security-group-ids space_separated_list] \
    [--require-tls | --no-require-tls] \
    [--idle-client-timeout value] \
    [--debug-logging | --no-debug-logging] \
    [--tags comma_separated_list]
```

For Windows:

```
aws rds create-db-proxy ^
    --db-proxy-name proxy_name ^
    --engine-family { MYSQL | POSTGRESQL } ^
    --auth ProxyAuthenticationConfig_JSON_string ^
    --role-arn iam_role ^
    --vpc-subnet-ids space_separated_list ^
    [--vpc-security-group-ids space_separated_list] ^
    [--require-tls | --no-require-tls] ^
    [--idle-client-timeout value] ^
    [--debug-logging | --no-debug-logging] ^
    [--tags comma_separated_list]
```

### Tip

If you don't already know the subnet IDs to use for the `--vpc-subnet-ids` parameter, see [Setting up network prerequisites \(p. 1437\)](#) for examples of how to find the subnet IDs that you can use.

### Note

The security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.

When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see [Work with shared VPCs](#).

To create the required information and associations for the proxy, you also use the [register-db-proxy-targets](#) command. Specify the target group name `default`. RDS Proxy automatically creates a target group with this name when you create each proxy.

```
aws rds register-db-proxy-targets
```

```
--db-proxy-name value
[--target-group-name target_group_name]
[--db-instance-identifiers space-separated_list] # rds db instances, or
[--db-cluster-identifiers cluster_id]           # rds db cluster (all instances), or
[--db-cluster-endpoint endpoint_name]          # rds db cluster endpoint (all
instances)
```

## RDS API

To create an RDS proxy, call the Amazon RDS API operation [CreateDBProxy](#). You pass a parameter with the [AuthConfig](#) data structure.

RDS Proxy automatically creates a target group named `default` when you create each proxy. You associate an RDS DB instance or Aurora DB cluster with the target group by calling the function [RegisterDBProxyTargets](#).

## Viewing an RDS Proxy

After you create one or more RDS proxies, you can view them all to examine their configuration details and choose which ones to modify, delete, and so on.

Any database applications that use the proxy require the proxy endpoint to use in the connection string.

### AWS Management Console

#### To view your proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the RDS Proxy.
3. In the navigation pane, choose **Proxies**.
4. Choose the name of an RDS proxy to display its details.
5. On the details page, the **Target groups** section shows how the proxy is associated with a specific RDS DB instance or Aurora DB cluster. You can follow the link to the **default** target group page to see more details about the association between the proxy and the database. This page is where you see settings that you specified when creating the proxy, such as maximum connection percentage, connection borrow timeout, engine family, and session pinning filters.

### CLI

To view your proxy using the CLI, use the `describe-db-proxies` command. By default, it displays all proxies owned by your AWS account. To see details for a single proxy, specify its name with the `--db-proxy-name` parameter.

```
aws rds describe-db-proxies [--db-proxy-name proxy_name]
```

To view the other information associated with the proxy, use the following commands.

```
aws rds describe-db-proxy-target-groups --db-proxy-name proxy_name
aws rds describe-db-proxy-targets --db-proxy-name proxy_name
```

Use the following sequence of commands to see more detail about the things that are associated with the proxy:

1. To get a list of proxies, run [describe-db-proxies](#).
2. To show connection parameters such as the maximum percentage of connections that the proxy can use, run [describe-db-proxy-target-groups](#) --db-proxy-name and use the name of the proxy as the parameter value.
3. To see the details of the RDS DB instance or Aurora DB cluster associated with the returned target group, run [describe-db-proxy-targets](#).

## RDS API

To view your proxies using the RDS API, use the [DescribeDBProxies](#) operation. It returns values of the [DBProxy](#) data type.

To see details of the connection settings for the proxy, use the proxy identifiers from this return value with the [DescribeDBProxyTargetGroups](#) operation. It returns values of the [DBProxyTargetGroup](#) data type.

To see the RDS instance or Aurora DB cluster associated with the proxy, use the [DescribeDBProxyTargets](#) operation. It returns values of the [DBProxyTarget](#) data type.

## Connecting to a database through RDS Proxy

You connect to an RDS DB instance or Aurora DB cluster through a proxy in generally the same way as you connect directly to the database. The main difference is that you specify the proxy endpoint instead of the instance or cluster endpoint. For an Aurora DB cluster, by default all proxy connections have read/write capability and use the writer instance. If you normally use the reader endpoint for read-only connections, you can create an additional read-only endpoint for the proxy and use that endpoint the same way. For more information, see [Overview of proxy endpoints \(p. 1458\)](#).

### Topics

- [Connecting to a proxy using native authentication \(p. 1446\)](#)
- [Connecting to a proxy using IAM authentication \(p. 1447\)](#)
- [Considerations for connecting to a proxy with PostgreSQL \(p. 1447\)](#)

## Connecting to a proxy using native authentication

Use the following basic steps to connect to a proxy using native authentication:

1. Find the proxy endpoint. In the AWS Management Console, you can find the endpoint on the details page for the corresponding proxy. With the AWS CLI, you can use the [describe-db-proxies](#) command. The following example shows how.

```
# Add --output text to get output as a simple tab-separated list.
$ aws rds describe-db-proxies --query '*[*].{DBProxyName:DBProxyName,Endpoint:Endpoint}'
[
  [
    {
      "Endpoint": "the-proxy.proxy-demo.us-east-1.rds.amazonaws.com",
      "DBProxyName": "the-proxy"
    },
    {
      "Endpoint": "the-proxy-other-secret.proxy-demo.us-east-1.rds.amazonaws.com",
      "DBProxyName": "the-proxy-other-secret"
    },
    {
      "Endpoint": "the-proxy-rds-secret.proxy-demo.us-east-1.rds.amazonaws.com",
      "DBProxyName": "the-proxy-rds-secret"
    }
]
```

```
        },
        {
            "Endpoint": "the-proxy-t3.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-t3"
        }
    ]
}
```

2. Specify that endpoint as the host parameter in the connection string for your client application. For example, specify the proxy endpoint as the value for the `mysql -h` option or `psql -h` option.
3. Supply the same database user name and password as you usually do.

## Connecting to a proxy using IAM authentication

When you use IAM authentication with RDS Proxy, set up your database users to authenticate with regular user names and passwords. The IAM authentication applies to RDS Proxy retrieving the user name and password credentials from Secrets Manager. The connection from RDS Proxy to the underlying database doesn't go through IAM.

To connect to RDS Proxy using IAM authentication, follow the same general procedure as for connecting to an RDS DB instance or Aurora cluster using IAM authentication. For general information about using IAM with RDS and Aurora, see [Security in Amazon Aurora \(p. 1634\)](#).

The major differences in IAM usage for RDS Proxy include the following:

- You don't configure each individual database user with an authorization plugin. The database users still have regular user names and passwords within the database. You set up Secrets Manager secrets containing these user names and passwords, and authorize RDS Proxy to retrieve the credentials from Secrets Manager.

The IAM authentication applies to the connection between your client program and the proxy. The proxy then authenticates to the database using the user name and password credentials retrieved from Secrets Manager.

- Instead of the instance, cluster, or reader endpoint, you specify the proxy endpoint. For details about the proxy endpoint, see [Connecting to your DB cluster using IAM authentication \(p. 1690\)](#).
- In the direct database IAM authentication case, you selectively choose database users and configure them to be identified with a special authentication plugin. You can then connect to those users using IAM authentication.

In the proxy use case, you provide the proxy with Secrets that contain some user's user name and password (native authentication). You then connect to the proxy using IAM authentication. Here, you do this by generating an authentication token with the proxy endpoint, not the database endpoint. You also use a user name that matches one of the user names for the secrets that you provided.

- Make sure that you use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) when connecting to a proxy using IAM authentication.

You can grant a specific user access to the proxy by modifying the IAM policy. An example follows.

```
"Resource": "arn:aws:rds-db:us-east-2:1234567890:dbuser:prx-ABCDEFGHIJKL01234/db_user"
```

## Considerations for connecting to a proxy with PostgreSQL

For PostgreSQL, when a client starts a connection to a PostgreSQL database, it sends a startup message that includes pairs of parameter name and value strings. For details, see the `StartupMessage` in [PostgreSQL message formats](#) in the PostgreSQL documentation.

When connecting through an RDS proxy, the startup message can include the following currently recognized parameters:

- `user`
- `database`
- `replication`

The startup message can also include the following additional runtime parameters:

- `application_name`
- `client_encoding`
- `DateStyle`
- `TimeZone`
- `extra_float_digits`

For more information about PostgreSQL messaging, see the [Frontend/Backend protocol](#) in the PostgreSQL documentation.

For PostgreSQL, if you use JDBC we recommend the following to avoid pinning:

- Set the JDBC connection parameter `assumeMinServerVersion` to at least 9.0 to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET extra_float_digits = 3`.
- Set the JDBC connection parameter `ApplicationName` to `any/your-application-name` to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET application_name = "PostgreSQL JDBC Driver"`. Note the JDBC parameter is `ApplicationName` but the PostgreSQL `StartupMessage` parameter is `application_name`.
- Set the JDBC connection parameter `preferQueryMode` to `extendedForPrepared` to avoid pinning. The `extendedForPrepared` ensures that the extended mode is used only for prepared statements.

The default for the `preferQueryMode` parameter is `extended`, which uses the extended mode for all queries. The extended mode uses a series of `Prepare`, `Bind`, `Execute`, and `Sync` requests and corresponding responses. This type of series causes connection pinning in an RDS proxy.

For more information, see [Avoiding pinning \(p. 1455\)](#). For more information about connecting using JDBC, see [Connecting to the database](#) in the PostgreSQL documentation.

## Managing an RDS Proxy

Following, you can find an explanation of how to manage RDS Proxy operation and configuration. These procedures help your application make the most efficient use of database connections and achieve maximum connection reuse. The more that you can take advantage of connection reuse, the more CPU and memory overhead that you can save. This in turn reduces latency for your application and enables the database to devote more of its resources to processing application requests.

### Topics

- [Modifying an RDS Proxy \(p. 1449\)](#)
- [Adding a new database user \(p. 1453\)](#)
- [Changing the password for a database user \(p. 1453\)](#)
- [Configuring connection settings \(p. 1453\)](#)

- [Avoiding pinning \(p. 1455\)](#)
- [Deleting an RDS Proxy \(p. 1457\)](#)

## Modifying an RDS Proxy

You can change certain settings associated with a proxy after you create the proxy. You do so by modifying the proxy itself, its associated target group, or both. Each proxy has an associated target group.

### AWS Management Console

#### To modify the settings for a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list of proxies, choose the proxy whose settings you want to modify or go to its details page.
4. For **Actions**, choose **Modify**.
5. Enter or choose the properties to modify. You can modify the following:
  - **Proxy identifier** – Rename the proxy by entering a new identifier.
  - **Require Transport Layer Security** – Turn the requirement for Transport layer Security (TLS) on or off.
  - **Idle client connection timeout** – Enter a time period for the idle client connection timeout.
  - **Secrets Manager secrets** – Add or remove Secrets Manager secrets. These secrets correspond to database user names and passwords.
  - **IAM role** – Change the IAM role used to retrieve the secrets from Secrets Manager.
  - **IAM Authentication** – Require or disallow IAM authentication for connections to the proxy.
  - **VPC security group** – Add or remove VPC security groups for the proxy to use.
  - **Enable enhanced logging** – Enable or disable enhanced logging.
6. Choose **Modify**.

If you didn't find the settings listed that you want to change, use the following procedure to update the target group for the proxy. The *target group* associated with a proxy controls the settings related to the physical database connections. Each proxy has one associated target group named `default`, which is created automatically along with the proxy.

You can only modify the target group from the proxy details page, not from the list on the **Proxies** page.

#### To modify the settings for a proxy target group

1. On the **Proxies** page, go to the details page for a proxy.
2. For **Target groups**, choose the `default` link. Currently, all proxies have a single target group named `default`.
3. On the details page for the `default` target group, choose **Modify**.
4. Choose new settings for the properties that you can modify:
  - **Database** – Choose a different RDS DB instance or Aurora cluster.
  - **Connection pool maximum connections** – Adjust what percentage of the maximum available connections the proxy can use.
  - **Session pinning filters** – (Optional) Choose a session pinning filter. Doing this can help reduce performance issues due to insufficient transaction-level reuse for connections. Using this setting

requires understanding of application behavior and the circumstances under which RDS Proxy pins a session to a database connection. Currently, the setting isn't supported for PostgreSQL and the only choice is `EXCLUDE_VARIABLE_SETS`.

- **Connection borrow timeout** – Adjust the connection borrow timeout interval. This setting applies when the maximum number of connections is already being used for the proxy. The setting determines how long the proxy waits for a connection to become available before returning a timeout error.
- **Initialization query** – (Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with `SET` statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single `SET` statement, such as `SET x=1, y=2`. Initialization query is not currently supported for PostgreSQL.

You can't change certain properties, such as the target group identifier and the database engine.

## 5. Choose **Modify target group**.

### AWS CLI

To modify a proxy using the AWS CLI, use the commands [modify-db-proxy](#), [modify-db-proxy-target-group](#), [deregister-db-proxy-targets](#), and [register-db-proxy-targets](#).

With the `modify-db-proxy` command, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

The following example shows how to rename an existing proxy.

```
aws rds modify-db-proxy --db-proxy-name the-proxy --new-db-proxy-name the_new_name
```

To modify connection-related settings or rename the target group, use the `modify-db-proxy-target-group` command. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

The following example shows how to first check the `MaxIdleConnectionsPercent` setting for a proxy and then change it, using the target group.

```
aws rds describe-db-proxy-target-groups --db-proxy-name the-proxy

{
    "TargetGroups": [
        {
            "Status": "available",
            "UpdatedDate": "2019-11-30T16:49:30.342Z",
            "ConnectionPoolConfig": {
                "MaxIdleConnectionsPercent": 50,
                "ConnectionBorrowTimeout": 120,
                "MaxConnectionsPercent": 100,
                "SessionPinningFilters": []
            }
        }
    ]
}
```

```

        },
        "TargetGroupName": "default",
        "CreatedDate": "2019-11-30T16:49:27.940Z",
        "DBProxyName": "the-proxy",
        "IsDefault": true
    }
}

aws rds modify-db-proxy-target-group --db-proxy-name the-proxy --target-group-name default
--connection-pool-config '
{ "MaxIdleConnectionsPercent": 75 }'

{
    "DBProxyTargetGroup": {
        "Status": "available",
        "UpdatedDate": "2019-12-02T04:09:50.420Z",
        "ConnectionPoolConfig": {
            "MaxIdleConnectionsPercent": 75,
            "ConnectionBorrowTimeout": 120,
            "MaxConnectionsPercent": 100,
            "SessionPinningFilters": []
        },
        "TargetGroupName": "default",
        "CreatedDate": "2019-11-30T16:49:27.940Z",
        "DBProxyName": "the-proxy",
        "IsDefault": true
    }
}

```

With the `deregister-db-proxy-targets` and `register-db-proxy-targets` commands, you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration, or all the DB instances in an Aurora cluster.

The following example starts with a proxy that is associated with an Aurora MySQL cluster named `cluster-56-2020-02-25-1399`. The example shows how to change the proxy so that it can connect to a different cluster named `provisioned-cluster`.

When you work with an RDS DB instance, you specify the `--db-instance-identifier` option. When you work with an Aurora DB cluster, you specify the `--db-cluster-identifier` option instead.

The following example modifies an Aurora MySQL proxy. An Aurora PostgreSQL proxy has port 5432.

```

aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": [
        {
            "Endpoint": "instance-9814.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-9814"
        },
        {
            "Endpoint": "instance-8898.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-8898"
        },
        {
            "Endpoint": "instance-1018.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",

```

```

        "Port": 3306,
        "RdsResourceId": "instance-1018"
    },
    {
        "Type": "TRACKED_CLUSTER",
        "Port": 0,
        "RdsResourceId": "cluster-56-2020-02-25-1399"
    },
    {
        "Endpoint": "instance-4330.demo.us-east-1.rds.amazonaws.com",
        "Type": "RDS_INSTANCE",
        "Port": 3306,
        "RdsResourceId": "instance-4330"
    }
]
}

aws rds deregister-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
cluster-56-2020-02-25-1399

aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": []
}

aws rds register-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
provisioned-cluster

{
    "DBProxyTargets": [
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "provisioned-cluster"
        },
        {
            "Endpoint": "gkldje.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "gkldje"
        },
        {
            "Endpoint": "provisioned-1.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "provisioned-1"
        }
    ]
}

```

## RDS API

To modify a proxy using the RDS API, you use the operations [ModifyDBProxy](#), [ModifyDBProxyTargetGroup](#), [DeregisterDBProxyTargets](#), and [RegisterDBProxyTargets](#) operations.

With [ModifyDBProxy](#), you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.

- The security groups used by the proxy.

With `ModifyDBProxyTargetGroup`, you can modify connection-related settings or rename the target group. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

With `DeregisterDBProxyTargets` and `RegisterDBProxyTargets`, you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration, or all the DB instances in an Aurora cluster.

## Adding a new database user

In some cases, you might add a new database user to an RDS DB instance or Aurora cluster that's associated with a proxy. If so, add or repurpose a Secrets Manager secret to store the credentials for that user. To do this, choose one of the following options:

- Create a new Secrets Manager secret, using the procedure described in [Setting up database credentials in AWS Secrets Manager \(p. 1438\)](#).
- Update the IAM role to give RDS Proxy access to the new Secrets Manager secret. To do so, update the resources section of the IAM role policy.
- If the new user takes the place of an existing one, update the credentials stored in the proxy's Secrets Manager secret for the existing user.

## Changing the password for a database user

In some cases, you might change the password for a database user in an RDS DB instance or Aurora cluster that's associated with a proxy. If so, update the corresponding Secrets Manager secret with the new password.

## Configuring connection settings

To adjust RDS Proxy's connection pooling, you can modify the following settings:

- [IdleClientTimeout \(p. 1453\)](#)
- [MaxConnectionsPercent \(p. 1454\)](#)
- [MaxIdleConnectionsPercent \(p. 1454\)](#)
- [ConnectionBorrowTimeout \(p. 1454\)](#)

### IdleClientTimeout

You can specify how long a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes).

A client connection is considered *idle* when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections. If you want the proxy to proactively remove stale connections, consider lowering the idle client connection timeout. If your workload establishes frequent connections with the proxy, consider raising the idle client connection timeout to save the cost of establishing connections.

This setting is represented by the **Idle client connection timeout** field in the RDS console and the `IdleClientTimeout` setting in the AWS CLI and the API. To learn how to change the value of the **Idle**

**client connection timeout** field in the RDS console, see [AWS Management Console \(p. 1449\)](#). To learn how to change the value of the `IdleClientTimeout` setting, see the CLI command [modify-db-proxy](#) or the API operation [ModifyDBProxy](#).

## MaxConnectionsPercent

You can limit the number of connections that an RDS Proxy can establish with the database. You specify the limit as a percentage of the maximum connections available for your database. The proxy doesn't create all of these connections in advance. This setting reserves the right for the proxy to establish these connections as the workload needs them.

For example, suppose that you configured RDS Proxy to use 75 percent of the maximum connections for your database that supports a maximum of 1,000 concurrent connections. In that case, RDS Proxy can open up to 750 database connections.

This setting is represented by the **Connection pool maximum connections** field in the RDS console and the `MaxConnectionsPercent` setting in the AWS CLI and the API. To learn how to change the value of the **Connection pool maximum connections** field in the RDS console, see [AWS Management Console \(p. 1449\)](#). To learn how to change the value of the `MaxConnectionsPercent` setting, see the CLI command [modify-db-proxy-target-group](#) or the API operation [ModifyDBProxyTargetGroup](#).

For information on database connection limits, see [Maximum connections to an Aurora MySQL DB instance](#) and [Maximum connections to an Aurora PostgreSQL DB instance](#).

## MaxIdleConnectionsPercent

You can control the number of idle database connections that RDS Proxy can keep in the connection pool. RDS Proxy considers a database connection in its pool to be *idle* when there's been no activity on the connection for five minutes.

You specify the limit as a percentage of the maximum connections available for your database. The default value is 50 percent and the upper limit is the value of `MaxConnectionsPercent`. With a high value, the proxy leaves a high percentage of idle database connections open. With a low value, the proxy closes a high percentage of idle database connections. If your workloads are unpredictable, consider setting a high value for `MaxIdleConnectionsPercent` so that RDS Proxy can accommodate surges in activity without opening a lot of new database connections.

This setting is represented by the `MaxIdleConnectionsPercent` setting of `DBProxyTargetGroup` in the AWS CLI and the API. To learn how to change the value of the `MaxIdleConnectionsPercent` setting, see the CLI command [modify-db-proxy-target-group](#) or the API operation [ModifyDBProxyTargetGroup](#).

### Note

RDS Proxy closes database connections some time after 24 hours when they are no longer in use. The proxy performs this action regardless of the value of the maximum idle connections setting.

For information on database connection limits, see [Maximum connections to an Aurora MySQL DB instance](#) and [Maximum connections to an Aurora PostgreSQL DB instance](#).

## ConnectionBorrowTimeout

You can choose how long RDS Proxy waits for a database connection in the connection pool to become available for use before returning a timeout error. The default is 120 seconds. This setting applies when the number of connections is at the maximum, and so no connections are available in the connection pool. It also applies if no appropriate database instance is available to handle the request because, for example, a failover operation is in process. Using this setting, you can set the best wait period for your application without having to change the query timeout in your application code.

This setting is represented by the **Connection borrow timeout** field in the RDS console or the `ConnectionBorrowTimeout` setting of `DBProxyTargetGroup` in the AWS CLI or API. To learn how to change the value of the **Connection borrow timeout** field in the RDS console, see [AWS Management Console \(p. 1449\)](#). To learn how to change the value of the `ConnectionBorrowTimeout` setting, see the CLI command [modify-db-proxy-target-group](#) or the API operation [ModifyDBProxyTargetGroup](#).

## Avoiding pinning

Multiplexing is more efficient when database requests don't rely on state information from previous requests. In that case, RDS Proxy can reuse a connection at the conclusion of each transaction. Examples of such state information include most variables and configuration parameters that you can change through `SET` or `SELECT` statements. SQL transactions on a client connection can multiplex between underlying database connections by default.

Your connections to the proxy can enter a state known as *pinning*. When a connection is pinned, each later transaction uses the same underlying database connection until the session ends. Other client connections also can't reuse that database connection until the session ends. The session ends when the client connection is dropped.

RDS Proxy automatically pins a client connection to a specific DB connection when it detects a session state change that isn't appropriate for other sessions. Pinning reduces the effectiveness of connection reuse. If all or almost all of your connections experience pinning, consider modifying your application code or workload to reduce the conditions that cause the pinning.

For example, if your application changes a session variable or configuration parameter, later statements can rely on the new variable or parameter to be in effect. Thus, when RDS Proxy processes requests to change session variables or configuration settings, it pins that session to the DB connection. That way, the session state remains in effect for all later transactions in the same session.

For MySQL engine family databases, this rule doesn't apply to all parameters that you can set. RDS Proxy tracks certain statements and variables. Thus RDS Proxy doesn't pin the session when you modify them. In this case, RDS Proxy only reuses the connection for other sessions that have the same values for those settings.

Following are the MySQL statements that RDS Proxy tracks:

- `DROP DATABASE`
- `DROP SCHEMA`
- `USE`

Following are the MySQL variables that RDS Proxy tracks:

- `AUTOCOMMIT`
- `AUTO_INCREMENT_INCREMENT`
- `CHARACTER SET` (or `CHAR SET`)
- `CHARACTER_SET_CLIENT`
- `CHARACTER_SET_DATABASE`
- `CHARACTER_SET_FILESYSTEM`
- `CHARACTER_SET_CONNECTION`
- `CHARACTER_SET_RESULTS`
- `CHARACTER_SET_SERVER`
- `COLLATION_CONNECTION`
- `COLLATION_DATABASE`

- `COLLATION_SERVER`
- `INTERACTIVE_TIMEOUT`
- `NAMES`
- `NET_WRITE_TIMEOUT`
- `QUERY_CACHE_TYPE`
- `SESSION_TRACK_SCHEMA`
- `SQL_MODE`
- `TIME_ZONE`
- `TRANSACTION_ISOLATION` (or `TX_ISOLATION`)
- `TRANSACTION_READ_ONLY` (or `TX_READ_ONLY`)
- `WAIT_TIMEOUT`

Performance tuning for RDS Proxy involves trying to maximize transaction-level connection reuse (multiplexing) by minimizing pinning. You can do so by doing the following:

- Avoid unnecessary database requests that might cause pinning.
- Set variables and configuration settings consistently across all connections. That way, later sessions are more likely to reuse connections that have those particular settings.

However, for PostgreSQL setting a variable leads to session pinning.

- For a MySQL engine family database, apply a session pinning filter to the proxy. You can exempt certain kinds of operations from pinning the session if you know that doing so doesn't affect the correct operation of your application.
- See how frequently pinning occurs by monitoring the CloudWatch metric `DatabaseConnectionsCurrentlySessionPinned`. For information about this and other CloudWatch metrics, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 1467\)](#).
- If you use `SET` statements to perform identical initialization for each client connection, you can do so while preserving transaction-level multiplexing. In this case, you move the statements that set up the initial session state into the initialization query used by a proxy. This property is a string containing one or more SQL statements, separated by semicolons.

For example, you can define an initialization query for a proxy that sets certain configuration parameters. Then, RDS Proxy applies those settings whenever it sets up a new connection for that proxy. You can remove the corresponding `SET` statements from your application code, so that they don't interfere with transaction-level multiplexing.

For metrics about how often pinning occurs for a proxy, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 1467\)](#).

## Conditions that cause pinning for all engine families

The proxy pins the session to the current connection in the following situations where multiplexing might cause unexpected behavior:

- Any statement with a text size greater than 16 KB causes the proxy to pin the session.
- Prepared statements cause the proxy to pin the session. This rule applies whether the prepared statement uses SQL text or the binary protocol.

## Conditions that cause pinning for MySQL

For MySQL, the following interactions also cause pinning:

- Explicit table lock statements `LOCK TABLE`, `LOCK TABLES`, or `FLUSH TABLES WITH READ LOCK` cause the proxy to pin the session.
- Creating named locks by using `GET_LOCK` causes the proxy to pin the session.
- Setting a user variable or a system variable (with some exceptions) causes the proxy to pin the session. If this situation reduces your connection reuse too much, you can choose for `SET` operations not to cause pinning. For information about how to do so by setting the session pinning filters property, see [Creating an RDS Proxy \(p. 1442\)](#) and [Modifying an RDS Proxy \(p. 1449\)](#).
- Creating a temporary table causes the proxy to pin the session. That way, the contents of the temporary table are preserved throughout the session regardless of transaction boundaries.
- Calling the functions `ROW_COUNT`, `FOUND_ROWS`, and `LAST_INSERT_ID` sometimes causes pinning.

The exact circumstances where these functions cause pinning might differ between Aurora MySQL versions that are compatible with MySQL 5.6 and MySQL 5.7.

Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Therefore, make sure that your application doesn't change session state inside stored routines and rely on that session state to persist across transactions. For example, if a stored procedure creates a temporary table that is intended to persist across transactions, that application currently isn't compatible with RDS Proxy.

If you have expert knowledge about your application behavior, you can skip the pinning behavior for certain application statements. To do so, choose the **Session pinning filters** option when creating the proxy. Currently, you can opt out of session pinning for setting session variables and configuration settings.

## Conditions that cause pinning for PostgreSQL

For PostgreSQL, the following interactions also cause pinning:

- Using `SET` commands
- Using the PostgreSQL extended query protocol such as by using JDBC default settings
- Creating temporary sequences, tables, or views
- Declaring cursors
- Discarding the session state
- Listening on a notification channel
- Loading a library module such as `auto_explain`
- Manipulating sequences using functions such as `nextval` and `setval`
- Interacting with locks using functions such as `pg_advisory_lock` and `pg_try_advisory_lock`
- Using prepared statements, setting parameters, or resetting a parameter to its default

## Deleting an RDS Proxy

You can delete a proxy if you no longer need it. You might delete a proxy because the application that was using it is no longer relevant. Or you might delete a proxy if you take the DB instance or cluster associated with it out of service.

### AWS Management Console

#### To delete a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Proxies**.
3. Choose the proxy to delete from the list.
4. Choose **Delete Proxy**.

## AWS CLI

To delete a DB proxy, use the AWS CLI command [delete-db-proxy](#). To remove related associations, also use the [deregister-db-proxy-targets](#) command.

```
aws rds delete-db-proxy --name proxy_name
```

```
aws rds deregister-db-proxy-targets
  --db-proxy-name proxy_name
  [--target-group-name target_group_name]
  [--target-ids comma_separated_list]      # or
  [--db-instance-identifiers instance_id]      # or
  [--db-cluster-identifiers cluster_id]
```

## RDS API

To delete a DB proxy, call the Amazon RDS API function [DeleteDBProxy](#). To delete related items and associations, you also call the functions [DeleteDBProxyTargetGroup](#) and [DeregisterDBProxyTargets](#).

# Working with Amazon RDS Proxy endpoints

Following, you can learn about endpoints for RDS Proxy and how to use them. By using endpoints, you can take advantage of the following capabilities:

- You can use multiple endpoints with a proxy to monitor and troubleshoot connections from different applications independently.
- You can use reader endpoints with Aurora DB clusters to improve read scalability and high availability for your query-intensive applications.
- You can use a cross-VPC endpoint to allow access to databases in one VPC from resources such as Amazon EC2 instances in a different VPC.

### Topics

- [Limitations for proxy endpoints \(p. 1467\)](#)

## Overview of proxy endpoints

Working with RDS Proxy endpoints involves the same kinds of procedures as with Aurora DB cluster and reader endpoints and RDS instance endpoints. If you aren't familiar with Aurora endpoints, find more information in [Amazon Aurora connection management \(p. 35\)](#).

By default, the endpoint that you connect to when you use RDS Proxy with an Aurora cluster has read/write capability. As a consequence, this endpoint sends all requests to the writer instance of the cluster, and all of those connections count against the `max_connections` value for the writer instance. If your proxy is associated with an Aurora DB cluster, you can create additional read/write or read-only endpoints for that proxy.

You can use a read-only endpoint with your proxy for read-only queries, the same way that you use the reader endpoint for an Aurora provisioned cluster. Doing so helps you to take advantage of the read scalability of an Aurora cluster with one or more reader DB instances. You can run more simultaneous queries and make more simultaneous connections by using a read-only endpoint and adding more reader DB instances to your Aurora cluster as needed.

**Tip**

When you create a proxy for an Aurora cluster using the AWS Management Console, you can choose for RDS Proxy to automatically create a reader endpoint. For information about the benefits of a reader endpoint, see [Using reader endpoints with Aurora clusters \(p. 1459\)](#).

For a proxy endpoint that you create, you can also associate the endpoint with a different virtual private cloud (VPC) than the proxy itself uses. By doing so, you can connect to the proxy from a different VPC, for example a VPC used by a different application within your organization.

For information about limits associated with proxy endpoints, see [Limitations for proxy endpoints \(p. 1467\)](#).

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for read/write requests using the default endpoint of a proxy.

Each proxy endpoint has its own set of CloudWatch metrics. You can monitor the metrics for all endpoints of a proxy. You can also monitor metrics for a specific endpoint, or for all the read/write or read-only endpoints of a proxy. For more information, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 1467\)](#).

A proxy endpoint uses the same authentication mechanism as its associated proxy. RDS Proxy automatically sets up permissions and authorizations for the user-defined endpoint, consistent with the properties of the associated proxy.

## Using reader endpoints with Aurora clusters

You can create and connect to read-only endpoints called *reader endpoints* when you use RDS Proxy with Aurora clusters. These reader endpoints help to improve the read scalability of your query-intensive applications. Reader endpoints also help to improve the availability of your connections if a reader DB instance in your cluster becomes unavailable.

**Note**

When you specify that a new endpoint is read-only, RDS Proxy requires that the Aurora cluster has one or more reader DB instances. If you change the target of the proxy to an Aurora cluster containing only a single writer or a multi-writer Aurora cluster, any requests to the reader endpoint fail with an error. Requests also fail if the target of the proxy is an RDS instance instead of an Aurora cluster.

If an Aurora cluster has reader instances but those instances aren't available, RDS Proxy waits to send the request instead of returning an error immediately. If no reader instance becomes available within the connection borrow timeout period, the request fails with an error.

## How reader endpoints help application availability

In some cases, one or more reader instances in your cluster might become unavailable. If so, connections that use a reader endpoint of a DB proxy can recover more quickly than ones that use the Aurora reader endpoint. RDS Proxy routes connections to only the available reader instances in the cluster. There isn't a delay due to DNS caching when an instance becomes unavailable.

If the connection is multiplexed, RDS Proxy directs subsequent queries to a different reader DB instance without any interruption to your application. During the automatic switchover to a new reader instance, RDS Proxy checks the replication lag of the old and new reader instances. RDS Proxy makes sure that the new reader instance is up to date with the same changes as the previous reader instance. That way, your application never sees stale data when RDS Proxy switches from one reader DB instance to another.

If the connection is pinned, the next query on the connection returns an error. However, your application can immediately reconnect to the same endpoint. RDS Proxy routes the connection to a different reader DB instance that's in available state. When you manually reconnect, RDS Proxy doesn't check the replication lag between the old and new reader instances.

If your Aurora cluster doesn't have any available reader instances, RDS Proxy checks whether this condition is temporary or permanent. The behavior in each case is as follows:

- Suppose that your cluster has one or more reader DB instances, but none of them are in the Available state. For example, all reader instances might be rebooting or encountering problems. In that case, attempts to connect to a reader endpoint wait for a reader instance to become available. If no reader instance becomes available within the connection borrow timeout period, the connection attempt fails. If a reader instance does become available, the connection attempt succeeds.
- Suppose that your cluster has no reader DB instances. In that case, RDS Proxy returns an error immediately if you try to connect to a reader endpoint. To resolve this problem, add one or more reader instances to your cluster before you connect to the reader endpoint.

## How reader endpoints help query scalability

Reader endpoints for a proxy help with Aurora query scalability in the following ways:

- As you add reader instances to your Aurora cluster, RDS Proxy can route new connections to any reader endpoints to the different reader instances. That way, queries performed using one reader endpoint connection don't slow down queries performed using another reader endpoint connection. The queries run on separate DB instances. Each DB instance has its own compute resources, buffer cache, and so on.
- Where practical, RDS Proxy uses the same reader DB instance for all the queries issued using a particular reader endpoint connection. That way, a set of related queries on the same tables can take advantage of caching, plan optimization, and so on, on a particular DB instance.
- If a reader DB instance becomes unavailable, the effect on your application depends on whether the session is multiplexed or pinned. If the session is multiplexed, RDS Proxy routes any subsequent queries to a different reader DB instance without any action on your part. If the session is pinned, your application gets an error and must reconnect. You can reconnect to the reader endpoint immediately and RDS Proxy routes the connection to an available reader DB instance. For more information about multiplexing and pinning for proxy sessions, see [Overview of RDS Proxy concepts \(p. 1433\)](#).
- The more reader DB instances you have in the cluster, the more simultaneous connections you can make using reader endpoints. For example, suppose that your cluster has four reader DB instances, each configured to allow 200 simultaneous connections. Suppose that your proxy is configured to use 50% of the maximum connections. Here, the maximum number of connections that you can make through the reader endpoints in the proxy is 100 (50% of 200) for reader 1. It's also 100 for reader 2, and so on, for a total of 400. If you double the number of reader DB instances in the cluster to eight, the maximum number of connections through the reader endpoints also doubles to 800.

## Examples of using reader endpoints

The following Linux example shows how you can confirm that you're connected to an Aurora MySQL cluster through a reader endpoint. The `innodb_read_only` configuration setting is enabled. Attempts to perform write operations such as `CREATE DATABASE` statements fail with an error. And you can

confirm that you're connected to a reader DB instance by checking the DB instance name using the `aurora_server_id` variable.

**Tip**

Don't rely only on checking the DB instance name to determine whether the connection is read/write or read-only. Remember that DB instances in an Aurora cluster can change roles between writer and reader when failovers happen.

```
$ mysql -h endpoint-demo-reader.endpoint.proxy-demo.us-east-1.rds.amazonaws.com -u admin -p
...
mysql> select @@innodb_read_only;
+-----+
| @@innodb_read_only |
+-----+
| 1 |
+-----+
mysql> create database shouldnt_work;
ERROR 1290 (HY000): The MySQL server is running with the --read-only option so it cannot
execute this statement

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id           |
+-----+
| proxy-reader-endpoint-demo-instance-3 |
+-----+
```

The following example shows how your connection to a proxy reader endpoint can keep working even when the reader DB instance is deleted. In this example, the Aurora cluster has two reader instances, `instance-5507` and `instance-7448`. The connection to the reader endpoint begins using one of the reader instances. During the example, this reader instance is deleted by a `delete-db-instance` command. RDS Proxy switches to a different reader instance for subsequent queries.

```
$ mysql -h reader-demo.endpoint.proxy-demo.us-east-1.rds.amazonaws.com
-u my_user -p
...
mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-5507      |
+-----+

mysql> select @@innodb_read_only;
+-----+
| @@innodb_read_only |
+-----+
| 1 |
+-----+

mysql> select count(*) from information_schema.tables;
+-----+
| count(*) |
+-----+
| 328     |
+-----+
```

While the `mysql` session is still running, the following command deletes the reader instance that the reader endpoint is connected to.

```
aws rds delete-db-instance --db-instance-identifier instance-5507 --skip-final-snapshot
```

Queries in the mysql session continue working without the need to reconnect. RDS Proxy automatically switches to a different reader DB instance.

```
mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-7448 |
+-----+

mysql> select count(*) from information_schema.TABLES;
+-----+
| count(*) |
+-----+
|      328 |
+-----+
```

## Accessing Aurora and RDS databases across VPCs

By default, the components of your RDS and Aurora technology stack are all in the same Amazon VPC. For example, suppose that an application running on an Amazon EC2 instance connects to an Amazon RDS DB instance or an Aurora DB cluster. In this case, the application server and database must both be within the same VPC.

With RDS Proxy, you can set up access to an Aurora cluster or RDS instance in one VPC from resources such as EC2 instances in another VPC. For example, your organization might have multiple applications that access the same database resources. Each application might be in its own VPC.

To enable cross-VPC access, you create a new endpoint for the proxy. If you aren't familiar with creating proxy endpoints, see [Working with Amazon RDS Proxy endpoints \(p. 1458\)](#) for details. The proxy itself resides in the same VPC as the Aurora DB cluster or RDS instance. However, the cross-VPC endpoint resides in the other VPC, along with the other resources such as the EC2 instances. The cross-VPC endpoint is associated with subnets and security groups from the same VPC as the EC2 and other resources. These associations let you connect to the endpoint from the applications that otherwise can't access the database due to the VPC restrictions.

The following steps explain how to create and access a cross-VPC endpoint through RDS Proxy:

1. Create two VPCs, or choose two VPCs that you already use for Aurora and RDS work. Each VPC should have its own associated network resources such as an Internet gateway, route tables, subnets, and security groups. If you only have one VPC, you can consult [Getting started with Amazon Aurora \(p. 93\)](#) for the steps to set up another VPC to use Aurora successfully. You can also examine your existing VPC in the Amazon EC2 console to see what kinds of resources to connect together.
2. Create a DB proxy associated with the Aurora DB cluster or RDS instance that you want to connect to. Follow the procedure in [Creating an RDS Proxy \(p. 1442\)](#).
3. On the **Details** page for your proxy in the RDS console, under the **Proxy endpoints** section, choose **Create endpoint**. Follow the procedure in [Creating a proxy endpoint \(p. 1463\)](#).
4. Choose whether to make the cross-VPC endpoint read/write or read-only.
5. Instead of accepting the default of the same VPC as the Aurora DB cluster or RDS instance, choose a different VPC. This VPC must be in the same AWS Region as the VPC where the proxy resides.
6. Now instead of accepting the defaults for subnets and security groups from the same VPC as the Aurora DB cluster or RDS instance, make new selections. Make these based on the subnets and security groups from the VPC that you chose.
7. You don't need to change any of the settings for the Secrets Manager secrets. The same credentials work for all endpoints for your proxy, regardless of which VPC each endpoint is in.
8. Wait for the new endpoint to reach the **Available** state.

9. Make a note of the full endpoint name. This is the value ending in `Region_name.rds.amazonaws.com` that you supply as part of the connection string for your database application.
- 10 Access the new endpoint from a resource in the same VPC as the endpoint. A simple way to test this process is to create a new EC2 instance in this VPC. Then you can log into the EC2 instance and run the `mysql` or `psql` commands to connect by using the endpoint value in your connection string.

## Creating a proxy endpoint

### Console

#### To create a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Click the name of the proxy that you want to create a new endpoint for.

The details page for that proxy appears.

4. In the **Proxy endpoints** section, choose **Create proxy endpoint**.
- The **Create proxy endpoint** window appears.
5. For **Proxy endpoint name**, enter a descriptive name of your choice.
  6. For **Target role**, choose whether to make the endpoint read/write or read-only.

Connections that use a read/write endpoint can perform any kind of operation: data definition language (DDL) statements, data manipulation language (DML) statements, and queries. These endpoints always connect to the primary instance of the Aurora cluster. You can use read/write endpoints for general database operations when you only use a single endpoint in your application. You can also use read/write endpoints for administrative operations, online transaction processing (OLTP) applications, and extract-transform-load (ETL) jobs.

Connections that use a read-only endpoint can only perform queries. When there are multiple reader instances in the Aurora cluster, RDS Proxy can use a different reader instance for each connection to the endpoint. That way, a query-intensive application can take advantage of Aurora's clustering capability. You can add more query capacity to the cluster by adding more reader DB instances. These read-only connections don't impose any overhead on the primary instance of the cluster. That way, your reporting and analysis queries don't slow down the write operations of your OLTP applications.

7. For **Virtual Private Cloud (VPC)**, choose the default if you plan to access the endpoint from the same EC2 instances or other resources where you normally access the proxy or its associated database. If you want to set up cross-VPC access for this proxy, choose a VPC other than the default. For more information about cross-VPC access, see [Accessing Aurora and RDS databases across VPCs \(p. 1462\)](#).
8. For **Subnets**, RDS Proxy fills in the same subnets as the associated proxy by default. If you want to restrict access to the endpoint so that only a portion of the address range of the VPC can connect to it, remove one or more subnets from the set of choices.
9. For **VPC security group**, you can choose an existing security group or create a new one. RDS Proxy fills in the same security group or groups as the associated proxy by default. If the inbound and outbound rules for the proxy are appropriate for this endpoint, you can leave the default choice.

If you choose to create a new security group, specify a name for the security group on this page. Then edit the security group settings from the EC2 console afterward.

10. Choose **Create proxy endpoint**.

## AWS CLI

To create a proxy endpoint, use the AWS CLI [create-db-proxy-endpoint](#) command.

Include the following required parameters:

- `--db-proxy-name value`
- `--db-proxy-endpoint-name value`
- `--vpc-subnet-ids list_of_ids`. Separate the subnet IDs with spaces. You don't specify the ID of the VPC itself.

You can also include the following optional parameters:

- `--target-role { READ_WRITE | READ_ONLY }`. This parameter defaults to `READ_WRITE`. The `READ_ONLY` value only has an effect on Aurora provisioned clusters that contain one or more reader DB instances. When the proxy is associated with an RDS instance or with an Aurora cluster that only contains a writer DB instance, you can't specify `READ_ONLY`. For more information about the intended use of read-only endpoints with Aurora clusters, see [Using reader endpoints with Aurora clusters \(p. 1459\)](#).
- `--vpc-security-group-ids value`. Separate the security group IDs with spaces. If you omit this parameter, RDS Proxy uses the default security group for the VPC. RDS Proxy determines the VPC based on the subnet IDs that you specify for the `--vpc-subnet-ids` parameter.

### Example

The following example creates a proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds create-db-proxy-endpoint \
--db-proxy-name my-proxy \
--db-proxy-endpoint-name my-endpoint \
--vpc-subnet-ids subnet_id subnet_id subnet_id ... \
--target-role READ_ONLY \
--vpc-security-group-ids security_group_id ]
```

For Windows:

```
aws rds create-db-proxy-endpoint ^
--db-proxy-name my-proxy ^
--db-proxy-endpoint-name my-endpoint ^
--vpc-subnet-ids subnet_id_1 subnet_id_2 subnet_id_3 ... ^
--target-role READ_ONLY ^
--vpc-security-group-ids security_group_id
```

## RDS API

To create a proxy endpoint, use the RDS API [CreateProxyEndpoint](#) action.

## Viewing proxy endpoints

## Console

### To view the details for a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to view. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to view. Click its name to view the details page.
5. Examine the parameters whose values you're interested in. You can check properties such as the following:
  - Whether the endpoint is read/write or read-only.
  - The endpoint address that you use in a database connection string.
  - The VPC, subnets, and security groups associated with the endpoint.

## AWS CLI

To view one or more DB proxy endpoints, use the AWS CLI [describe-db-proxy-endpoints](#) command.

You can include the following optional parameters:

- `--db-proxy-endpoint-name`
- `--db-proxy-name`

The following example describes the `my-endpoint` proxy endpoint.

### Example

For Linux, macOS, or Unix:

```
aws rds describe-db-proxy-endpoints \
--db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds describe-db-proxy-endpoints ^
--db-proxy-endpoint-name my-endpoint
```

## RDS API

To describe one or more proxy endpoints, use the RDS API [DescribeDBProxyEndpoints](#) operation.

## Modifying a proxy endpoint

## Console

### To modify one or more proxy endpoints

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to modify. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to modify. You can select it in the list, or click its name to view the details page.
5. On the proxy details page, under the **Proxy endpoints** section, choose **Edit**. Or on the proxy endpoint details page, for **Actions**, choose **Edit**.
6. Change the values of the parameters that you want to modify.
7. Choose **Save changes**.

## AWS CLI

To modify a DB proxy endpoint, use the AWS CLI [modify-db-proxy-endpoint](#) command with the following required parameters:

- `--db-proxy-endpoint-name`

Specify changes to the endpoint properties by using one or more of the following parameters:

- `--new-db-proxy-endpoint-name`
- `--vpc-security-group-ids`. Separate the security group IDs with spaces.

The following example renames the `my-endpoint` proxy endpoint to `new-endpoint-name`.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-proxy-endpoint \
--db-proxy-endpoint-name my-endpoint \
--new-db-proxy-endpoint-name new-endpoint-name
```

For Windows:

```
aws rds modify-db-proxy-endpoint ^
--db-proxy-endpoint-name my-endpoint ^
--new-db-proxy-endpoint-name new-endpoint-name
```

## RDS API

To modify a proxy endpoint, use the RDS API [ModifyDBProxyEndpoint](#) operation.

## Deleting a proxy endpoint

You can delete an endpoint for your proxy using the console as described following.

### Note

You can't delete the default endpoint that RDS Proxy automatically creates for each proxy. When you delete a proxy, RDS Proxy automatically deletes all the associated endpoints.

## Console

### To delete a proxy endpoint using the AWS Management Console

1. In the navigation pane, choose **Proxies**.

2. In the list, choose the proxy whose endpoint you want to endpoint. Click the proxy name to view its details page.
3. In the **Proxy endpoints** section, choose the endpoint that you want to delete. You can select one or more endpoints in the list, or click the name of a single endpoint to view the details page.
4. On the proxy details page, under the **Proxy endpoints** section, choose **Delete**. Or on the proxy endpoint details page, for **Actions**, choose **Delete**.

## AWS CLI

To delete a proxy endpoint, run the [delete-db-proxy-endpoint](#) command with the following required parameters:

- `--db-proxy-endpoint-name`

The following command deletes the proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds delete-db-proxy-endpoint \
--db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds delete-db-proxy-endpoint ^
--db-proxy-endpoint-name my-endpoint
```

## RDS API

To delete a proxy endpoint with the RDS API, run the [DeleteDBProxyEndpoint](#) operation. Specify the name of the proxy endpoint for the `DBProxyEndpointName` parameter.

## Limitations for proxy endpoints

Each proxy has a default endpoint that you can modify but not create or delete.

The maximum number of user-defined endpoints for a proxy is 20. Thus, a proxy can have up to 21 endpoints: the default endpoint, plus 20 that you create.

When you associate additional endpoints with a proxy, RDS Proxy automatically determines which DB instances in your cluster to use for each endpoint. You can't choose specific instances the way that you can with Aurora custom endpoints.

Reader endpoints aren't available for Aurora multi-writer clusters.

## Monitoring RDS Proxy metrics with Amazon CloudWatch

You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console, choose **Metrics**, then choose **RDS**, and choose **Per-Proxy Metrics**. For more information, see [Using Amazon CloudWatch metrics](#) in the Amazon CloudWatch User Guide.

### Note

RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy.

A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to aggregate the values for a proxy across all the associated instances.

Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for read/write requests using the default endpoint of a proxy.

All RDS Proxy metrics are in the group `proxy`.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint independently. For more information about proxy endpoints, see [Working with Amazon RDS Proxy endpoints \(p. 1458\)](#).

You can aggregate the values for each metric using one of the following dimension sets. For example, by using the `ProxyName` dimension set, you can analyze all the traffic for a particular proxy. By using the other dimension sets, you can split the metrics in different ways. You can split the metrics based on the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each database.

- Dimension set 1: `ProxyName`
- Dimension set 2: `ProxyName, EndpointName`
- Dimension set 3: `ProxyName, TargetGroup, Target`
- Dimension set 4: `ProxyName, TargetGroup, TargetRole`

Metric	Description	Valid period	CloudWatch dimension set
<code>AvailabilityPercentage</code>	The percentage of time for which the target group was available in the role indicated by the dimension. This metric is reported every minute. The most useful statistic for this metric is <code>Average</code> .	1 minute	<a href="#">Dimension set 4 (p. 1468)</a>
<code>ClientConnections</code>	The current number of client connections. This metric is reported every minute. The most useful statistic for this metric is <code>Sum</code> .	1 minute	<a href="#">Dimension set 1 (p. 1468), Dimension set 2 (p. 1468)</a>
<code>ClientConnectionsClosed</code>	The number of client connections closed. The most useful statistic for this metric is <code>Sum</code> .	1 minute and above	<a href="#">Dimension set 1 (p. 1468), Dimension set 2 (p. 1468)</a>
<code>ClientConnectionsNoTLS</code>	The current number of client connections without Transport Layer Security (TLS). This metric is reported	1 minute and above	<a href="#">Dimension set 1 (p. 1468), Dimension set 2 (p. 1468)</a>

Metric	Description	Valid period	CloudWatch dimension set
	every minute. The most useful statistic for this metric is Sum.		
ClientConnectionsReceived	The number of client connection requests received. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 1468), Dimension set 2 (p. 1468)
ClientConnectionsSetFailed	The number of client connection attempts that failed due to misconfigured authentication or TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 1468), Dimension set 2 (p. 1468)
ClientConnectionsSetEstablished	The number of client connections successfully established with any authentication mechanism with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 1468), Dimension set 2 (p. 1468)
ClientConnectionsTLS	The current number of client connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 1468), Dimension set 2 (p. 1468)
DatabaseConnectionRequests	The number of requests to create a database connection. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 1468), Dimension set 3 (p. 1468), Dimension set 4 (p. 1468)
DatabaseConnectionRequestsTLS	The number of requests to create a database connection with TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 1468), Dimension set 3 (p. 1468), Dimension set 4 (p. 1468)
DatabaseConnections	The current number of database connections. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 1468), Dimension set 3 (p. 1468), Dimension set 4 (p. 1468)

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsTimeToFirstConnection	The time in microseconds that it takes for the proxy being monitored to get a database connection. The most useful statistic for this metric is Average.	1 minute and above	<a href="#">Dimension set 1 (p. 1468)</a> , <a href="#">Dimension set 2 (p. 1468)</a>
DatabaseConnectionsCurrentBorrowed	The current number of database connections in the borrow state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1 (p. 1468)</a> , <a href="#">Dimension set 3 (p. 1468)</a> , <a href="#">Dimension set 4 (p. 1468)</a>
DatabaseConnectionsCurrentInTransaction	The current number of database connections in a transaction. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1 (p. 1468)</a> , <a href="#">Dimension set 3 (p. 1468)</a> , <a href="#">Dimension set 4 (p. 1468)</a>
DatabaseConnectionsCurrentPinned	The current number of database connections currently pinned because of operations in client requests that change session state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1 (p. 1468)</a> , <a href="#">Dimension set 3 (p. 1468)</a> , <a href="#">Dimension set 4 (p. 1468)</a>
DatabaseConnectionsFailed	The number of database connection requests that failed. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1 (p. 1468)</a> , <a href="#">Dimension set 3 (p. 1468)</a> , <a href="#">Dimension set 4 (p. 1468)</a>
DatabaseConnectionsSuccessful	The number of database connections successfully established with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1 (p. 1468)</a> , <a href="#">Dimension set 3 (p. 1468)</a> , <a href="#">Dimension set 4 (p. 1468)</a>

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsTLS	The current number of database connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 1468), Dimension set 3 (p. 1468), Dimension set 4 (p. 1468)
MaxDatabaseConnections	The maximum number of database connections allowed. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 1468), Dimension set 3 (p. 1468), Dimension set 4 (p. 1468)
QueryDatabaseResponseTime	The time in microseconds that the database took to respond to the query. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1 (p. 1468), Dimension set 2 (p. 1468), Dimension set 3 (p. 1468), Dimension set 4 (p. 1468)
QueryRequests	The number of queries received. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 1468), Dimension set 2 (p. 1468)
QueryRequestsNoTLS	The number of queries received from non-TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 1468), Dimension set 2 (p. 1468)
QueryRequestsTLS	The number of queries received from TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 1468), Dimension set 2 (p. 1468)

Metric	Description	Valid period	CloudWatch dimension set
QueryResponseLatency	The time in microseconds between getting a query request and the proxy responding to it. The most useful statistic for this metric is Average.	1 minute and above	<a href="#">Dimension set 1 (p. 1468)</a> , <a href="#">Dimension set 2 (p. 1468)</a>

You can find logs of RDS Proxy activity under CloudWatch in the AWS Management Console. Each proxy has an entry in the **Log groups** page.

**Important**

These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change. In particular, older logs don't contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name `default` for requests using the default endpoint of a proxy.

## Working with RDS Proxy events

An *event* indicates a change in an environment. This can be an AWS environment or a service or application from a software as a service (SaaS) partner. Or it can be one of your own custom applications or services. For example, Amazon Aurora generates an event when you create or modify an RDS Proxy. Amazon Aurora delivers events to CloudWatch Events and Amazon EventBridge in near-real time. Following, you can find a list of RDS Proxy events that you can subscribe to and an example of an RDS Proxy event.

For more information about working with events, see the following:

- For instructions on how to view events by using the AWS Management Console, AWS CLI, or RDS API, see [Viewing Amazon RDS events \(p. 569\)](#).
- To learn how to configure Amazon Aurora to send events to EventBridge, see [Creating a rule that triggers on an Amazon Aurora event \(p. 587\)](#).

## RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

Category	RDS event ID	Description
configuration change	RDS-EVENT-0204	RDS modified the DB proxy (RDS Proxy).
configuration change	RDS-EVENT-0207	RDS modified the endpoint of the DB proxy (RDS Proxy).
configuration change	RDS-EVENT-0213	RDS detected the addition of the DB instance and automatically added it to the target group of the DB proxy (RDS Proxy).

Category	RDS event ID	Description
configuration change	RDS-EVENT-0214	RDS detected the deletion of the DB instance and automatically removed it from the target group of the DB proxy (RDS Proxy).
configuration change	RDS-EVENT-0215	RDS detected the deletion of the DB cluster and automatically removed it from the target group of the DB proxy (RDS Proxy).
creation	RDS-EVENT-0203	RDS created the DB proxy (RDS Proxy).
creation	RDS-EVENT-0206	RDS created the endpoint for the DB proxy (RDS Proxy).
deletion	RDS-EVENT-0205	RDS deleted the DB proxy (RDS Proxy).
deletion	RDS-EVENT-0208	RDS deleted the endpoint of DB proxy (RDS Proxy).

The following is an example of an RDS Proxy event in JSON format. The event shows that RDS modified the endpoint named `my-endpoint` of the RDS Proxy named `my-rds-proxy`. The event ID is RDS-EVENT-0207.

```

## RDS Proxy command-line examples

To see how combinations of connection commands and SQL statements interact with RDS Proxy, look at the following examples.

### Examples

- [Preserving Connections to a MySQL Database Across a Failover](#)
- [Adjusting the `max\_connections` Setting for an Aurora DB Cluster](#)

### Example Preserving connections to a MySQL database across a failover

This MySQL example demonstrates how open connections continue working during a failover, for example when you reboot a database or it becomes unavailable due to a problem. This example uses a proxy named `the-proxy` and an Aurora DB cluster with DB instances `instance-8898` and `instance-9814`. When you run the `failover-db-cluster` command from the Linux command line, the writer instance that the proxy is connected to changes to a different DB instance. You can see that the DB instance associated with the proxy changes while the connection remains open.

```
$ mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p
Enter password:
...
mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-9814      |
+-----+
1 row in set (0.01 sec)

mysql>
[1]+  Stopped                  mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -
u admin_user -p
$ # Initially, instance-9814 is the writer.
$ aws rds failover-db-cluster --db-cluster-identifier cluster-56-2019-11-14-1399
JSON output
$ # After a short time, the console shows that the failover operation is complete.
$ # Now instance-8898 is the writer.
$ fg
mysql -h the-proxy.proxy-demo.us.us-east-1.rds.amazonaws.com -u admin_user -p

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-8898      |
+-----+
1 row in set (0.01 sec)

mysql>
[1]+  Stopped                  mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -
u admin_user -p
$ aws rds failover-db-cluster --db-cluster-identifier cluster-56-2019-11-14-1399
JSON output
$ # After a short time, the console shows that the failover operation is complete.
$ # Now instance-9814 is the writer again.
$ fg
mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-9814      |
+-----+
1 row in set (0.01 sec)
+-----+-----+
| Variable_name | Value   |

| hostname     | ip-10-1-3-178 |
+-----+-----+
1 row in set (0.02 sec)
```

### Example Adjusting the max\_connections setting for an Aurora DB cluster

This example demonstrates how you can adjust the `max_connections` setting for an Aurora MySQL DB cluster. To do so, you create your own DB cluster parameter group based on the default parameter settings for clusters that are compatible with MySQL 5.6 or 5.7. You specify a value for the `max_connections` setting, overriding the formula that sets the default value. You associate the DB cluster parameter group with your DB cluster.

```
export REGION=us-east-1
export CLUSTER_PARAM_GROUP=rds-proxy-mysql-56-max-connections-demo
export CLUSTER_NAME=rds-proxy-mysql-56

aws rds create-db-parameter-group --region $REGION \
--db-parameter-group-family aurora5.6 \
--db-parameter-group-name $CLUSTER_PARAM_GROUP \
--description "Aurora MySQL 5.6 cluster parameter group for RDS Proxy demo."

aws rds modify-db-cluster --region $REGION \
--db-cluster-identifier $CLUSTER_NAME \
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP

echo "New cluster param group is assigned to cluster:"
aws rds describe-db-clusters --region $REGION \
--db-cluster-identifier $CLUSTER_NAME \
--query '*[*].{DBClusterParameterGroup:DBClusterParameterGroup}'

echo "Current value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
--query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
--output text | grep "max_connections"

echo -n "Enter number for max_connections setting: "
read answer

aws rds modify-db-cluster-parameter-group --region $REGION --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
--parameters "ParameterName=max_connections,ParameterValue=$answer,ApplyMethod=immediate"

echo "Updated value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
--query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
--output text | grep "max_connections"
```

## Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for read/write requests using the default endpoint of a proxy. For more information about proxy endpoints, see [Working with Amazon RDS Proxy endpoints \(p. 1458\)](#).

### Topics

- [Verifying connectivity for a proxy \(p. 1476\)](#)
- [Common issues and solutions \(p. 1477\)](#)

## Verifying connectivity for a proxy

You can use the following commands to verify that all components of the connection mechanism can communicate with the other components.

Examine the proxy itself using the [describe-db-proxies](#) command. Also examine the associated target group using the [describe-db-proxy-target-groups](#). Check that the details of the targets match the RDS DB instance or Aurora DB cluster that you intend to associate with the proxy. Use commands such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the [describe-db-proxy-targets](#) command. Use a command such as the following.

```
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME
```

The output of the [describe-db-proxy-targets](#) command includes a `TargetHealth` field. You can examine the fields `State`, `Reason`, and `Description` inside `TargetHealth` to check if the proxy can communicate with the underlying DB instance.

- A `State` value of `AVAILABLE` indicates that the proxy can connect to the DB instance.
- A `State` value of `UNAVAILABLE` indicates a temporary or permanent connection problem. In this case, examine the `Reason` and `Description` fields. For example, if `Reason` has a value of `PENDING_PROXY_CAPACITY`, try connecting again after the proxy finishes its scaling operation. If `Reason` has a value of `UNREACHABLE`, `CONNECTION_FAILED`, or `AUTH_FAILURE`, use the explanation from the `Description` field to help you diagnose the issue.
- The `State` field might have a value of `REGISTERING` for a brief time before changing to `AVAILABLE` or `UNAVAILABLE`.

If the following Netcat command (`nc`) is successful, you can access the proxy endpoint from the EC2 instance or other system where you're logged in. This command reports failure if you're not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can't log into the proxy unless you're in the same VPC.

```
nc -zx MySQL_proxy_endpoint 3306
nc -zx PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the RDS DB instance or Aurora DB cluster that the proxy connects to.

```
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.

```
aws secretsmanager list-secrets
aws secretsmanager get-secret-value --secret-id your_secret_id
```

Make sure that the `SecretString` field displayed by `get-secret-value` is encoded as a JSON string that includes `username` and `password` fields. The following example shows the format of the `SecretString` field.

```
{
    "ARN": "some_arn",
    "Name": "some_name",
    "VersionId": "some_version_id",
    "SecretString": '{"username":"some_username","password":"some_password"}',
    "VersionStages": [ "some_stage" ],
    "CreatedDate": some_timestamp
}
```

## Common issues and solutions

For possible causes and solutions to some common problems that you might encounter using RDS Proxy, see the following.

You might encounter the following issues while creating a new proxy or connecting to a proxy.

Error	Causes or workarounds
403: The security token included in the request is invalid	Select an existing IAM role instead of choosing to create a new one.

You might encounter the following issues while connecting to a MySQL proxy.

Error	Causes or workarounds
ERROR 1040 (HY000): Connections rate limit exceeded ( <i>limit_value</i> )	The rate of connection requests from the client to the proxy has exceeded the limit.
ERROR 1040 (HY000): IAM authentication rate limit exceeded	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.
ERROR 1040 (HY000): Number simultaneous connections exceeded ( <i>limit_value</i> )	The number of simultaneous connection requests from the client to the proxy exceeded the limit.
ERROR 1045 (28000): Access denied for user ' <i>DB_USER</i> '@'%' (using password: YES)	Some possible reasons include the following: <ul style="list-style-type: none"> <li>• The Secrets Manager secret used by the proxy doesn't match the user name and password of an existing database user. Either update the credentials in the Secrets Manager secret, or make sure the database user exists and has the same password as in the secret.</li> </ul>
ERROR 1105 (HY000): Unknown error	An unknown error occurred.

Error	Causes or workarounds
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of <code>value</code>	The value set for the <code>character_set_client</code> parameter is not valid. For example, the value <code>ucs2</code> is not valid because it can crash the MySQL server.
ERROR 3159 (HY000): This RDS Proxy requires TLS connections.	You enabled the setting <b>Require Transport Layer Security</b> in the proxy but your connection included the parameter <code>ssl-mode=DISABLED</code> in the MySQL client. Do either of the following: <ul style="list-style-type: none"> <li>Disable the setting <b>Require Transport Layer Security</b> for the proxy.</li> <li>Connect to the database using the minimum setting of <code>ssl-mode=REQUIRED</code> in the MySQL client.</li> </ul>
ERROR 2026 (HY000): SSL connection error: Internal Server Error	The TLS handshake to the proxy failed. Some possible reasons include the following: <ul style="list-style-type: none"> <li>SSL is required but the server doesn't support it.</li> <li>An internal server error occurred.</li> <li>A bad handshake occurred.</li> </ul>
ERROR 9501 (HY000): Timed-out waiting to acquire database connection	The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following: <ul style="list-style-type: none"> <li>The proxy is unable to establish a database connection because the maximum connections have been reached</li> <li>The proxy is unable to establish a database connection because the database is unavailable.</li> </ul>

You might encounter the following issues while connecting to a PostgreSQL proxy.

Error	Cause	Solution
IAM authentication is allowed only with SSL connections.	The user tried to connect to the database using IAM authentication with the setting <code>sslmode=disable</code> in the PostgreSQL client.	The user needs to connect to the database using the minimum setting of <code>sslmode=require</code> in the PostgreSQL client. For more information, see the <a href="#">PostgreSQL SSL support</a> documentation.
This RDS Proxy requires TLS connections.	The user enabled the option <b>Require Transport Layer Security</b> but tried to connect with <code>sslmode=disable</code> in the PostgreSQL client.	To fix this error, do one of the following: <ul style="list-style-type: none"> <li>Disable the proxy's <b>Require Transport Layer Security</b> option.</li> <li>Connect to the database using the minimum setting of <code>sslmode=allow</code> in the PostgreSQL client.</li> </ul>
IAM authentication failed for user <code>user_name</code> . Check the IAM	This error might be due to the following reasons:	To fix this error, do the following:

Error	Cause	Solution
token for this user and try again.	<ul style="list-style-type: none"> <li>The client supplied the incorrect IAM user name.</li> <li>The client supplied an incorrect IAM authorization token for the user.</li> <li>The client is using an IAM policy that does not have the necessary permissions.</li> <li>The client supplied an expired IAM authorization token for the user.</li> </ul>	<ol style="list-style-type: none"> <li>Confirm that the provided IAM user exists.</li> <li>Confirm that the IAM authorization token belongs to the provided IAM user.</li> <li>Confirm that the IAM policy has adequate permissions for RDS.</li> <li>Check the validity of the IAM authorization token used.</li> </ol>
This RDS proxy has no credentials for the role <b>role_name</b> . Check the credentials for this role and try again.	There is no Secrets Manager secret for this role.	Add a Secrets Manager secret for this role.
RDS supports only IAM or MD5 authentication.	The database client being used to connect to the proxy is using an authentication mechanism not currently supported by the proxy, such as SCRAM-SHA-256.	If you're not using IAM authentication, use the MD5 password authentication only.
A user name is missing from the connection startup packet. Provide a user name for this connection.	The database client being used to connect to the proxy isn't sending a user name when trying to establish a connection.	Make sure to define a user name when setting up a connection to the proxy using the PostgreSQL client of your choice.
Feature not supported: RDS Proxy supports only version 3.0 of the PostgreSQL messaging protocol.	The PostgreSQL client used to connect to the proxy uses a protocol older than 3.0.	Use a newer PostgreSQL client that supports the 3.0 messaging protocol. If you're using the PostgreSQL psql CLI, use a version greater than or equal to 7.4.
Feature not supported: RDS Proxy currently doesn't support streaming replication mode.	The PostgreSQL client used to connect to the proxy is trying to use the streaming replication mode, which isn't currently supported by RDS Proxy.	Turn off the streaming replication mode in the PostgreSQL client being used to connect.
Feature not supported: RDS Proxy currently doesn't support the option <b>option_name</b> .	Through the startup message, the PostgreSQL client used to connect to the proxy is requesting an option that isn't currently supported by RDS Proxy.	Turn off the option being shown as not supported from the message above in the PostgreSQL client being used to connect.
The IAM authentication failed because of too many competing requests.	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.	Reduce the rate in which connections using IAM authentication from a PostgreSQL client are established.

Error	Cause	Solution
The maximum number of client connections to the proxy exceeded <i>number_value</i> .	The number of simultaneous connection requests from the client to the proxy exceeded the limit.	Reduce the number of active connections from PostgreSQL clients to this RDS proxy.
Rate of connection to proxy exceeded <i>number_value</i> .	The rate of connection requests from the client to the proxy has exceeded the limit.	Reduce the rate in which connections from a PostgreSQL client are established.
The password that was provided for the role <i>role_name</i> is wrong.	The password for this role doesn't match the Secrets Manager secret.	Check the secret for this role in Secrets Manager to see if the password is the same as what's being used in your PostgreSQL client.
The IAM authentication failed for the role <i>role_name</i> . Check the IAM token for this role and try again.	There is a problem with the IAM token used for IAM authentication.	Generate a new authentication token and use it in a new connection.
IAM is allowed only with SSL connections.	A client tried to connect using IAM authentication, but SSL wasn't enabled.	Enable SSL in the PostgreSQL client.
Unknown error.	An unknown error occurred.	Reach out to AWS Support to investigate the issue.
Timed-out waiting to acquire database connection.	<p>The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following:</p> <ul style="list-style-type: none"> <li>The proxy can't establish a database connection because the maximum connections have been reached.</li> <li>The proxy can't establish a database connection because the database is unavailable.</li> </ul>	<p>Possible solutions are the following:</p> <ul style="list-style-type: none"> <li>Check the target of the RDS DB instance or Aurora DB cluster status to see if it's unavailable.</li> <li>Check if there are long-running transactions and/or queries being executed. They can use database connections from the connection pool for a long time.</li> </ul>
Request returned an error: <i>database_error</i> .	The database connection established from the proxy returned an error.	The solution depends on the specific database error. One example is: Request returned an error: database "your-database-name" does not exist. This means the specified database name, or the user name used as a database name (in case a database name hasn't been specified), doesn't exist in the database server.

# Using RDS Proxy with AWS CloudFormation

You can use RDS Proxy with AWS CloudFormation. Doing so helps you to create groups of related resources, including a proxy that can connect to a newly created Amazon RDS DB instance or Aurora DB cluster. RDS Proxy support in AWS CloudFormation involves two new registry types: `DBProxy` and `DBProxyTargetGroup`.

The following listing shows a sample AWS CloudFormation template for RDS Proxy.

```
Resources:
  DBProxy:
    Type: AWS::RDS::DBProxy
    Properties:
      DBProxyName: CanaryProxy
      EngineFamily: MYSQL
      RoleArn:
        Fn::ImportValue: SecretReaderRoleArn
      Auth:
        - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
      VpcSubnetIds:
        Fn::Split: [",", "Fn::ImportValue": SubnetIds]

  ProxyTargetGroup:
    Type: AWS::RDS::DBProxyTargetGroup
    Properties:
      DBProxyName: CanaryProxy
      TargetGroupName: default
      DBInstanceIdentifiers:
        - Fn::ImportValue: DBInstanceName
    DependsOn: DBProxy
```

For more information about the Amazon RDS and Aurora resources that you can create using AWS CloudFormation, see [RDS resource type reference](#).

# Using Aurora Serverless v2

Aurora Serverless v2 is an on-demand, autoscaling configuration for Amazon Aurora. Aurora Serverless v2 helps to automate the processes of monitoring the workload and adjusting the capacity for your databases. Capacity is adjusted automatically based on application demand. You're charged only for the resources that your DB clusters consume. Thus, Aurora Serverless v2 can help you to stay within budget and avoid paying for computer resources that you don't use.

This type of automation is especially valuable for multitenant databases, distributed databases, development and test systems, and other environments with highly variable and unpredictable workloads.

## Topics

- [Aurora Serverless v2 use cases \(p. 1482\)](#)
- [Advantages of Aurora Serverless v2 \(p. 1483\)](#)
- [How Aurora Serverless v2 works \(p. 1484\)](#)
- [Requirements for Aurora Serverless v2 \(p. 1490\)](#)

- [Managing Aurora Serverless v2 \(p. 1509\)](#)
- [Performance and scaling for Aurora Serverless v2 \(p. 1526\)](#)

## Aurora Serverless v2 use cases

Many kinds of workloads can benefit from Aurora Serverless v2. Aurora Serverless v2 is especially useful for the following use cases:

- **Variable workloads** – You're running workloads that have sudden and unpredictable increases in activity. An example is a traffic site that sees a surge of activity when it starts raining. Another is an e-commerce site with increased traffic when you offer sales or special promotions. With Aurora Serverless v2, your database automatically scales capacity to meet the needs of the application's peak load and scales back down when the surge of activity is over. With Aurora Serverless v2, you no longer need to provision for peak or average capacity. You can specify an upper capacity limit to handle the worst-case situation, and that capacity isn't used unless it's needed.

The granularity of scaling in Aurora Serverless v2 helps you to match capacity closely to your database's needs. For a provisioned cluster, scaling up requires adding a whole new DB instance. For an Aurora Serverless v1 cluster, scaling up requires doubling the number of Aurora capacity units (ACUs) for the cluster, such as from 16 to 32 or 32 to 64. In contrast, Aurora Serverless v2 can add half an ACU when only a little more capacity is needed. It can add 0.5, 1, 1.5, 2, or additional half-ACUs based on the additional capacity needed to handle an increase in workload. And it can remove 0.5, 1, 1.5, 2, or additional half-ACUs when the workload decreases and that capacity is no longer needed.

- **Multi-tenant applications** – With Aurora Serverless v2, you don't have to individually manage database capacity for each application in your fleet. Aurora Serverless v2 manages individual database capacity for you.

You can create a cluster for each tenant. That way, you can use features such as cloning, snapshot restore, and Aurora global databases to enhance high availability and disaster recovery as appropriate for each tenant.

Each tenant might have specific busy and idle periods depending on the time of day, time of year, promotional events, and so on. Each cluster can have a wide capacity range. That way, clusters with

low activity incur minimal DB instance charges. Any cluster can quickly scale up to handle periods of high activity.

- **New applications** – You're deploying a new application and you're unsure about the DB instance size you need. By using Aurora Serverless v2, you can set up a cluster with one or many DB instances and have the database autoscale to the capacity requirements of your application.
- **Development and testing** – With Aurora Serverless v2, you can create Aurora Serverless v2 DB instances with a low minimum capacity instead of using T DB instance classes. You can set the maximum capacity high enough that those DB instances can still run substantial workloads without running low on memory. When the database isn't in use, all the DB instances scale down to avoid unnecessary charges.

**Tip**

To make it convenient to use Aurora Serverless v2 in development and test environments, the AWS Management Console provides the **Easy create** shortcut when you create a new cluster. If you choose the **Dev/Test** option, Aurora creates a cluster with an Aurora Serverless v2 DB instance and a capacity range that's typical for a development and test system.

- **Mixed-use applications** – Suppose that you have an online transaction processing (OLTP) application, but you periodically experience spikes in query traffic. By specifying promotion tiers for the Aurora Serverless v2 DB instances in a cluster, you can configure your cluster so that the reader DB instances can scale independently of the writer DB instance to handle the additional load. When the usage spike subsides, the reader DB instances scale back down to match the capacity of the writer DB instance.
- **Capacity planning** – Suppose that you usually adjust your database capacity, or verify the optimal database capacity for your workload, by modifying the DB instance classes of all the DB instances in a cluster. With Aurora Serverless v2, you can avoid this administrative overhead. You can determine the appropriate minimum and maximum capacity by running the workload and checking how much the DB instances actually scale.

You can modify existing DB instances from provisioned to Aurora Serverless v2 or from Aurora Serverless v2 to provisioned. You don't need to create a new cluster or a new DB instance in such cases.

With an Aurora global database, you might not need as much capacity for the secondary clusters as in the primary cluster. You can use Aurora Serverless v2 DB instances in the secondary clusters. That way, the cluster capacity can scale up if a secondary region is promoted and takes over your application's workload.

## Starting to use Aurora Serverless v2 for existing provisioned workloads

Suppose that you already have an Aurora application running on a provisioned cluster. You can check how the application would work with Aurora Serverless v2 by adding one or more Aurora Serverless v2 DB instances to the existing cluster as reader DB instances. You can check how often the reader DB instances scale up and down. You can use the Aurora failover mechanism to promote an Aurora Serverless v2 DB instance to be the writer and check how it handles the read/write workload. That way, you can switch over with minimal downtime and without changing the endpoint that your client applications use. For details on the procedure to convert existing clusters to Aurora Serverless v2, see [Getting started with Aurora Serverless v2 \(p. 1492\)](#).

## Advantages of Aurora Serverless v2

Aurora Serverless v2 is intended for variable or "spiky" workloads. With such unpredictable workloads, you might have difficulty planning when to change your database capacity. You might also have trouble making capacity changes quickly enough using the familiar mechanisms such as adding DB instances or

changing DB instance classes. Aurora Serverless v2 provides the following advantages to help with such use cases:

- **Simpler capacity management than provisioned** – Aurora Serverless v2 reduces the effort for planning DB instance sizes and resizing DB instances as the workload changes. It also reduces the effort for maintaining consistent capacity for all the DB instances in a cluster.
- **Faster and easier scaling during periods of high activity** – Aurora Serverless v2 scales compute and memory capacity as needed, with no disruption to client transactions or your overall workload. The ability to use reader DB instances with Aurora Serverless v2 helps you to take advantage of horizontal scaling in addition to vertical scaling. The ability to use Aurora global databases means that you can spread your Aurora Serverless v2 read workload across multiple AWS Regions. This capability is more convenient than the scaling mechanisms for provisioned clusters. It's also faster and more granular than the scaling capabilities in Aurora Serverless v1.
- **Cost-effective during periods of low activity** – Aurora Serverless v2 helps you to avoid overprovisioning your DB instances. Aurora Serverless v2 adds resources in granular increments when DB instances scale up. You pay only for the database resources that you consume. Aurora Serverless v2 resource usage is measured on a per-second basis. That way, when a DB instance scales down, the reduced resource usage is registered right away.
- **Greater feature parity with provisioned** – You can use many Aurora features with Aurora Serverless v2 that aren't available for Aurora Serverless v1. For example, with Aurora Serverless v2 you can use reader DB instances, global databases, AWS Identity and Access Management (IAM) database authentication, and Performance Insights. You can also use many more configuration parameters than with Aurora Serverless v1.

In particular, with Aurora Serverless v2 you can take advantage of the following features from provisioned clusters:

- **Reader DB instances** – Aurora Serverless v2 can take advantage of reader DB instances to scale horizontally. When a cluster contains one or more reader DB instances, the cluster can fail over immediately in case of problems with the writer DB instance. This is a capability that isn't available with Aurora Serverless v1.
- **Multi-AZ clusters** – You can distribute the Aurora Serverless v2 DB instances of a cluster across multiple Availability Zones (AZs). Setting up a Multi-AZ cluster helps to ensure business continuity even in the rare case of issues that affect an entire AZ. This is a capability that isn't available with Aurora Serverless v1.
- **Global databases** – You can use Aurora Serverless v2 in combination with Aurora global databases to create additional read-only copies of your cluster in other AWS Regions for disaster recovery purposes.
- **RDS Proxy** – You can use Amazon RDS Proxy to allow your applications to pool and share database connections to improve their ability to scale.
- **Faster, more granular, less disruptive scaling than Aurora Serverless v1** – Aurora Serverless v2 can scale up and down faster. Scaling can change capacity by as little as 0.5 ACUs, instead of doubling or halving the number of ACUs. Scaling typically happens with no pause in processing at all. Scaling doesn't involve an event that you have to be aware of, as with Aurora Serverless v1. Scaling can happen while SQL statements are running and transactions are open, without the need to wait for a quiet point.

## How Aurora Serverless v2 works

Following, you can find an overview that describes how Aurora Serverless v2 works.

### Topics

- [Aurora Serverless v2 overview \(p. 1485\)](#)
- [Configurations for Aurora clusters \(p. 1486\)](#)

- [Aurora Serverless v2 capacity \(p. 1486\)](#)
- [Aurora Serverless v2 scaling \(p. 1487\)](#)
- [Aurora Serverless v2 and high availability \(p. 1488\)](#)
- [Aurora Serverless v2 and storage \(p. 1489\)](#)
- [Configuration parameters for Aurora clusters \(p. 1489\)](#)

## Aurora Serverless v2 overview

*Amazon Aurora Serverless v2* is suitable for the most demanding, highly variable workloads. For example, your database usage might be heavy for a short period of time, followed by long periods of light activity or no activity at all. Some examples are retail, gaming, or sports websites with periodic promotional events, and databases that produce reports when needed. Others are development and testing environments, and new applications where usage might ramp up quickly. For cases such as these and many others, configuring capacity correctly in advance isn't always possible with the provisioned model. It can also result in higher costs if you overprovision and have capacity that you don't use.

In contrast, *Aurora provisioned clusters* are suitable for steady workloads. With provisioned clusters, you choose a DB instance class that has a predefined amount of memory, CPU power, I/O bandwidth, and so on. If your workload changes, you manually modify the instance class of your writer and readers. The provisioned model works well when you can adjust capacity in advance of expected consumption patterns and it's acceptable to have brief outages while you change the instance class of the writer and readers in your cluster.

Aurora Serverless v2 is architected from the ground up to support serverless DB clusters that are instantly scalable. Aurora Serverless v2 is engineered to provide the same degree of security and isolation as with provisioned writers and readers. These aspects are crucial in multitenant serverless cloud environments. The dynamic scaling mechanism has very little overhead so that it can respond quickly to changes in the database workload. It's also powerful enough to meet dramatic increases in processing demand.

By using Aurora Serverless v2, you can create an Aurora DB cluster without being locked into a specific database capacity for each writer and reader. You specify the minimum and maximum capacity range. Aurora scales each Aurora Serverless v2 writer or reader in the cluster within that capacity range. By using a Multi-AZ cluster where each writer or reader can scale dynamically, you can take advantage of dynamic scaling and high availability.

Aurora Serverless v2 scales the database resources automatically based on your minimum and maximum capacity specifications. Scaling is fast because most scaling events operations keep the writer or reader on the same host. In the rare cases that an Aurora Serverless v2 writer or reader is moved from one host to another, Aurora Serverless v2 manages the connections automatically. You don't need to change your database client application code or your database connection strings.

With Aurora Serverless v2, as with provisioned clusters, storage capacity and compute capacity are separate. When we refer to Aurora Serverless v2 capacity and scaling, it's always compute capacity that's increasing or decreasing. Thus, your cluster can contain many terabytes of data even when the CPU and memory capacity scale down to low levels.

Instead of provisioning and managing database servers, you specify database capacity. For details about Aurora Serverless v2 capacity, see [Aurora Serverless v2 capacity \(p. 1486\)](#). The actual capacity of each Aurora Serverless v2 writer or reader varies over time, depending on your workload. For details about that mechanism, see [Aurora Serverless v2 scaling \(p. 1487\)](#).

### Important

With Aurora Serverless v1, your cluster has a single measure of compute capacity that can scale between the minimum and maximum capacity values. With Aurora Serverless v2, your cluster can contain readers in addition to the writer. Each Aurora Serverless v2 writer and reader can

scale between the minimum and maximum capacity values. Thus, the total capacity of your Aurora Serverless v2 cluster depends on both the capacity range that you define for your DB cluster and the number of writers and readers in the cluster. At any specific time, you are only charged for the Aurora Serverless v2 capacity that is being actively used in your Aurora DB cluster.

## Configurations for Aurora clusters

For each of your Aurora DB clusters, you can choose any combination of Aurora Serverless v2 capacity, provisioned capacity, or both.

You can set up a cluster that contains both Aurora Serverless v2 and provisioned capacity, called a *mixed-configuration cluster*. For example, suppose that you need more read/write capacity than is available for an Aurora Serverless v2 writer. In this case, you can set up the cluster with a very large provisioned writer. In that case, you can still use Aurora Serverless v2 for the readers. Or suppose that the write workload for your cluster varies but the read workload is steady. In this case, you can set up your cluster with an Aurora Serverless v2 writer and one or more provisioned readers.

You can also set up a DB cluster where all the capacity is managed by Aurora Serverless v2. To do this, you can create a new cluster and use Aurora Serverless v2 from the start. Or you can replace all the provisioned capacity in an existing cluster with Aurora Serverless v2. For example, some of the upgrade paths from older engine versions require starting with a provisioned writer and replacing it with an Aurora Serverless v2 writer. For the procedures to create a new DB cluster with Aurora Serverless v2 or to switch an existing DB cluster to Aurora Serverless v2, see [Creating a cluster that uses Aurora Serverless v2 \(p. 1506\)](#) and [Switching from a provisioned cluster to Aurora Serverless v2 \(p. 1495\)](#).

If you don't use Aurora Serverless v2 at all in a DB cluster, all the writers and readers in the DB cluster are *provisioned*. This is the oldest and most common kind of DB cluster that most users are familiar with. In fact, before Aurora Serverless, there wasn't a special name for this kind of Aurora DB cluster. Provisioned capacity is constant. The charges are relatively easy to forecast. However, you have to predict in advance how much capacity you need. In some cases, your predictions might be inaccurate or your capacity needs might change. In these cases, your DB cluster can become underprovisioned (slower than you want) or overprovisioned (more expensive than you want).

## Aurora Serverless v2 capacity

The unit of measure for Aurora Serverless v2 is the *Aurora capacity unit (ACU)*. Aurora Serverless v2 capacity isn't tied to the DB instance classes that you use for provisioned clusters.

Each ACU is a combination of approximately 2 gibibytes (GiB) of memory, corresponding CPU, and networking. You specify the database capacity range using this unit of measure. The `ServerlessDatabaseCapacity` and `ACUUtilization` metrics help you to determine how much capacity your database is actually using and where that capacity falls within the specified range.

At any moment in time, each Aurora Serverless v2 DB writer or reader has a *capacity*. The capacity is represented as a floating-point number representing ACUs. The capacity increases or decreases whenever the writer or reader scales. This value is measured every second. For each DB cluster where you intend to use Aurora Serverless v2, you define a *capacity range*: the minimum and maximum capacity values that each Aurora Serverless v2 writer or reader can scale between. The capacity range is the same for each Aurora Serverless v2 writer or reader in a DB cluster. Each Aurora Serverless v2 writer or reader has its own capacity, falling somewhere in that range.

The largest Aurora Serverless v2 capacity that you can define is 128 ACUs. For all the considerations when choosing the maximum capacity value, see [Choosing the maximum Aurora Serverless v2 capacity setting for a cluster \(p. 1528\)](#).

The smallest Aurora Serverless v2 capacity that you can define is 0.5 ACUs. You can specify a higher number if it's less than or equal to the maximum capacity value. Setting the minimum capacity to a small

number lets lightly loaded DB clusters consume minimal compute resources. At the same time, they stay ready to accept connections immediately and scale up when they become busy.

We recommend setting the minimum to a value that allows each DB writer or reader to hold the working set of the application in the buffer pool. That way, the contents of the buffer pool aren't discarded during idle periods. For all the considerations when choosing the minimum capacity value, see [Choosing the minimum Aurora Serverless v2 capacity setting for a cluster \(p. 1527\)](#).

Depending on how you configure the readers in a Multi-AZ DB cluster, their capacities can be tied to the capacity of the writer or independently. For details about how to do that, see [Aurora Serverless v2 scaling \(p. 1487\)](#).

Monitoring Aurora Serverless v2 involves measuring the capacity values for the writer and readers in your DB cluster over time. If your database doesn't scale down to the minimum capacity, you can take actions such as adjusting the minimum and optimizing your database application. If your database consistently reaches its maximum capacity, you can take actions such as increasing the maximum. You can also optimize your database application and spread the query load across more readers.

The charges for Aurora Serverless v2 capacity are measured in terms of ACU-hours. For information about how Aurora Serverless v2 charges are calculated, see the [Aurora pricing page](#).

Suppose that the total number of writers and readers in your cluster is  $N$ . In that case, the cluster consumes approximately  $n \times \text{minimum ACUs}$  when you aren't running any database operations. Aurora itself might run monitoring or maintenance operations that cause some small amount of load. That cluster consumes no more than  $n \times \text{maximum ACUs}$  when the database is running at full capacity.

For more details about choosing appropriate minimum and maximum ACU values, see [Choosing the Aurora Serverless v2 capacity range for an Aurora cluster \(p. 1527\)](#). The minimum and maximum ACU values that you specify also affect the way some of the Aurora configuration parameters work for Aurora Serverless v2. For details about the interaction between the capacity range and configuration parameters, see [Working with parameter groups for Aurora Serverless v2 \(p. 1535\)](#).

## Aurora Serverless v2 scaling

For each Aurora Serverless v2 writer or reader, Aurora continuously tracks utilization of resources such as CPU, memory, and network. These measurements collectively are called the *load*. The load includes the database operations performed by your application. It also includes background processing for the database server and Aurora administrative tasks. When capacity is constrained by any of these, Aurora Serverless v2 scales up. Aurora Serverless v2 also scales up when it detects performance issues that it can resolve by doing so. You can monitor resource utilization and how it affects Aurora Serverless v2 scaling by using the procedures in [Important Amazon CloudWatch metrics for Aurora Serverless v2 \(p. 1539\)](#) and [Monitoring Aurora Serverless v2 performance with Performance Insights \(p. 1542\)](#).

The load can vary across the writer and readers in your DB cluster. The writer handles all data definition language (DDL) statements, such as `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE`. The writer also handles all data manipulation language (DML) statements, such as `INSERT` and `UPDATE`. Readers can process read-only statements, such as `SELECT` queries.

*Scaling* is the operation that increases or decreases Aurora Serverless v2 capacity for your database. With Aurora Serverless v2, each writer and reader has its own current capacity value, measured in ACUs. Aurora Serverless v2 scales a writer or reader up to a higher capacity when its current capacity is too low to handle the load. It scales the writer or reader down to a lower capacity when its current capacity is higher than needed.

Unlike Aurora Serverless v1, which scales by doubling the capacity each time the DB cluster reaches a threshold, Aurora Serverless v2 can increase capacity incrementally. When your workload demand begins to reach the current database capacity of a writer or reader, Aurora Serverless v2 increases the number of ACUs for that writer or reader. Aurora Serverless v2 scales capacity in the increments required to provide

the best performance for the resources consumed. Scaling happens in increments as small as 0.5 ACUs. The larger the current capacity, the larger the scaling increment and thus the faster scaling can happen.

Because Aurora Serverless v2 scaling is so frequent, granular, and nondisruptive, it doesn't cause discrete events in the AWS Management Console the way that Aurora Serverless v1 does. Instead, you can measure the Amazon CloudWatch metrics such as `ServerlessDatabaseCapacity` and `ACUUtilization` and track their minimum, maximum, and average values over time. To learn more about Aurora metrics, see [Monitoring metrics in an Amazon Aurora cluster \(p. 427\)](#). For tips about monitoring Aurora Serverless v2, see [Important Amazon CloudWatch metrics for Aurora Serverless v2 \(p. 1539\)](#).

You can choose to make a reader scale at the same time as the associated writer, or independently from the writer. You do so by specifying the promotion tier for that reader.

- Readers in promotion tiers 0 and 1 scale at the same time as the writer. That scaling behavior makes readers in priority tiers 0 and 1 ideal for availability. That's because they are always sized to the right capacity to take over the workload from the writer in case of failover.
- Readers in promotion tiers 2–15 scale independently from the writer. Each reader remains within the minimum and maximum ACU values that you specified for your cluster. When a reader scales independently of the associated writer DB, it can become idle and scale down while the writer continues to process a high volume of transactions. It's still available as a failover target, if no other readers are available in lower promotion tiers. However, if it's promoted to be the writer, it might need to scale up to handle the full workload of the writer.

For details about promotion tiers, see [Choosing the promotion tier for an Aurora Serverless v2 reader \(p. 1521\)](#).

The notions of scaling points and associated timeout periods from Aurora Serverless v1 don't apply in Aurora Serverless v2. Aurora Serverless v2 scaling can happen while database connections are open, while SQL transactions are in process, while tables are locked, and while temporary tables are in use. Aurora Serverless v2 doesn't wait for a quiet point to begin scaling. Scaling doesn't disrupt any database operations that are underway.

If your workload requires more read capacity than is available with a single writer and a single reader, you can add multiple Aurora Serverless v2 readers to the cluster. Each Aurora Serverless v2 reader can scale within the range of minimum and maximum capacity values that you specified for your DB cluster. You can use the cluster's reader endpoint to direct read-only sessions to the readers and reduce the load on the writer.

Whether Aurora Serverless v2 performs scaling, and how fast scaling occurs once it starts, also depends on the minimum and maximum ACU settings for the cluster. In addition, it depends on whether a reader is configured to scale along with the writer or independently from it. For details about the factors that affect Aurora Serverless v2 scaling, see [Performance and scaling for Aurora Serverless v2 \(p. 1526\)](#).

**Note**

Currently, Aurora Serverless v2 writers and readers don't scale all the way down to zero ACUs. Idle Aurora Serverless v2 writers and readers can scale down to the minimum ACU value that you specified for the cluster.

That behavior is different than Aurora Serverless v1, which can pause after a period of idleness, but then takes some time to resume when you open a new connection. When your DB cluster with Aurora Serverless v2 capacity isn't needed for some time, you can stop and start clusters as with provisioned DB clusters. For details about stopping and starting clusters, see [Stopping and starting an Amazon Aurora DB cluster \(p. 244\)](#).

## Aurora Serverless v2 and high availability

The way to establish high availability for an Aurora DB cluster is to make it a Multi-AZ DB cluster. A *Multi-AZ Aurora DB cluster* has compute capacity available at all times in more than one Availability Zone (AZ).

That configuration keeps your database up and running even in case of a significant outage. Aurora performs an automatic failover in case of an issue that affects the writer or even the entire AZ. With Aurora Serverless v2, you can choose for the standby compute capacity to scale up and down along with the capacity of the writer. That way, the compute capacity in the second AZ is ready to take over the current workload at any time. At the same time, the compute capacity in all AZs can scale down when the database is idle. For details about how Aurora works with AWS Regions and Availability Zones, see [High availability for Aurora DB instances \(p. 71\)](#).

The Aurora Serverless v2 Multi-AZ capability uses *readers* in addition to the writer. Support for readers is new for Aurora Serverless v2 compared to Aurora Serverless v1. You can add up to 15 Aurora Serverless v2 readers spread across 3 AZs to an Aurora DB cluster.

For business-critical applications that must remain available even in case of an issue that affects your entire cluster or the whole AWS Region, you can set up an Aurora global database. You can use Aurora Serverless v2 capacity in the secondary clusters so they're ready to take over during disaster recovery. They can also scale down when the database isn't busy. For details about Aurora global databases, see [Using Amazon Aurora global databases \(p. 151\)](#).

Aurora Serverless v2 works like provisioned for failover and other high availability features. For more information, see [High availability for Amazon Aurora \(p. 71\)](#).

Suppose that you want to ensure maximum availability for your Aurora Serverless v2 cluster. You can create a reader in addition to the writer. If you assign the reader to promotion tier 0 or 1, whatever scaling happens for the writer also happens for the reader. That way, a reader with identical capacity is always ready to take over for the writer in case of a failover.

Suppose that you want to run quarterly reports for your business at the same time as your cluster continues to process transactions. If you add an Aurora Serverless v2 reader to the cluster and assign it to a promotion tier from 2 through 15, you can connect directly to that reader to run the reports. Depending on how memory-intensive and CPU-intensive the reporting queries are, that reader can scale up to accommodate the workload. It can then scale down again when the reports are finished.

## Aurora Serverless v2 and storage

The storage for each Aurora DB cluster consists of six copies of all your data, spread across three AZs. This built-in data replication applies regardless of whether your DB cluster includes any readers in addition to the writer. That way, your data is safe, even from issues that affect the compute capacity of the cluster.

Aurora Serverless v2 storage has the same reliability and durability characteristics as described in [Amazon Aurora storage and reliability \(p. 67\)](#). That's because the storage for Aurora DB clusters works the same whether the compute capacity uses Aurora Serverless v2 or provisioned.

## Configuration parameters for Aurora clusters

You can adjust all the same cluster and database configuration parameters for clusters with Aurora Serverless v2 capacity as for provisioned DB clusters. However, some capacity-related parameters are handled differently for Aurora Serverless v2. In a mixed-configuration cluster, the parameter values that you specify for those capacity-related parameters still apply to any provisioned writers and readers.

Almost all of the parameters work the same way for Aurora Serverless v2 writers and readers as for provisioned ones. The exceptions are some parameters that Aurora automatically adjusts during scaling, and some parameters that Aurora keeps at fixed values that depend on the maximum capacity setting.

For example, the amount of memory reserved for the buffer cache increases as a writer or reader scales up, and decreases as it scales down. That way, memory can be released when your database isn't busy. Conversely, Aurora automatically sets the maximum number of connections to a value that's appropriate

based on the maximum capacity setting. That way, active connections aren't dropped if the load drops and Aurora Serverless v2 scales down. For information about how Aurora Serverless v2 handles specific parameters, see [Working with parameter groups for Aurora Serverless v2 \(p. 1535\)](#).

## Requirements for Aurora Serverless v2

When you create a cluster where you intend to use Aurora Serverless v2 DB instances, pay attention to the following requirements.

### Topics

- [Aurora Serverless v2 is available in certain AWS Regions \(p. 1490\)](#)
- [Aurora Serverless v2 requires minimum engine versions \(p. 1490\)](#)
- [Clusters that use Aurora Serverless v2 must have a capacity range specified \(p. 1491\)](#)
- [Some provisioned features aren't supported in Aurora Serverless v2 \(p. 1491\)](#)
- [Some Aurora Serverless v2 aspects are different from Aurora Serverless v1 \(p. 1492\)](#)

## Aurora Serverless v2 is available in certain AWS Regions

For the AWS Regions where Aurora Serverless v2 DB instances are currently available, see [Aurora Serverless v2 \(p. 31\)](#).

## Aurora Serverless v2 requires minimum engine versions

Aurora clusters that use Aurora Serverless v2 DB instances must be running one of the following DB engine versions:

- MySQL-compatible DB instances for Aurora Serverless v2 require Aurora MySQL 3.02.0 or higher. This Aurora MySQL version is compatible with MySQL 8.0.
- PostgreSQL-compatible DB instances for Aurora Serverless v2 require Aurora PostgreSQL 13.6 or higher.

For the complete list of supported versions and AWS Regions, see [Aurora Serverless v2 \(p. 31\)](#).

The following example shows the AWS CLI commands to confirm the exact DB engine values you can use with Aurora Serverless v2 for a specific AWS Region. The `--db-instance-class` parameter for Aurora Serverless v2 is always `db.serverless`. The `--engine` parameter can be `aurora-mysql` or `aurora-postgresql`. Substitute the appropriate `--region` and `--engine` values to confirm the `--engine-version` values that you can use. If the command doesn't produce any output, Aurora Serverless v2 isn't available for that combination of AWS Region and DB engine.

```
aws rds describe-orderable-db-instance-options --engine aurora-mysql --db-instance-class db.serverless \
--region my_region --query 'OrderableDBInstanceOptions[].[EngineVersion]' --output text

aws rds describe-orderable-db-instance-options --engine aurora-postgresql --db-instance-class db.serverless \
--region my_region --query 'OrderableDBInstanceOptions[].[EngineVersion]' --output text
```

## Clusters that use Aurora Serverless v2 must have a capacity range specified

An Aurora cluster must have a `ScalingConfigurationInfo` attribute before you can add any DB instances that use the `db.serverless` DB instance class. This attribute specifies the capacity range. Aurora Serverless v2 capacity ranges from a minimum of 0.5 Aurora capacity units (ACU) through 128 ACUs, in increments of 0.5 ACU. Each ACU provides the equivalent of approximately 2 gibibytes (GiB) of RAM and associated CPU and networking. For details about how Aurora Serverless v2 uses the capacity range settings, see [How Aurora Serverless v2 works \(p. 1484\)](#).

You can specify the minimum and maximum ACU values in the AWS Management Console when you create a cluster and associated Aurora Serverless v2 DB instance. You can also specify the `--serverless-v2-scaling-configuration` option in the AWS CLI. Or you can specify the `ServerlessV2ScalingConfiguration` parameter with the Amazon RDS API. You can specify this attribute when you create a cluster or modify an existing cluster. For the procedures to set the capacity range, see [Setting the Aurora Serverless v2 capacity range for a cluster \(p. 1510\)](#). For a detailed discussion of how to pick minimum and maximum capacity values and how those settings affect some database parameters, see [Choosing the Aurora Serverless v2 capacity range for an Aurora cluster \(p. 1527\)](#).

## Some provisioned features aren't supported in Aurora Serverless v2

The following features from Aurora provisioned DB instances currently aren't available for Amazon Aurora Serverless v2:

- Database activity streams (DAS).
- Backtracking for Aurora MySQL. This feature currently isn't available for Aurora MySQL version 3. For details of Aurora MySQL version 3 feature support, see [Aurora MySQL version 3 compatible with MySQL 8.0 \(p. 653\)](#).
- Cluster cache management for Aurora PostgreSQL. The `apg_ccm_enabled` configuration parameter doesn't apply to Aurora Serverless v2 DB instances.
- In the AWS Billing and Cost Management console, filtering by custom tags added to Aurora Serverless v2 shows zero usage. Use other filtering options, such as AWS Region, engine, and usageType, to get accurate billed values.

Some Aurora features work with Aurora Serverless v2, but might cause issues if your capacity range is lower than needed for the memory requirements for those features with your specific workload. In that case, your database might not perform as well as usual, or might encounter out-of-memory errors. For recommendations about setting the appropriate capacity range, see [Choosing the Aurora Serverless v2 capacity range for an Aurora cluster \(p. 1527\)](#). For troubleshooting information if your database encounters out-of-memory errors due to a misconfigured capacity range, see [Avoiding out-of-memory errors \(p. 1538\)](#).

Aurora Auto Scaling isn't supported. This type of scaling adds new readers to handle additional read-intensive workload, based on CPU utilization. However, scaling based on CPU utilization isn't meaningful for Aurora Serverless v2. As an alternative, you can create Aurora Serverless v2 reader DB instances in advance and leave them scaled down to low capacity. That's a faster and less disruptive way to scale a cluster's read capacity than adding new DB instances dynamically.

## Some Aurora Serverless v2 aspects are different from Aurora Serverless v1

If you are an Aurora Serverless v1 user and this is your first time using Aurora Serverless v2, consult [differences between Aurora Serverless v2 and Aurora Serverless v1 requirements \(p. 1500\)](#) to understand how requirements are different between Aurora Serverless v1 and Aurora Serverless v2.

## Getting started with Aurora Serverless v2

To convert an existing database to use Aurora Serverless v2, you can do the following:

- Upgrade from a provisioned Aurora cluster.
- Upgrade from an Aurora Serverless v1 cluster.
- Perform a dump and restore from an Aurora Serverless v2 (preview) cluster.
- Migrate from an on-premises database to an Aurora Serverless v2 cluster.

When your upgraded cluster is running the appropriate engine version as listed in [Requirements for Aurora Serverless v2 \(p. 1490\)](#), you can begin adding Aurora Serverless v2 DB instances to it. The first DB instance that you add to the upgraded cluster must be a provisioned DB instance. Then you can switch over the processing for the write workload, the read workload, or both to the Aurora Serverless v2 DB instances.

### Contents

    - Comparison of Aurora Serverless v2 and Aurora Serverless v1 feature support (p. 1503)
  - Adapting Aurora Serverless v1 use cases to Aurora Serverless v2 (p. 1504)
  - Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2 (p. 1505)
- [Upgrading from Aurora Serverless v2 \(preview\) to Aurora Serverless v2 \(p. 1506\)](#)
- [Migrating from an on-premises database to Aurora Serverless v2 \(p. 1506\)](#)

## Upgrading or switching existing clusters to use Aurora Serverless v2

If your provisioned cluster has an engine version that supports Aurora Serverless v2, switching to Aurora Serverless v2 doesn't require an upgrade. In that case, you can add Aurora Serverless v2 DB instances to your original cluster. You can switch the cluster to use all Aurora Serverless v2 DB instances. You can also use a combination of Aurora Serverless v2 and provisioned DB instances in the same DB cluster. For the

Aurora engine versions that support Aurora Serverless v2, see [Aurora Serverless v2 requires minimum engine versions \(p. 1490\)](#).

If you're running a lower engine version that doesn't support Aurora Serverless v2, you take these general steps:

1. Upgrade the cluster.
2. Create a provisioned writer DB instance for the upgraded cluster.
3. Modify the cluster to use Aurora Serverless v2 DB instances.

Such an upgrade might involve one or more snapshot restore operations. When doing an upgrade across multiple major engine versions, you perform an intermediate upgrade for every major version between the original and final clusters.

**Important**

When you perform a major version upgrade to an Aurora Serverless v2-compatible version by using snapshot restore or cloning, the first DB instance that you add to the new cluster must be a provisioned DB instance. This addition starts the final stage of the upgrade process.

Until that final stage happens, the cluster doesn't have the infrastructure that's required for Aurora Serverless v2 support. Thus, these upgraded clusters always start with a provisioned writer DB instance. Then you can convert or fail over the provisioned DB instance to an Aurora Serverless v2 one.

Upgrading from Aurora Serverless v1 to Aurora Serverless v2 involves creating a provisioned cluster as an intermediate step. Then you perform the same upgrade steps as when you start with a provisioned cluster.

Switching from Aurora Serverless v2 (preview) to Aurora Serverless v2 involves a logical dump and restore.

## Upgrade paths for MySQL-compatible clusters to use Aurora Serverless v2

If your original cluster is running Aurora MySQL, choose the appropriate procedure depending on the engine version and engine mode of your cluster.

If your original Aurora MySQL cluster is this	Do this to switch to Aurora Serverless v2
Provisioned cluster running Aurora MySQL version 3, compatible with MySQL 8.0	This is the final stage for all conversions from existing Aurora MySQL clusters.  If necessary, perform a minor version upgrade to version 3.02.0 or higher. Use a provisioned DB instance for the writer DB instance. Add one Aurora Serverless v2 reader DB instance. Perform a failover to make that the writer DB instance. Optional: Convert other provisioned DB instances in the cluster to Aurora Serverless v2, or add new Aurora Serverless v2 DB instances and remove the provisioned DB instances.  For the full procedure and examples, see <a href="#">Switching from a provisioned cluster to Aurora Serverless v2 (p. 1495)</a> .
Provisioned cluster running Aurora MySQL version 2, compatible with MySQL 5.7	Perform a major version upgrade to Aurora MySQL version 3.02.0 or higher. Then follow

If your original Aurora MySQL cluster is this	Do this to switch to Aurora Serverless v2
	the procedure for Aurora MySQL version 3 to switch the cluster to use Aurora Serverless v2 DB instances.
Provisioned cluster running Aurora MySQL version 1, compatible with MySQL 5.6	Perform an intermediate major version upgrade to Aurora MySQL version 2. Perform another major version upgrade to Aurora MySQL version 3.02.0 or higher. Then follow the procedure for Aurora MySQL version 3 to switch the cluster to use Aurora Serverless v2 DB instances.
Aurora Serverless v1 cluster running Aurora MySQL version 2, compatible with MySQL 5.7	To help plan your conversion from Aurora Serverless v1, consult <a href="#">Moving from Aurora Serverless v1 to Aurora Serverless v2 (p. 1499)</a> first.  Then follow the procedure in <a href="#">Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2 (p. 1505)</a> .
Aurora Serverless v1 cluster running Aurora MySQL version 1, compatible with MySQL 5.6	To help plan your conversion from Aurora Serverless v1, consult <a href="#">Moving from Aurora Serverless v1 to Aurora Serverless v2 (p. 1499)</a> first.  Then follow the procedure in <a href="#">Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2 (p. 1505)</a> .
Aurora Serverless v2 (preview) cluster	Perform a logical dump and restore to a provisioned cluster that's running the same engine version as the preview cluster. Then follow the procedure to upgrade from that version.

## Upgrade paths for PostgreSQL-compatible clusters to use Aurora Serverless v2

If your original cluster is running Aurora PostgreSQL, choose the appropriate procedure depending on the engine version and engine mode of your cluster.

If your original Aurora PostgreSQL cluster is this	Do this to switch to Aurora Serverless v2
Provisioned cluster running Aurora PostgreSQL version 13	This is the final stage for all conversions from existing Aurora PostgreSQL clusters.  If necessary, perform a minor version upgrade to version 13.6 or higher. Add one provisioned DB instance for the writer DB instance. Add one Aurora Serverless v2 reader DB instance. Perform a failover to make that Aurora Serverless v2 instance the writer DB instance. Optional: Convert other provisioned DB instances in the cluster to Aurora Serverless v2, or add new

If your original Aurora PostgreSQL cluster is this	Do this to switch to Aurora Serverless v2
	Aurora Serverless v2 DB instances and remove the provisioned DB instances.  For the full procedure and examples, see <a href="#">Switching from a provisioned cluster to Aurora Serverless v2 (p. 1495)</a> .
Provisioned cluster running Aurora PostgreSQL version 12	Perform a major version upgrade to Aurora PostgreSQL version 13.6 or higher. Then follow the procedure for Aurora PostgreSQL version 13 to switch the cluster to use Aurora Serverless v2 DB instances.
Provisioned cluster running Aurora PostgreSQL version 11	Perform an intermediate major version upgrade to each successive Aurora PostgreSQL major version until you reach Aurora PostgreSQL version 13.6 or higher. Depending on the starting version, you might be able to upgrade directly to the final Aurora PostgreSQL version. For details about which Aurora PostgreSQL versions can upgrade directly to which other Aurora PostgreSQL major versions, see <a href="#">How to perform a major version upgrade (p. 1417)</a> . Then follow the procedure for Aurora MySQL version 13 to switch the cluster to use Aurora Serverless v2 DB instances.
Provisioned cluster running Aurora PostgreSQL version 10	Perform an intermediate major version upgrade to each successive Aurora PostgreSQL major version until you reach Aurora PostgreSQL version 13.6 or higher. Depending on the starting version, you might be able to upgrade directly to the final Aurora PostgreSQL version. For details about which Aurora PostgreSQL versions can upgrade directly to which other Aurora PostgreSQL major versions, see <a href="#">How to perform a major version upgrade (p. 1417)</a> . Then follow the procedure for Aurora MySQL version 13 to switch the cluster to use Aurora Serverless v2 DB instances.
Aurora Serverless v1 cluster running Aurora PostgreSQL version 10 or 11	To help plan your conversion from Aurora Serverless v1, consult <a href="#">Moving from Aurora Serverless v1 to Aurora Serverless v2 (p. 1499)</a> first.  Then follow the procedure in <a href="#">Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2 (p. 1505)</a> .

## Switching from a provisioned cluster to Aurora Serverless v2

To switch a provisioned cluster to use Aurora Serverless v2, follow these steps:

1. Check if the provisioned cluster needs to be upgraded to be used with Aurora Serverless v2 DB instances. For the Aurora versions that are compatible with Aurora Serverless v2, see [Requirements for Aurora Serverless v2 \(p. 1490\)](#).

If the provisioned cluster is running an engine version that isn't available for Aurora Serverless v2, upgrade the engine version of the cluster:

- If you have a MySQL 5.6-compatible or MySQL 5.7-compatible provisioned cluster, follow the upgrade instructions for Aurora MySQL version 3. Use the procedures in [Upgrading to Aurora MySQL version 3 \(p. 666\)](#).
- If you have a PostgreSQL-compatible provisioned cluster running PostgreSQL version 10 through 12, follow the upgrade instructions for Aurora PostgreSQL version 13. Use the procedures in [How to perform a major version upgrade \(p. 1417\)](#).

2. Configure any other cluster properties to match the Aurora Serverless v2 requirements from [Requirements for Aurora Serverless v2 \(p. 1490\)](#).
3. Configure the scaling configuration for the cluster. Follow the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster \(p. 1510\)](#).
4. Add one or more Aurora Serverless v2 DB instances to the cluster. Follow the general procedure in [Adding Aurora Replicas to a DB cluster \(p. 270\)](#). For each new DB instance, specify the special DB instance class name **Serverless** in the AWS Management Console, or `db.serverless` in the AWS CLI or Amazon RDS API.

In some cases, you might already have one or more provisioned reader DB instances in the cluster. If so, you can convert one of the readers to an Aurora Serverless v2 DB instance instead of creating a new DB instance. To do so, follow the procedure in [Converting a provisioned writer or reader to Aurora Serverless v2 \(p. 1518\)](#).

5. Perform a failover operation to make one of the Aurora Serverless v2 DB instances the writer DB instance for the cluster.
6. (Optional) Convert any provisioned DB instances to Aurora Serverless v2, or remove them from the cluster. Follow the general procedure in [Converting a provisioned writer or reader to Aurora Serverless v2 \(p. 1518\)](#) or [Deleting a DB instance from an Aurora DB cluster \(p. 350\)](#).

**Tip**

Removing the provisioned DB instances isn't mandatory. You can set up a cluster containing both Aurora Serverless v2 and provisioned DB instances. However, until you are familiar with the performance and scaling characteristics of Aurora Serverless v2 DB instances, we recommend that you configure your clusters with DB instances all of the same type.

The following AWS CLI example shows the switchover process using a provisioned cluster that's running Aurora MySQL version 3.02.0. The cluster is named `mysql-80`. The cluster starts with two provisioned DB instances named `provisioned-instance-1` and `provisioned-instance-2`, a writer and a reader. They both use the `db.r6g.large` DB instance class.

```
$ aws rds describe-db-clusters --db-cluster-identifier mysql-80 \
  --query '*[].[DBClusterIdentifier,DBClusterMembers[*].
[DBInstanceIdentifier,IsClusterWriter]]' --output text
mysql-80
provisioned-instance-2      False
provisioned-instance-1      True

$ aws rds describe-db-instances --db-instance-identifier provisioned-instance-1 \
  --output text --query '*[].[DBInstanceIdentifier,DBInstanceClass]'
provisioned-instance-1      db.r6g.large

$ aws rds describe-db-instances --db-instance-identifier provisioned-instance-2 \
  --output text --query '*[].[DBInstanceIdentifier,DBInstanceClass]'
provisioned-instance-2      db.r6g.large
```

We create a table with some data. That way, we can confirm that the data and operation of the cluster are the same before and after the switchover.

```
mysql> create database serverless_v2_demo;
mysql> create table serverless_v2_demo.demo (s varchar(128));
mysql> insert into serverless_v2_demo.demo values ('This cluster started with a provisioned writer.');
Query OK, 1 row affected (0.02 sec)
```

First, we add a capacity range to the cluster. Otherwise, we get an error when adding any Aurora Serverless v2 DB instances to the cluster. If we use the AWS Management Console for this procedure, that step is automatic when we add the first Aurora Serverless v2 DB instance.

```
$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-1 \
--db-cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-mysql

An error occurred (InvalidDBClusterStateFault) when calling the CreateDBInstance operation:
Set the Serverless v2 scaling configuration on the parent DB cluster before creating a
Serverless v2 DB instance.

$ # The blank ServerlessV2ScalingConfiguration attribute confirms that the cluster doesn't
have a capacity range set yet.
$ aws rds describe-db-clusters --db-cluster-identifier mysql-80 --query
'DBClusters[*].ServerlessV2ScalingConfiguration'
[]

$ aws rds modify-db-cluster --db-cluster-identifier mysql-80 \
--serverless-v2-scaling-configuration MinCapacity=0.5,MaxCapacity=16
{
  "DBClusterIdentifier": "mysql-80",
  "ServerlessV2ScalingConfiguration": {
    "MinCapacity": 0.5,
    "MaxCapacity": 16
  }
}
```

We create two Aurora Serverless v2 readers to take the place of the original DB instances, by specifying the db.serverless DB instance class for the new DB instances.

```
$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-1 --db-
cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-mysql
{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "DBClusterIdentifier": "mysql-80",
  "DBInstanceClass": "db.serverless",
  "DBInstanceState": "creating"
}

$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-2 \
--db-cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-mysql
{
  "DBInstanceIdentifier": "serverless-v2-instance-2",
  "DBClusterIdentifier": "mysql-80",
  "DBInstanceClass": "db.serverless",
  "DBInstanceState": "creating"
}

$ # Wait for both DB instances to finish being created before proceeding.
$ aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1 && \
aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-2
```

We perform a failover to make one of the Aurora Serverless v2 DB instances the new writer for the cluster.

```
$ aws rds failover-db-cluster --db-cluster-identifier mysql-80 \
--target-db-instance-identifier serverless-v2-instance-1
{
  "DBClusterIdentifier": "mysql-80",
  "DBClusterMembers": [
    {
      "DBInstanceIdentifier": "serverless-v2-instance-1",
      "IsClusterWriter": false,
      "DBClusterParameterGroupStatus": "in-sync",
      "PromotionTier": 1
    },
    {
      "DBInstanceIdentifier": "serverless-v2-instance-2",
      "IsClusterWriter": false,
      "DBClusterParameterGroupStatus": "in-sync",
      "PromotionTier": 1
    },
    {
      "DBInstanceIdentifier": "provisioned-instance-2",
      "IsClusterWriter": false,
      "DBClusterParameterGroupStatus": "in-sync",
      "PromotionTier": 1
    },
    {
      "DBInstanceIdentifier": "provisioned-instance-1",
      "IsClusterWriter": true,
      "DBClusterParameterGroupStatus": "in-sync",
      "PromotionTier": 1
    }
  ],
  "Status": "available"
}
```

It takes a few seconds for that change to take effect. At that point, we have an Aurora Serverless v2 writer and an Aurora Serverless v2 reader. Thus, we don't need either of the original provisioned DB instances.

```
$ aws rds describe-db-clusters --db-cluster-identifier mysql-80 \
--query '*[].[DBClusterIdentifier,DBClusterMembers[*].
[DBInstanceIdentifier,IsClusterWriter]]' \
--output text
mysql-80
serverless-v2-instance-1      True
serverless-v2-instance-2      False
provisioned-instance-2       False
provisioned-instance-1       False
```

The last step in the switchover procedure is to delete both of the provisioned DB instances.

```
$ aws rds delete-db-instance --db-instance-identifier provisioned-instance-2 --skip-final-
snapshot
{
  "DBInstanceIdentifier": "provisioned-instance-2",
  "DBInstanceState": "deleting",
  "Engine": "aurora-mysql",
  "EngineVersion": "8.0.mysql_aurora.3.02.0",
  "DBInstanceClass": "db.r6g.large"
}
```

```
$ aws rds delete-db-instance --db-instance-identifier provisioned-instance-1 --skip-final-snapshot
{
    "DBInstanceIdentifier": "provisioned-instance-1",
    "DBInstanceState": "deleting",
    "Engine": "aurora-mysql",
    "EngineVersion": "8.0.mysql_aurora.3.02.0",
    "DBInstanceClass": "db.r6g.large"
}
```

As a final check, we confirm that the original table is accessible and writeable from the Aurora Serverless v2 writer DB instance.

```
mysql> select * from serverless_v2_demo.demo;
+-----+
| s |
+-----+
| This cluster started with a provisioned writer. |
+-----+
1 row in set (0.00 sec)

mysql> insert into serverless_v2_demo.demo values ('And it finished with a Serverless v2 writer.');
Query OK, 1 row affected (0.01 sec)

mysql> select * from serverless_v2_demo.demo;
+-----+
| s |
+-----+
| This cluster started with a provisioned writer. |
| And it finished with a Serverless v2 writer. |
+-----+
2 rows in set (0.01 sec)
```

We also connect to the Aurora Serverless v2 reader DB instance and confirm that the newly written data is available there too.

```
mysql> select * from serverless_v2_demo.demo;
+-----+
| s |
+-----+
| This cluster started with a provisioned writer. |
| And it finished with a Serverless v2 writer. |
+-----+
2 rows in set (0.01 sec)
```

## Moving from Aurora Serverless v1 to Aurora Serverless v2

If you are already using Aurora Serverless v1 and want to use Aurora Serverless v2, familiarize yourself with the differences first. Following, you can learn how Aurora Serverless v1 differs from Aurora Serverless v2. You can also learn how you can move your DB clusters and applications from one to the other.

### Topics

- [Comparison of Aurora Serverless v2 and Aurora Serverless v1 \(p. 1500\)](#)
- [Adapting Aurora Serverless v1 use cases to Aurora Serverless v2 \(p. 1504\)](#)

- [Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2 \(p. 1505\)](#)

## Comparison of Aurora Serverless v2 and Aurora Serverless v1

If you are already using Aurora Serverless v1, you can learn the major differences between Aurora Serverless v1 and Aurora Serverless v2. The architectural differences, such as support for reader DB instances, open up new types of use cases.

You can use the following tables to help understand the most important differences between Aurora Serverless v2 and Aurora Serverless v1.

### Topics

- [Comparison of Aurora Serverless v2 and Aurora Serverless v1 requirements \(p. 1500\)](#)
- [Comparison of Aurora Serverless v2 and Aurora Serverless v1 scaling and availability \(p. 1501\)](#)
- [Comparison of Aurora Serverless v2 and Aurora Serverless v1 feature support \(p. 1503\)](#)

### Comparison of Aurora Serverless v2 and Aurora Serverless v1 requirements

The following table summarizes the different requirements to run your database using Aurora Serverless v2 or Aurora Serverless v1. Aurora Serverless v2 offers higher versions of the Aurora MySQL and Aurora PostgreSQL DB engines than Aurora Serverless v1 does.

Feature	Aurora Serverless v2 requirement	Aurora Serverless v1 requirement
DB engines	Aurora MySQL, Aurora PostgreSQL	Aurora MySQL, Aurora PostgreSQL
Supported Aurora MySQL versions	Version 3.02.0, compatible with MySQL 8.0	Versions 1 and 2, compatible with MySQL 5.6 and 5.7
Supported Aurora PostgreSQL versions	Version 13.6, 13.7, or 14.3	Version 10.18 or 11.13
Converting from provisioned DB cluster	<p>You can use the following methods:</p> <ul style="list-style-type: none"><li>• Add one or more Aurora Serverless v2 reader DB instances to an existing provisioned cluster. To use Aurora Serverless v2 for the writer, perform a failover to one of the Aurora Serverless v2 DB instances. For the entire cluster to use Aurora Serverless v2 DB instances, remove any provisioned writer DB instances after promoting the Aurora Serverless v2 DB instance to the writer.</li><li>• Create a new cluster with the appropriate DB engine and engine version. Use any of the standard methods. For example, restore a cluster snapshot or create a clone of an existing cluster. Choose Aurora Serverless v2 for some or</li></ul>	Restore snapshot of provisioned cluster to create new Aurora Serverless v1 cluster.

Feature	Aurora Serverless v2 requirement	Aurora Serverless v1 requirement
	<p>all of the DB instances in the new cluster.</p> <p>If you create the new cluster through cloning, you can't upgrade the engine version at the same time. Make sure that the original cluster is already running an engine version that's compatible with Aurora Serverless v2.</p>	
Converting from Aurora Serverless v1 cluster	Follow the procedure in <a href="#">Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2 (p. 1505)</a> .	Not applicable
Available DB instance classes	The special DB instance class <code>db.serverless</code> . In the AWS Management Console, it's labeled as <b>Serverless</b> .	Not applicable.
Port	Any port that's compatible with MySQL or PostgreSQL	Default MySQL or PostgreSQL port only
Public IP address allowed?	Yes	No
Virtual private cloud (VPC) required?	Yes	Yes. Each Aurora Serverless v1 cluster consumes 2 interface and Gateway Load Balancer endpoints allocated to your VPC.

## Comparison of Aurora Serverless v2 and Aurora Serverless v1 scaling and availability

The following table summarizes differences between Aurora Serverless v2 and Aurora Serverless v1 for scalability and availability.

Aurora Serverless v2 scaling is more responsive, more granular, and less disruptive than the scaling in Aurora Serverless v1. Aurora Serverless v2 can scale both by changing the size of the DB instance and by adding more DB instances to the DB cluster. It can also scale by adding clusters in other AWS Regions to an Aurora global database. In contrast, Aurora Serverless v1 only scales by increasing or decreasing the capacity of the writer. All the compute for an Aurora Serverless v1 cluster runs in a single Availability Zone and a single AWS Region.

Feature	Aurora Serverless v2 scaling and high availability behavior	Aurora Serverless v1 scaling and high availability behavior
Minimum Aurora capacity units (ACUs) (Aurora MySQL)	0.5	1 when the cluster is running, 0 when the cluster is paused.
Minimum ACUs (Aurora PostgreSQL)	0.5	2 when the cluster is running, 0 when the cluster is paused.
Maximum ACUs (Aurora MySQL)	128	256

Feature	Aurora Serverless v2 scaling and high availability behavior	Aurora Serverless v1 scaling and high availability behavior
Maximum ACUs (Aurora PostgreSQL)	128	384
Stopping a cluster	You can manually stop and start the cluster by using <a href="#">the same cluster stop and start feature</a> as provisioned clusters.	The cluster pauses automatically after a timeout. It takes some time to become available when activity resumes.
Scaling for DB instances	Scale up and down with minimum increment of 0.5 ACUs	Scale up and down by doubling or halving the ACUs
Number of DB instances	Same as a provisioned cluster: 1 writer DB instance, up to 15 reader DB instances.	1 DB instance handling both reads and writes.
Scaling can happen while SQL statements are running?	Yes. Aurora Serverless v2 doesn't require waiting for a quiet point.	No. For example, scaling waits for completion of long-running transactions, temporary tables, and table locks.
Reader DB instances scale along with writer	Optional.	Not applicable.
Maximum storage	128 TiB	128 TiB or 64 TiB, depending on database engine and version.
Buffer cache preserved when scaling	Yes. Buffer cache is resized dynamically.	No. Buffer cache is rewarmed after scaling.
Failover	Yes, same as for provisioned clusters.	Best effort only, subject to capacity availability. Slower than in Aurora Serverless v2.
Multi-AZ capability	Yes, same as for provisioned. A Multi-AZ cluster requires a reader DB instance in a second Availability Zone (AZ). For a Multi-AZ cluster, Aurora performs Multi-AZ failover in case of an AZ failure.	Aurora Serverless v1 clusters run all their compute in a single AZ. Recovery in case of AZ failure is best effort only and subject to capacity availability.
Aurora global databases	Yes	No
Scaling based on memory pressure	Yes	No
Scaling based on CPU load	Yes	Yes
Scaling based on network traffic	Yes, based on memory and CPU overhead of network traffic. The <code>max_connections</code> parameter remains constant to avoid dropping connections when scaling down.	Yes, based on number of connections.
Timeout action for scaling events	No	Yes

Feature	Aurora Serverless v2 scaling and high availability behavior	Aurora Serverless v1 scaling and high availability behavior
Adding new DB instances to cluster through AWS Auto Scaling	Not applicable. You can create Aurora Serverless v2 reader DB instances in promotion tiers 2–15 and leave them scaled down to low capacity.	No. Reader DB instances aren't available.

## Comparison of Aurora Serverless v2 and Aurora Serverless v1 feature support

The following table summarizes these:

- Features that are available in Aurora Serverless v2 but not Aurora Serverless v1
- Features that work differently between Aurora Serverless v1 and Aurora Serverless v2
- Features that aren't currently available in Aurora Serverless v2

Aurora Serverless v2 includes many features from provisioned clusters that aren't available for Aurora Serverless v1.

Feature	Aurora Serverless v2 features	Aurora Serverless v1 features
Cluster topology	Aurora Serverless v2 is a property of individual DB instances. A cluster can contain multiple Aurora Serverless v2 DB instances, or a combination of Aurora Serverless v2 and provisioned DB instances.	Aurora Serverless v1 clusters don't use the notion of DB instances. You can't change the Aurora Serverless v1 property after you create the cluster.
Configuration parameters	Almost all the same parameters can be modified as in provisioned clusters. For details, see <a href="#">Working with parameter groups for Aurora Serverless v2 (p. 1535)</a> .	Only a subset of parameters can be modified.
Parameter groups	Cluster parameter group and DB parameter groups. Parameters with provisioned value in <code>SupportedEngineModes</code> attribute are available. That's many more parameters than in Aurora Serverless v1.	Cluster parameter group only. Parameters with <code>serverless</code> value in <code>SupportedEngineModes</code> attribute are available.
Encryption for cluster volume	Optional.	Required. The limitations in <a href="#">Limitations of Amazon Aurora encrypted DB clusters (p. 1640)</a> apply to all Aurora Serverless v1 clusters.
Cross-Region snapshots	Yes	Snapshot must be encrypted with your own AWS Key Management Service (AWS KMS) key.
TLS/SSL	Yes. The support is the same as for provisioned clusters. For usage	Yes. There are some differences from TLS support for provisioned clusters.

Feature	Aurora Serverless v2 features	Aurora Serverless v1 features
	information, see <a href="#">Using TLS/SSL with Aurora Serverless v2 (p. 1521)</a> .	For usage information, see <a href="#">Using TLS/SSL with Aurora Serverless v1 (p. 1546)</a> .
Cloning	Only from and to DB engine versions that are compatible with Aurora Serverless v2. You can't use cloning to upgrade from Aurora Serverless v1 or from an earlier version of a provisioned cluster.	Only from and to DB engine versions that are compatible with Aurora Serverless v1.
Integration with Amazon S3	Yes	Yes
Exporting DB cluster snapshots to S3	Yes	No
Associating an IAM role	Yes	No
Uploading logs to Amazon CloudWatch	Optional. You choose which logs to turn on and which logs to upload to CloudWatch.	All logs that are turned on are uploaded to CloudWatch automatically.
Data API available	No	Yes
Query editor available	No	Yes
Performance Insights	Yes	No
Amazon RDS Proxy available	Yes	No
Babelfish for Aurora PostgreSQL available	Yes. Supported for Aurora PostgreSQL versions that are compatible with both Babelfish and Aurora Serverless v2.	No

## Adapting Aurora Serverless v1 use cases to Aurora Serverless v2

Depending on your use case for Aurora Serverless v1, you might adapt that approach to take advantage of Aurora Serverless v2 features as follows.

Suppose that you have an Aurora Serverless v1 cluster that is lightly loaded and your priority is maintaining continuous availability while minimizing costs. With Aurora Serverless v2, you can configure a smaller minimum ACU setting of 0.5, compared with a minimum of 1 ACU for Aurora Serverless v1. You can increase availability by creating a Multi-AZ configuration, with the reader DB instance also having a minimum of 0.5 ACUs.

Suppose that you have an Aurora Serverless v1 cluster that you use in a development and test scenario. In this case, cost is also a high priority but the cluster doesn't need to be available at all times. Currently, Aurora Serverless v2 doesn't automatically pause when the cluster is completely idle. Instead, you can manually stop the cluster when it's not needed, and start it when it's time for the next test or development cycle.

Suppose that you have an Aurora Serverless v1 cluster with a heavy workload. An equivalent cluster using Aurora Serverless v2 can scale with more granularity. For example, Aurora Serverless v1 scales by doubling the capacity, for example from 64 to 128 ACUs. In contrast, your Aurora Serverless v2 DB instance can scale to a value somewhere between those numbers.

Suppose that your workload requires a higher total capacity than is available in Aurora Serverless v1. You can use multiple Aurora Serverless v2 reader DB instances to offload the read-intensive parts of the workload from the writer DB instance. You can also divide the read-intensive workload among multiple reader DB instances.

For a write-intensive workload, you might configure the cluster with a large provisioned DB instance as the writer, alongside one or more Aurora Serverless v2 reader DB instances.

## Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2

The process of upgrading a DB cluster from Aurora Serverless v1 to Aurora Serverless v2 involves several steps. That's because Aurora Serverless v1 isn't available for the same major Aurora MySQL and Aurora PostgreSQL versions as Aurora Serverless v2 is. Thus, going from Aurora Serverless v1 to Aurora Serverless v2 always involves at least one major version upgrade.

### To upgrade an Aurora Serverless v1 cluster running Aurora MySQL version 2 (MySQL 5.7–compatible)

1. Create a DB cluster snapshot of the Aurora Serverless v1 cluster. Follow the procedure in [Creating a DB cluster snapshot \(p. 373\)](#).
2. Restore the snapshot to create a new, provisioned (that is, *not* Aurora Serverless) DB cluster running Aurora MySQL version 2. Follow the procedure in [Restoring from a DB cluster snapshot \(p. 375\)](#).  
Choose the latest minor engine version available for the new cluster, for example, 2.10.2.
3. Create a DB cluster snapshot of the provisioned Aurora MySQL version 2 cluster.
4. Restore the snapshot to create a new, provisioned DB cluster running Aurora MySQL version 3 that's compatible with Aurora Serverless v2, for example, 3.02.0.  
For compatible versions, see [Aurora Serverless v2 \(p. 31\)](#).
5. Modify the writer DB instance of the provisioned DB cluster to use the **Serverless v2** DB instance class.

For details, see [Converting a provisioned writer or reader to Aurora Serverless v2 \(p. 1518\)](#).

### To upgrade an Aurora Serverless v1 cluster running Aurora MySQL version 1 (MySQL 5.6–compatible)

1. Perform an in-place upgrade of the Aurora Serverless v1 cluster. Follow the procedure in [Modifying an Aurora Serverless v1 DB cluster \(p. 1570\)](#).
2. Follow the steps in the previous procedure for upgrading from an Aurora Serverless v1 DB cluster running Aurora MySQL version 2.

### To upgrade an Aurora Serverless v1 cluster running Aurora PostgreSQL

1. Create a DB cluster snapshot of the Aurora Serverless v1 cluster. Follow the procedure in [Creating a DB cluster snapshot \(p. 373\)](#).
2. Restore the snapshot to create a new, provisioned (that is, *not* Aurora Serverless) DB cluster. Follow the procedure in [Restoring from a DB cluster snapshot \(p. 375\)](#).  
Choose the latest minor engine version available for the new cluster, for example, 10.21.
3. Modify the provisioned DB cluster to upgrade it to an Aurora PostgreSQL version that's compatible with Aurora Serverless v2, for example, 13.7.

Follow the procedure in [Upgrading the Aurora PostgreSQL engine to a new major version \(p. 1422\)](#). For compatible versions, see [Aurora Serverless v2 \(p. 31\)](#).

4. Modify the writer DB instance of the provisioned DB cluster to use the **Serverless v2** DB instance class.

For details, see [Converting a provisioned writer or reader to Aurora Serverless v2 \(p. 1518\)](#).

## Upgrading from Aurora Serverless v2 (preview) to Aurora Serverless v2

Any Aurora MySQL clusters that you created using the Aurora Serverless v2 preview can't be upgraded using the snapshot restore mechanism. The preview is intended for testing only. Your preview clusters shouldn't contain any production or business-critical data. If you need to bring any data from an Aurora Serverless v2 preview cluster to Aurora Serverless v2, perform a logical dump and restore. Use the `mysqldump` command as described in [Migrating from MySQL to Amazon Aurora by using mysqldump \(p. 705\)](#).

## Migrating from an on-premises database to Aurora Serverless v2

You can migrate your on-premises databases to Aurora Serverless v2, just as with provisioned Aurora MySQL and Aurora PostgreSQL.

- For MySQL databases, you can use the `mysqldump` command. For more information, see [Importing data to a MySQL or MariaDB DB instance with reduced downtime](#).
- For PostgreSQL databases, you can use the `pg_dump` and `pg_restore` commands. For more information, see the blog post [Best practices for migrating PostgreSQL databases to Amazon RDS and Amazon Aurora](#).

## Creating a cluster that uses Aurora Serverless v2

To create an Aurora cluster where you can add Aurora Serverless v2 DB instances, you follow the same procedure as in [Creating an Amazon Aurora DB cluster \(p. 127\)](#). With Aurora Serverless v2, your clusters are interchangeable with provisioned clusters. You can have clusters where some DB instances use Aurora Serverless v2 and some DB instances are provisioned.

If you intend to use Aurora Serverless v2 DB instances in a cluster, make sure that the cluster's initial settings meet the requirements that are listed in [Requirements for Aurora Serverless v2 \(p. 1490\)](#). Specify the following settings to make sure that you can add Aurora Serverless v2 DB instances to the cluster:

### AWS Region

Create the cluster in an AWS Region where Aurora Serverless v2 DB instances are available. For details about available Regions, see [Aurora Serverless v2 \(p. 31\)](#).

### DB engine version

Choose an engine version that's compatible with Aurora Serverless v2. For information about the Aurora Serverless v2 version requirements, see [Requirements for Aurora Serverless v2 \(p. 1490\)](#). On

the **Create database** page in the AWS Management Console, you can choose the filter setting **Show versions that support Serverless v2**. You can also see the applicable versions in the **Info** panel on the **Create database** page.

#### DB instance class

If you create a cluster using the AWS Management Console, you choose the DB instance class for the writer DB instance at the same time. Choose the **Serverless** DB instance class. When you choose that DB instance class, you also specify the capacity range for the writer DB instance. That same capacity range applies to all other Aurora Serverless v2 DB instances that you add to that cluster. If you don't see the **Serverless** choice for the DB instance class, make sure that you chose a DB engine version that's compatible with Aurora Serverless v2.

When you use the AWS CLI or the Amazon RDS API, the parameter that you specify for the DB instance class parameter is `db.serverless`.

#### capacity range

Fill in the minimum and maximum Aurora capacity unit (ACU) values that apply to all the DB instances in the cluster. This option is available on both the **Create cluster** and **Add reader** console pages when you choose **Serverless** for the DB instance class.

If you don't see the minimum and maximum ACU boxes, make sure that you chose the **Serverless** DB instance class for the writer DB instance.

#### Tip

A simple way to set up a new cluster where you can use Aurora Serverless v2 is to choose the **Easy create** setting on the console **Create database** page. With that setting, you only make a single other choice: whether the cluster is intended for development and test use or for production. Both of those options set up a cluster with an Aurora Serverless v2 writer DB instance.

If you initially create the cluster with a provisioned DB instance, you don't specify the minimum and maximum ACUs. In that case you can modify the cluster afterward to add that setting. You can also add an Aurora Serverless v2 reader DB instance to the cluster. You specify the capacity range as part of that process.

Until you specify the capacity range for your cluster, you can't add any Aurora Serverless v2 DB instances to the cluster using the AWS CLI or RDS API. If you try to add a Aurora Serverless v2 DB instance, you get an error. In the AWS CLI or the RDS API procedures, the capacity range is represented by the `ServerlessV2ScalingConfiguration` attribute.

For clusters containing more than one reader DB instance, the failover priority of each Aurora Serverless v2 reader DB instance plays an important part in how that DB instance scales up and down. You can't specify the priority when you initially create the cluster. Keep this property in mind when you add a second or later reader DB instance to your cluster. For more information, see [Choosing the promotion tier for an Aurora Serverless v2 reader \(p. 1521\)](#).

## Console

### To create a cluster with an Aurora Serverless v2 writer

1. Sign in using the AWS Management Console and open the Amazon RDS console.
2. Choose **Create Database**. On the page that appears, choose the following options:
  - For **Engine type**, choose Aurora.
  - For **Edition**, choose Aurora MySQL or Aurora PostgreSQL.

- For **Version**, choose one of the compatible versions from [Aurora Serverless v2 \(p. 31\)](#). To see the available versions, choose the filter **Show versions that support Serverless v2**.
- For **Capacity settings**, you can accept the default range. Or you can choose other values for minimum and maximum capacity units. You can choose from 0.5 ACUs minimum through 128 ACUs maximum, in increments of 0.5 ACU.

For more information about Aurora Serverless v2 capacity units, see [Aurora Serverless v2 capacity \(p. 1486\)](#) and [Performance and scaling for Aurora Serverless v2 \(p. 1526\)](#).

Capacity range [Info](#)  
Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum	Maximum
<input type="text" value="1"/> ACUs (2 GiB)	<input type="text" value="64"/> ACUs (128 GiB)
0.5 to 128 in increments of 0.5	0.5 to 128 in increments of 0.5

- Choose any other cluster settings, as described in [Creating an Amazon Aurora DB cluster \(p. 127\)](#).
- Choose **Create database** to create your Aurora cluster with an Aurora Serverless v2 DB instance as the writer instance, also known as the primary DB instance.

## CLI

To create a DB cluster that's compatible with Aurora Serverless v2 DB instances using the AWS CLI, you follow the CLI procedure in [Creating an Amazon Aurora DB cluster \(p. 127\)](#). Include the following parameters in your `create-db-cluster` command:

- `--region AWS_Region_where_Aurora_Serverless_v2_instances_are_available`
- `--engine-version serverless_v2_compatible_engine_version`
- `--serverless-v2-scaling-configuration MinCapacity=minimum_capacity,MaxCapacity=maximum_capacity`

The following example shows the creation of an Aurora Serverless v2 DB cluster.

```
aws rds create-db-cluster \
  --db-cluster-identifier my-serverless-v2-cluster \
  --region eu-central-1 \
  --engine aurora-mysql \
  --engine-version 8.0.mysql_aurora.3.02.0 \
  --serverless-v2-scaling-configuration MinCapacity=1,MaxCapacity=4 \
  --master-username myuser \
  --master-user-password mypassword \
  --backup-retention 1
```

### Note

When you create an Aurora Serverless v2 DB cluster using the AWS CLI, the engine mode appears in the output as provisioned rather than serverless. The serverless engine mode refers to Aurora Serverless v1.

For information about the Aurora Serverless v2 version requirements, see [Requirements for Aurora Serverless v2 \(p. 1490\)](#). For information about the allowed numbers for the capacity range and what those numbers represent, see [Aurora Serverless v2 capacity \(p. 1486\)](#) and [Performance and scaling for Aurora Serverless v2 \(p. 1526\)](#).

To verify whether an existing cluster has the capacity settings specified, check the output of the `describe-db-clusters` command for the `ServerlessV2ScalingConfiguration` attribute. That attribute looks similar to the following.

```
"ServerlessV2ScalingConfiguration": {  
    "MinCapacity": 1.5,  
    "MaxCapacity": 24.0  
}
```

**Tip**

If you don't specify the minimum and maximum ACUs when you create the cluster, you can use the `modify-db-cluster` command afterward to add that setting. Until you do, you can't add any Aurora Serverless v2 DB instances to the cluster. If you try to add a `db.serverless` DB instance, you get an error.

## API

To create a DB cluster that's compatible with Aurora Serverless v2 DB instances using the RDS API, you follow the API procedure in [Creating an Amazon Aurora DB cluster \(p. 127\)](#). Choose the following settings. Make sure that your `CreateDBCluster` operation includes the following parameters:

```
EngineVersion serverless_v2_compatible_engine_version  
ServerlessV2ScalingConfiguration with MinCapacity=minimum_capacity and  
MaxCapacity=maximum_capacity
```

For information about the Aurora Serverless v2 version requirements, see [Requirements for Aurora Serverless v2 \(p. 1490\)](#). For information about the allowed numbers for the capacity range and what those numbers represent, see [Aurora Serverless v2 capacity \(p. 1486\)](#) and [Performance and scaling for Aurora Serverless v2 \(p. 1526\)](#).

To check if an existing cluster has the capacity settings specified, check the output of the `DescribeDBClusters` operation for the `ServerlessV2ScalingConfiguration` attribute. That attribute looks similar to the following.

```
"ServerlessV2ScalingConfiguration": {  
    "MinCapacity": 1.5,  
    "MaxCapacity": 24.0  
}
```

**Tip**

If you don't specify the minimum and maximum ACUs when you create the cluster, you can use the `ModifyDBCluster` operation afterward to add that setting. Until you do, you can't add any Aurora Serverless v2 DB instances to the cluster. If you try to add a `db.serverless` DB instance, you get an error.

# Managing Aurora Serverless v2

With Aurora Serverless v2, your clusters are interchangeable with provisioned clusters. The Aurora Serverless v2 properties apply to one or more DB instances within a cluster. Thus, the procedures for creating clusters, modifying clusters, creating and restoring snapshots, and so on, are basically the same as for other kinds of Aurora clusters. For general procedures for managing Aurora clusters and DB instances, see [Managing an Amazon Aurora DB cluster \(p. 243\)](#).

Following, you can learn about management considerations for clusters that contain Aurora Serverless v2 DB instances.

## Setting the Aurora Serverless v2 capacity range for a cluster

To modify configuration parameters or other settings for clusters containing Aurora Serverless v2 DB instances, or the DB instances themselves, follow the same general procedures as for provisioned clusters. For details, see [Modifying an Amazon Aurora DB cluster \(p. 248\)](#).

The most important setting that's unique to Aurora Serverless v2 is the capacity range. After you set the minimum and maximum Aurora capacity unit (ACU) values for an Aurora cluster, you don't need to actively adjust the capacity of the Aurora Serverless v2 DB instances in the cluster. Aurora does that for you. This setting is managed at the cluster level. The same minimum and maximum ACU values apply to each Aurora Serverless v2 DB instance in the cluster.

You can set the following specific values:

- **Minimum ACUs** – The Aurora Serverless v2 DB instance can reduce capacity down to this number of ACUs.
- **Maximum ACUs** – The Aurora Serverless v2 DB instance can increase capacity up to this number of ACUs.

For details about the effects of the capacity range and how to monitor and fine-tune it, see [Important Amazon CloudWatch metrics for Aurora Serverless v2 \(p. 1539\)](#) and [Performance and scaling for Aurora Serverless v2 \(p. 1526\)](#). Your goal is to make sure that the maximum capacity for the cluster is high enough to handle spikes in workload, and the minimum is low enough to minimize costs when the cluster isn't busy.

Suppose that you determine based on your monitoring that the ACU range for the cluster should be higher, lower, wider, or narrower. You can set the capacity of an Aurora cluster to a specific range of ACUs with the AWS Management Console, the AWS CLI, or the Amazon RDS API. This capacity range applies to every Aurora Serverless v2 DB instance in the cluster.

For example, suppose that your cluster has a capacity range of 1–16 ACUs and contains two Aurora Serverless v2 DB instances. Then the cluster as a whole consumes somewhere between 2 ACUs (when idle) and 32 ACUs (when fully utilized). If you change the capacity range from 8 to 20.5 ACUs, now the cluster consumes 16 ACUs when idle, and up to 41 ACUs when fully utilized.

Aurora automatically sets certain parameters for Aurora Serverless v2 DB instances to values that depend on the maximum ACU value in the capacity range. For the list of such parameters, see [Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity \(p. 1537\)](#). For static parameters that rely on this type of calculation, the value is evaluated again when you reboot the DB

instance. Thus, you can update the value of such parameters by rebooting the DB instance after changing the capacity range. To check whether you need to reboot your DB instance to pick up such parameter changes, check the `ParameterApplyStatus` attribute of the DB instance. A value of `pending-reboot` indicates that rebooting will apply changes to some parameter values.

## Console

You can set the capacity range of a cluster that contains Aurora Serverless v2 DB instances with the AWS Management Console.

When you use the console, you set the capacity range for the cluster at the time that you add the first Aurora Serverless v2 DB instance to that cluster. You might do so when you choose the **Serverless v2** DB instance class for the writer DB instance when you create the cluster. Or you might do so when you choose the **Serverless** DB instance class when you add an Aurora Serverless v2 reader DB instance to the cluster. Or you might do so when you convert an existing provisioned DB instance in the cluster to the **Serverless** DB instance class. For the full versions of those procedures, see [Creating an Aurora Serverless v2 writer \(p. 1515\)](#), [Adding an Aurora Serverless v2 reader \(p. 1517\)](#), and [Converting a provisioned writer or reader to Aurora Serverless v2 \(p. 1518\)](#)

Whatever capacity range that you set at the cluster level applies to all Aurora Serverless v2 DB instances in your cluster. The following image shows a cluster with multiple Aurora Serverless v2 reader DB instances. Each has an identical capacity range of 2–64 ACUs.

Databases					
<input type="text"/> Filter by databases					
DB identifier	Role	Engine	Engine version	Region & AZ	
serverless-v2-cluster	Regional cluster	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1	
serverless-v2-cluster-reader-1	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	
serverless-v2-cluster-reader-2	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	
serverless-v2-cluster-instance-1	Writer instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	

## To modify the capacity range of an Aurora Serverless v2 cluster

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the cluster containing your Aurora Serverless v2 DB instances from the list. The cluster must already contain at least one Aurora Serverless v2 DB instance. Otherwise, Aurora doesn't show the **Capacity range** section.
4. For **Actions**, choose **Modify**.
5. In the **Capacity range** section, choose the following:
  - a. Enter a value for **Minimum ACUs**. The console shows the allowed range of values. You can choose from 0.5 ACUs minimum to 128 ACUs maximum, in increments of 0.5 ACU.
  - b. Enter a value for **Maximum ACUs**. This value must be greater than or equal to **Minimum ACUs**. The console shows the allowed range of values. The following screenshot shows that choice.

## Serverless v2 capacity settings

### Capacity range Info

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and 1 GiB of networking.

Minimum ACUs

2

(4 GiB)

0.5 to 128 in increments of 0.5

Maximum ACUs

64

(128 GiB)

0.5 to 128 in increments of 0.5

 The capacity range applies to all Serverless v2 instances in your cluster, including `serverless-v2-another-reader`, `serverless-v2-reader`.

6. Choose **Continue**. The **Summary of modifications** page appears.
7. Choose whether to apply the capacity change immediately, or during the next scheduled maintenance window.
8. Choose **Modify cluster** to accept the summary of modifications. You can also choose **Back** to modify your changes or **Cancel** to discard your changes.

### AWS CLI

To set the capacity of a cluster where you intend to use Aurora Serverless v2 DB instances using the AWS CLI, run the `modify-db-cluster` AWS CLI command. Specify the `--serverless-v2-scaling-configuration` option. The cluster might already contain one or more Aurora Serverless v2 DB instances, or you can add the DB instances later. Valid values for the `MinCapacity` and `MaxCapacity` fields include the following:

- 0.5, 1, 1.5, 2, and so on, in steps of 0.5, up to a maximum of 128.

In this example, you set the ACU range of an Aurora DB cluster named `sample-cluster` to a minimum of 48.5 and a maximum of 64.

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster --serverless-v2-scaling-configuration MinCapacity=48.5,MaxCapacity=64
```

After doing so, you can add Aurora Serverless v2 DB instances to the cluster and each new DB instance can scale between 48.5 and 64 ACUs. The new capacity range also applies to any Aurora Serverless v2 DB instances that were already in the cluster. The DB instances scale up or down if necessary to fall within the new capacity range.

For additional examples of setting the capacity range using the CLI, see [Choosing the Aurora Serverless v2 capacity range for an Aurora cluster \(p. 1527\)](#).

To modify the scaling configuration of an Aurora Serverless DB cluster using the AWS CLI, run the [modify-db-cluster](#) AWS CLI command. Specify the `--serverless-v2-scaling-configuration` option to configure the minimum capacity and maximum capacity. Valid capacity values include the following:

- Aurora MySQL: 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 128.
- Aurora PostgreSQL: 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 128.

In the following example, you modify the scaling configuration of an Aurora Serverless v2 DB instance named `sample-instance` that's part of a cluster named `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster \
--serverless-v2-scaling-configuration MinCapacity=8,MaxCapacity=64
```

For Windows:

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster ^
--serverless-v2-scaling-configuration MinCapacity=8,MaxCapacity=64
```

## RDS API

You can set the capacity of an Aurora DB instance with the [ModifyDBCluster](#) API operation. Specify the `ServerlessV2ScalingConfiguration` parameter. Valid values for the `MinCapacity` and `MaxCapacity` fields include the following:

- 0.5, 1, 1.5, 2, and so on, in steps of 0.5, up to a maximum of 128.

You can modify the scaling configuration of a cluster containing Aurora Serverless v2 DB instances with the [ModifyDBCluster](#) API operation. Specify the `ServerlessV2ScalingConfiguration` parameter to configure the minimum capacity and the maximum capacity. Valid capacity values include the following:

- Aurora MySQL: 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 128.
- Aurora PostgreSQL: 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 128.

## Checking the capacity range for Aurora Serverless v2

The procedure to check the capacity range for your Aurora Serverless v2 cluster requires that you first set a capacity range. If you haven't done so, follow the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster \(p. 1510\)](#).

Whatever capacity range you set at the cluster level applies to all Aurora Serverless v2 DB instances in your cluster. The following image shows a cluster with multiple Aurora Serverless v2 DB instances. Each has an identical capacity range.

Databases					
<input type="text"/> Filter by databases					
DB identifier	Role	Engine	Engine version	Region & AZ	
serverless-v2-cluster	Regional cluster	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1	
serverless-v2-cluster-reader-1	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	
serverless-v2-cluster-reader-2	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	
serverless-v2-cluster-instance-1	Writer instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	

You can also view the details page for any Aurora Serverless v2 DB instance in the cluster. DB instances' capacity range appears on the **Configuration** tab.

## Instance configuration

Instance type

Serverless v2

Minimum capacity

2 ACUs (4 GiB)

Maximum capacity

64 ACUs (128 GiB)

You can also see the current capacity range for the cluster on the **Modify** page for the cluster. The following image shows how. At that point, you can change the capacity range. For all the ways that you can set or change the capacity range, see [Setting the Aurora Serverless v2 capacity range for a cluster \(p. 1510\)](#).

## Serverless v2 capacity settings

### Capacity range [Info](#)

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and networking.

Minimum ACUs

2

(4 GiB)

0.5 to 128 in increments of 0.5

Maximum ACUs

64

(128 GiB)

0.5 to 128 in increments of 0.5

 The capacity range applies to all Serverless v2 instances in your cluster. Any existing reader instances, such as serverless-v2-another-reader,serverless-v2-reader, will inherit the capacity range.

## Checking the current capacity range for an Aurora cluster

You can check the capacity range that's configured for Aurora Serverless v2 DB instances in a cluster by examining the `ServerlessV2ScalingConfiguration` attribute for the cluster. The following AWS CLI example shows a cluster with a minimum capacity of 0.5 Aurora capacity units (ACUs) and a maximum capacity of 16 ACUs.

```
$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-64-acu-cluster \
--query 'DBClusters[*].[ServerlessV2ScalingConfiguration]'
[
  [
    {
      "MinCapacity": 0.5,
      "MaxCapacity": 16.0
    }
  ]
]
```

## Creating an Aurora Serverless v2 writer

### Console

When you create a cluster using the AWS Management Console, you specify the properties of the writer DB instance at the same time. To make the writer DB instance use Aurora Serverless v2, choose the **Serverless** DB instance class. Then you set the capacity range for the cluster by specifying the minimum and maximum Aurora capacity unit (ACU) values. These minimum and maximum values apply to each Aurora Serverless v2 DB instance in the cluster.

## Instance configuration

The DB instance configuration options below are limited to those supported by the engine.

### DB instance class [Info](#)

- Serverless v2
- Memory optimized classes (includes r classes)
- Burstable classes (includes t classes)

### Capacity range [Info](#)

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and 1 GiB of networking.

#### Minimum ACUs

4.5  (8 GiB)

0.5 to 128 in increments of 0.5

#### Maximum ACUs

16  (32 GiB)

0.5 to 128 in increments of 0.5

If you don't create an Aurora Serverless v2 DB instance when you first create the cluster, you can add one or more Aurora Serverless v2 DB instances later. To do so, follow the procedures in [Adding an Aurora Serverless v2 reader \(p. 1517\)](#) and [Converting a provisioned writer or reader to Aurora Serverless v2 \(p. 1518\)](#). You specify the capacity range at the time that you add the first Aurora Serverless v2 DB instance to the cluster. You can change the capacity range later by following the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster \(p. 1510\)](#).

### CLI

When you create a Aurora Serverless v2 DB cluster using the AWS CLI, you explicitly add the writer DB instance using the `create-db-instance` command. Include the following parameter:

- `--db-instance-class db.serverless`

The following example shows the creation of an Aurora Serverless v2 writer DB instance.

```
aws rds create-db-instance \
--db-cluster-identifier my-serverless-v2-cluster \
--db-instance-identifier my-serverless-v2-instance \
--db-instance-class db.serverless \
--engine aurora-mysql
```

## Adding an Aurora Serverless v2 reader

To add an Aurora Serverless v2 reader DB instance to your cluster, you follow the same general procedure as in [Adding Aurora Replicas to a DB cluster \(p. 270\)](#). Choose the **Serverless v2** instance class for the new DB instance.

If the reader DB instance is the first Aurora Serverless v2 DB instance in the cluster, you also choose the capacity range. The following image shows the controls that you use to specify the minimum and maximum Aurora capacity units (ACUs). This setting applies to this reader DB instance and to any other Aurora Serverless v2 DB instances that you add to the cluster. Each Aurora Serverless v2 DB instance can scale between the minimum and maximum ACU values.

### Instance configuration

The DB instance configuration options below are limited to those supported by the engine.

#### DB instance class [Info](#)

- Serverless v2**
- Memory optimized classes (includes r classes)**
- Burstable classes (includes t classes)**

#### Capacity range [Info](#)

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and networking.

##### Minimum ACUs

4.5	▼	(8 GiB)
-----	---	---------

0.5 to 128 in increments of 0.5

##### Maximum ACUs

16	(32 GiB)
----	----------

0.5 to 128 in increments of 0.5

If you already added any Aurora Serverless v2 DB instances to the cluster, adding another Aurora Serverless v2 reader DB instance shows you the current capacity range. The following image shows those read-only controls.

## Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected.

### DB instance class [Info](#)

- Serverless v2
- Memory optimized classes (includes r classes)
- Burstable classes (includes t classes)

### Capacity range [Info](#)

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and networking.

Minimum ACUs

2 ACUs (4 GiB)

Maximum ACUs

64 ACUs (128 GiB)

If you want to change the capacity range for the cluster, follow the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster \(p. 1510\)](#).

For clusters containing more than one reader DB instance, the failover priority of each Aurora Serverless v2 reader DB instance plays an important part in how that DB instance scales up and down. You can't specify the priority when you initially create the cluster. Keep this property in mind when you add a second reader or later DB instance to your cluster. For more information, see [Choosing the promotion tier for an Aurora Serverless v2 reader \(p. 1521\)](#).

For other ways that you can see the current capacity range for a cluster, see [Checking the capacity range for Aurora Serverless v2 \(p. 1513\)](#).

## Converting a provisioned writer or reader to Aurora Serverless v2

You can convert a provisioned DB instance to use Aurora Serverless v2. To do so, you follow the procedure in [Modify a DB instance in a DB cluster \(p. 249\)](#). The cluster must meet the requirements in [Requirements for Aurora Serverless v2 \(p. 1490\)](#). For example, Aurora Serverless v2 DB instances require that the cluster be running certain minimum engine versions.

Suppose that you are converting a running provisioned cluster to take advantage of Aurora Serverless v2. In that case, you can minimize downtime by converting a DB instance to Aurora Serverless v2 as the first step in the switchover process. For the full procedure, see [Switching from a provisioned cluster to Aurora Serverless v2 \(p. 1495\)](#).

If the DB instance that you convert is the first Aurora Serverless v2 DB instance in the cluster, you choose the capacity range for the cluster as part of the **Modify** operation. This capacity range applies to each Aurora Serverless v2 DB instance that you add to the cluster. The following image shows the page where you specify the minimum and maximum Aurora capacity units (ACUs).

## Instance configuration

The DB instance configuration options below are limited to those supported by the engine.

### DB instance class [Info](#)

- Serverless v2
- Memory optimized classes (includes r classes)
- Burstable classes (includes t classes)

### Capacity range [Info](#)

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and 1 GiB of networking.

Minimum ACUs

4.5  (8 GiB)

0.5 to 128 in increments of 0.5

Maximum ACUs

16 (32 GiB)

0.5 to 128 in increments of 0.5

For details about the significance of the capacity range, see [Aurora Serverless v2 capacity \(p. 1486\)](#).

If the cluster already contains one or more Aurora Serverless v2 DB instances, you see the existing capacity range during the **Modify** operation. The following image shows an example of that information panel.

## Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected.

### DB instance class [Info](#)

- Serverless v2
- Memory optimized classes (includes r classes)
- Burstable classes (includes t classes)

### Capacity range [Info](#)

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and networking.

Minimum ACUs

2 ACUs (4 GiB)

Maximum ACUs

64 ACUs (128 GiB)

If you want to change the capacity range for the cluster after you add more Aurora Serverless v2 DB instances, follow the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster \(p. 1510\)](#).

## Converting an Aurora Serverless v2 writer or reader to provisioned

You can convert an Aurora Serverless v2 DB instance to a provisioned DB instance. To do so, you follow the procedure in [Modify a DB instance in a DB cluster \(p. 249\)](#). Choose a DB instance class other than **Serverless**.

You might convert an Aurora Serverless v2 DB instance to provisioned if it needs a larger capacity than is available with the maximum Aurora capacity units (ACUs) of an Aurora Serverless v2 DB instance. For example, the largest db.r5 and db.r6g DB instance classes have a larger memory capacity than an Aurora Serverless v2 DB instance can scale to.

### Tip

Some of the older DB instance classes such as db.r3 and db.t2 aren't available for the Aurora versions that you use with Aurora Serverless v2. To see which DB instance classes you can use when converting an Aurora Serverless v2 DB instance to a provisioned one, see [Supported DB engines for DB instance classes \(p. 57\)](#).

If you are converting the writer DB instance of your cluster from Aurora Serverless v2 to provisioned, you can follow the procedure in [Switching from a provisioned cluster to Aurora Serverless v2 \(p. 1495\)](#) but in reverse. Switch one of the reader DB instances in the cluster from Aurora Serverless v2 to provisioned. Then perform a failover to make that provisioned DB instance into the writer.

Any capacity range that you previously specified for the cluster remains in place, even if all Aurora Serverless v2 DB instances are removed from the cluster. If you want to change the capacity range, you can modify the cluster, as explained in [Setting the Aurora Serverless v2 capacity range for a cluster \(p. 1510\)](#).

## Choosing the promotion tier for an Aurora Serverless v2 reader

For clusters containing multiple Aurora Serverless v2 DB instances or a mixture of provisioned and Aurora Serverless v2 DB instances, pay attention to the promotion tier setting for each Aurora Serverless v2 DB instance. This setting controls more behavior for Aurora Serverless v2 DB instances than for provisioned DB instances.

In the AWS Management Console, you specify this setting using the **Failover priority** choice under **Additional configuration** for the **Create database**, **Modify instance**, and **Add reader** pages. You see this property for existing DB instances in the optional **Priority tier** column on the **Databases** page. You can also see this property on the details page for a DB cluster or DB instance.

For provisioned DB instances, the choice of tier 0–15 determines only the order in which Aurora chooses which reader DB instance to promote to the writer during a failover operation. For Aurora Serverless v2 reader DB instances, the tier number also determines whether the DB instance scales up to match the capacity of the writer DB instance or scales independently based on its own workload. Aurora Serverless v2 reader DB instances in tier 0 or 1 are kept at a minimum capacity at least as high as the writer DB instance. That way, they are ready to take over from the writer DB instance in case of a failover. If the writer DB instance is a provisioned DB instance, Aurora estimates the equivalent Aurora Serverless v2 capacity. It uses that estimate as the minimum capacity for the Aurora Serverless v2 reader DB instance.

Aurora Serverless v2 reader DB instances in tiers 2–15 don't have the same constraint on their minimum capacity. When they are idle, they can scale down to the minimum Aurora capacity unit (ACU) value specified in the cluster's capacity range.

The following Linux AWS CLI example shows how to examine the promotion tiers of all the DB instances in your cluster. The final field includes a value of `True` for the writer DB instance and `False` for all the reader DB instances.

```
$ aws rds describe-db-clusters --db-cluster-identifier promotion-tier-demo \
--query 'DBClusters[*].DBClusterMembers[*]' \
[PromotionTier,DBInstanceIdentifier,IsClusterWriter]' \
--output text

1  instance-192  True
1  tier-01-4840  False
10 tier-10-7425  False
15 tier-15-6694  False
```

The following Linux AWS CLI example shows how to change the promotion tier of a specific DB instance in your cluster. The commands first modify the DB instance with a new promotion tier. Then they wait for the DB instance to become available again and confirm the new promotion tier for the DB instance.

```
$ aws rds modify-db-instance --db-instance-identifier instance-192 --promotion-tier 0
$ aws rds wait db-instance-available --db-instance-identifier instance-192
$ aws rds describe-db-instances --db-instance-identifier instance-192 \
--query '*[].[PromotionTier]' --output text
0
```

For more guidance about specifying promotion tiers for different use cases, see [Aurora Serverless v2 scaling \(p. 1487\)](#).

## Using TLS/SSL with Aurora Serverless v2

Aurora Serverless v2 can use the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt communications between clients and your Aurora Serverless v2 DB instances. It supports TLS/

SSL versions 1.0, 1.1, and 1.2. For general information about using TLS/SSL with Aurora, see [Using SSL/TLS with Aurora MySQL DB clusters \(p. 683\)](#).

To learn more about connecting to Aurora MySQL database with the MySQL client, see [Connecting to a DB instance running the MySQL database engine](#).

Aurora Serverless v2 supports all TLS/SSL modes available to the MySQL client (`mysql`) and PostgreSQL client (`psql`), including those listed in the following table.

Description of TLS/SSL mode	<code>mysql</code>	<code>psql</code>
Connect without using TLS/SSL.	DISABLED	disable
Try the connection using TLS/SSL first, but fall back to non-SSL if necessary.	PREFERRED	prefer (default)
Enforce using TLS/SSL.	REQUIRED	require
Enforce TLS/SSL and verify the certificate authority (CA).	VERIFY_CA	verify-ca
Enforce TLS/SSL, verify the CA, and verify the CA hostname.	VERIFY_IDENTITY	verify-full

Aurora Serverless v2 uses wildcard certificates. If you specify the "verify CA" or the "verify CA and CA hostname" option when using TLS/SSL, first download the [Amazon root CA 1 trust store](#) from Amazon Trust Services. After doing so, you can identify this PEM-formatted file in your client command. To do so using the PostgreSQL client, do the following.

For Linux, macOS, or Unix:

```
psql 'host=endpoint user=user sslmode=require sslrootcert=amazon-root-CA-1.pem dbname=db-name'
```

To learn more about working with the Aurora PostgreSQL database using the Postgres client, see [Connecting to a DB instance running the PostgreSQL database engine](#).

For more information about connecting to Aurora DB clusters in general, see [Connecting to an Amazon Aurora DB cluster \(p. 207\)](#).

## Supported cipher suites for connections to Aurora Serverless v2 DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client TLS/SSL connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of ciphers that aren't secure or that are no longer used.

Aurora Serverless v2 DB clusters that are based on Aurora MySQL support the same cipher suites as Aurora MySQL provisioned DB clusters. For information about these cipher suites, see [Configuring cipher suites for connections to Aurora MySQL DB clusters \(p. 685\)](#).

Aurora Serverless v2 DB clusters that are based on Aurora PostgreSQL support the same cipher suites as Aurora PostgreSQL provisioned DB clusters. For information about these cipher suites, see [Configuring cipher suites for connections to Aurora PostgreSQL DB clusters \(p. 1031\)](#).

## Viewing Aurora Serverless v2 writers and readers

You can view the details of Aurora Serverless v2 DB instances in the same way that you do for provisioned DB instances. To do so, follow the general procedure from [Viewing an Amazon Aurora DB cluster \(p. 433\)](#). A cluster might contain all Aurora Serverless v2 DB instances, all provisioned DB instances, or some of each.

After you create one or more Aurora Serverless v2 DB instances, you can view which DB instances are type **Serverless** and which are type **Instance**. You can also view the minimum and maximum Aurora capacity units (ACUs) that the Aurora Serverless v2 DB instance can use. Each ACU is a combination of processing (CPU) and memory (RAM) capacity. This capacity range applies to each Aurora Serverless v2 DB instance in the cluster. For the procedure to check the capacity range of a cluster or any Aurora Serverless v2 DB instance in the cluster, see [Checking the capacity range for Aurora Serverless v2 \(p. 1513\)](#).

In the AWS Management Console, Aurora Serverless v2 DB instances are marked under the **Size** column in the **Databases** page. Provisioned DB instances show the name of a DB instance class such as r6g.xlarge. The Aurora Serverless DB instances show **Serverless** for the DB instance class, along with the DB instance's minimum and maximum capacity. For example, you might see **Serverless v2 (4–64 ACUs)** or **Serverless v2 (1–40 ACUs)**.

You can find the same information on the **Configuration** tab for each Aurora Serverless v2 DB instance in the console. For example, you might see an **Instance type** section such as the following. Here, the **Instance type** value is **Serverless v2**, the **Minimum capacity** value is **2 ACUs (4 GiB)**, and the **Maximum capacity** value is **64 ACUs (128 GiB)**.

---

### Instance configuration

Instance type

Serverless v2

Minimum capacity

2 ACUs (4 GiB)

Maximum capacity

64 ACUs (128 GiB)

You can monitor the capacity of each Aurora Serverless v2 DB instance over time. That way, you can check the minimum, maximum, and average ACUs consumed by each DB instance. You can also check how close the DB instance came to its minimum or maximum capacity. To see such details in the AWS Management Console, examine the graphs of Amazon CloudWatch metrics on the **Monitoring** tab for the DB instance. For information about the metrics to watch and how to interpret them, see [Important Amazon CloudWatch metrics for Aurora Serverless v2 \(p. 1539\)](#).

## Logging for Aurora Serverless v2

To turn on database logging, you specify the logs to enable using configuration parameters in your custom parameter group.

For Aurora MySQL, you can enable the following logs.

Aurora MySQL	Description
<code>general_log</code>	Creates the general log. Set to 1 to turn on. Default is off (0).
<code>log_queries_not_using_indexes</code>	Logs any queries to the slow query log that don't use an index. Default is off (0). Set to 1 to turn on this log.
<code>long_query_time</code>	Prevents fast-running queries from being logged in the slow query log. Can be set to a float between 0 and 31536000. Default is 0 (not active).
<code>server_audit_events</code>	The list of events to capture in the logs. Supported values are CONNECT, QUERY, QUERY_DCL, QUERY_DDL, QUERY_DML, and TABLE.
<code>server_audit_logging</code>	Set to 1 to turn on server audit logging. If you turn this on, you can specify the audit events to send to CloudWatch by listing them in the <code>server_audit_events</code> parameter.
<code>slow_query_log</code>	Creates a slow query log. Set to 1 to turn on the slow query log. Default is off (0).

For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster \(p. 823\)](#).

For Aurora PostgreSQL, you can enable the following logs on your Aurora Serverless v2 DB instances.

Aurora PostgreSQL	Description
<code>log_connections</code>	Logs each successful connection.
<code>log_disconnections</code>	Logs end of a session including duration.
<code>log_lock_waits</code>	Default is 0 (off). Set to 1 to log lock waits.
<code>log_min_duration_statement</code>	The minimum duration (in milliseconds) for a statement to run before it's logged.
<code>log_min_messages</code>	Sets the message levels that are logged. Supported values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic. To log performance data to the <code>postgres</code> log, set the value to debug1.
<code>log_temp_files</code>	Logs the use of temporary files that are above the specified kilobytes (kB).
<code>log_statement</code>	Controls the specific SQL statements that get logged. Supported values are none, ddl, mod, and all. Default is none.

## Topics

- [Logging with Amazon CloudWatch \(p. 1525\)](#)
- [Viewing Aurora Serverless v2 logs in Amazon CloudWatch \(p. 1525\)](#)
- [Monitoring capacity with Amazon CloudWatch \(p. 1526\)](#)

## Logging with Amazon CloudWatch

After you use the procedure in [Logging for Aurora Serverless v2 \(p. 1523\)](#) to choose which database logs to turn on, you can choose which logs to upload ("publish") to Amazon CloudWatch.

You can use Amazon CloudWatch to analyze log data, create alarms, and view metrics. By default, error logs for Aurora Serverless v2 are enabled and automatically uploaded to CloudWatch. You can also upload other logs from Aurora Serverless v2 DB instances to CloudWatch.

Then you choose which of those logs to upload to CloudWatch, by using the **Log exports** settings in the AWS Management Console or the `--enable-cloudwatch-logs-exports` option in the AWS CLI.

You can choose which of your Aurora Serverless v2 logs to upload to CloudWatch.

As with any type of Aurora DB cluster, you can't modify the default DB cluster parameter group. Instead, create your own DB cluster parameter group based on a default parameter for your DB cluster and engine type. For Aurora Serverless v2 and Aurora Serverless, you use a DB cluster parameter group only.

We recommend that you create your custom DB cluster parameter group before creating your Aurora Serverless v2 DB cluster, so that it's available to choose when you create a database on the console.

For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster \(p. 823\)](#).

After you apply your modified DB cluster parameter group to your Aurora Serverless v2 DB cluster, you can view the logs in CloudWatch.

### To view Aurora Serverless v2 logs

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Choose **Log groups**.
3. Choose your Aurora Serverless v2 DB cluster log from the list. For error logs, the naming pattern is as follows.

```
/aws/rds/cluster/cluster_name/log_type
```

For more information on viewing details on your logs, see [Monitoring log events in Amazon CloudWatch \(p. 927\)](#).

## Viewing Aurora Serverless v2 logs in Amazon CloudWatch

After you use the procedure in [Logging for Aurora Serverless v2 \(p. 1523\)](#) to choose which database logs to turn on, you can view the contents of the logs.

For more information on using CloudWatch with Aurora MySQL and Aurora PostgreSQL logs, see [Monitoring log events in Amazon CloudWatch \(p. 927\)](#) and [Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs \(p. 1265\)](#).

### To view logs for your Aurora Serverless v2 DB cluster

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Choose your AWS Region.

3. Choose **Log groups**.
4. Choose your Aurora Serverless v2 DB cluster log from the list. For error logs, the naming pattern is as follows.

```
/aws/rds/cluster/cluster-name/error
```

## Monitoring capacity with Amazon CloudWatch

With Aurora Serverless v2, you can use CloudWatch to monitor the capacity and utilization of all the Aurora Serverless v2 DB instances in your cluster. You can view instance-level metrics to check the capacity of each Aurora Serverless v2 DB instance as it scales up and down. You can also compare the capacity-related metrics to other metrics to see how changes in workloads affect resource consumption. For example, you can compare `ServerlessDatabaseCapacity` to `DatabaseUsedMemory`, `DatabaseConnections`, and `DMLThroughput` to assess how your DB cluster is responding during operations. For details about the capacity-related metrics that apply to Aurora Serverless v2, see [Important Amazon CloudWatch metrics for Aurora Serverless v2 \(p. 1539\)](#).

### To monitor your Aurora Serverless v2 DB cluster's capacity

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Choose **Metrics**. All available metrics appear as cards in the console, grouped by service name.
3. Choose **RDS**.
4. (Optional) Use the **Search** box to find the metrics that are especially important for Aurora Serverless v2: `ServerlessDatabaseCapacity`, `ACUUtilization`, `CPUUtilization`, and `FreeableMemory`.

We recommend that you set up a CloudWatch dashboard to monitor your Aurora Serverless v2 DB cluster capacity using the capacity-related metrics. To learn how, see [Building dashboards with CloudWatch](#).

To learn more about using Amazon CloudWatch with Amazon Aurora, see [Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs \(p. 924\)](#).

## Performance and scaling for Aurora Serverless v2

The following procedures and examples show how you can set the capacity range for Aurora Serverless v2 clusters and their associated DB instances. You can also use procedures following to monitor how busy your DB instances are. Then you can use your findings to determine if you need to adjust the capacity range upward or downward.

Before you use these procedures, make sure that you are familiar with how Aurora Serverless v2 scaling works. The scaling mechanism is different than in Aurora Serverless v1. For details, see [Aurora Serverless v2 scaling \(p. 1487\)](#).

## Choosing the Aurora Serverless v2 capacity range for an Aurora cluster

With Aurora Serverless v2 DB instances, you set the capacity range that applies to all the DB instances in your DB cluster at the same time that you add the first Aurora Serverless v2 DB instance to the DB cluster. For the procedure to do so, see [Setting the Aurora Serverless v2 capacity range for a cluster \(p. 1510\)](#).

You can also change the capacity range for an existing cluster. The following sections discuss in more detail how to choose appropriate minimum and maximum values and what happens when you make a change to the capacity range. For example, changing the capacity range can modify the default values of some configuration parameters. Applying all the parameter changes can require rebooting each Aurora Serverless v2 DB instance.

### Topics

- [Choosing the minimum Aurora Serverless v2 capacity setting for a cluster \(p. 1527\)](#)
- [Choosing the maximum Aurora Serverless v2 capacity setting for a cluster \(p. 1528\)](#)

- [Example: Change the Aurora Serverless v2 capacity range of an Aurora PostgreSQL cluster \(p. 1532\)](#)

## Choosing the minimum Aurora Serverless v2 capacity setting for a cluster

It's tempting to always choose 0.5 for the minimum Aurora Serverless v2 capacity setting. That value allows the DB instance to scale down the most when it's completely idle. However, depending on how you use that cluster and the other settings that you configure, a different value might be the most effective. Consider the following factors when choosing the minimum capacity setting:

- The scaling rate for an Aurora Serverless v2 DB instance depends on its current capacity. The higher the current capacity, the faster it can scale up. If you need the DB instance to quickly scale up to a very high capacity, consider setting the minimum capacity to a value where the scaling rate meets your requirement.
- If you typically modify the DB instance class of your DB instances in anticipation of especially high or low workload, you can use that experience to make a rough estimate of the equivalent Aurora Serverless v2 capacity range. To determine the memory size to use in times of low traffic, consult [Hardware specifications for DB instance classes for Aurora \(p. 64\)](#).

For example, suppose that you use the db.r6g.xlarge DB instance class when your cluster has a low workload. That DB instance class has 32 GiB of memory. Thus, you can specify a minimum Aurora capacity unit (ACU) setting of 16 to set up an Aurora Serverless v2 DB instance that can scale down

to approximately that same capacity. That's because each ACU corresponds to approximately 2 GiB of memory. You might specify a somewhat lower value to let the DB instance scale down further in case your db.r6g.xlarge DB instance was sometimes underutilized.

- If your application works most efficiently when the DB instances have a certain amount of data in the buffer cache, consider specifying a minimum ACU setting where the memory is large enough to hold the frequently accessed data. Otherwise, some data is evicted from the buffer cache when the Aurora Serverless v2 DB instances scale down to a lower memory size. Then when the DB instances scale back up, the information is read back into the buffer cache over time. If the amount of I/O to bring the data back into the buffer cache is substantial, it might be more effective to choose a higher minimum ACU value.
- If your Aurora Serverless v2 DB instances run most of the time at a particular capacity, consider specifying a minimum capacity setting that's lower than that baseline, but not too much lower. Aurora Serverless v2 DB instances can most effectively estimate how much and how fast to scale up when the current capacity isn't drastically lower than the required capacity.
- If your provisioned workload has memory requirements that are too high for small DB instance classes such as T3 or T4g, choose a minimum ACU setting that provides memory comparable to an R5 or R6g DB instance.

In particular, we recommend the following minimum capacity for use with the specified features (these recommendations are subject to change):

- **Performance Insights** – 2 ACUs.
- In some cases, your cluster might contain Aurora Serverless v2 reader DB instances that scale independently from the writer. If so, choose a minimum capacity setting that's high enough that when the writer DB instance is busy with a write-intensive workload, the reader DB instances can apply the changes from the writer without falling behind. If you observe replica lag in readers that are in promotion tiers 2–15, consider increasing the minimum capacity setting for your cluster. For details on choosing whether reader DB instances scale along with the writer or independently, see [Choosing the promotion tier for an Aurora Serverless v2 reader \(p. 1521\)](#).
- If you have a mixed-configuration cluster with a provisioned writer and Aurora Serverless v2 readers, the readers can't scale along with the writer. In that case, setting a low minimum capacity can result in excessive replication lag. That's because the readers might not have enough capacity to apply changes from the writer when the database is busy. When your cluster uses a provisioned writer, set the minimum capacity to a value that represents a comparable amount of memory and CPU to the writer.
- For Aurora PostgreSQL, when you specify a minimum Aurora Serverless v2 capacity of 0.5, the `max_connections` setting is permanently capped at 2000. If you intend to use the Aurora PostgreSQL cluster for a high-connection workload, consider using a minimum ACU setting of 1 or higher. For details about how Aurora Serverless v2 handles the `max_connections` configuration parameter, see [Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity \(p. 1537\)](#).
- The time it takes for an Aurora Serverless v2 DB instance to scale from its minimum capacity to its maximum capacity depends on the difference between its minimum and maximum ACU values. When the current capacity of the DB instance is large, Aurora Serverless v2 scales up in larger increments than when the DB instance starts from a small capacity. Thus, if you specify a relatively large maximum capacity and the DB instance spends most of its time near that capacity, consider increasing the minimum ACU setting. That way, an idle DB instance can scale back up to maximum capacity more quickly.

## Choosing the maximum Aurora Serverless v2 capacity setting for a cluster

It's tempting to always choose some high value for the maximum Aurora Serverless v2 capacity setting. A large maximum capacity allows the DB instance to scale up the most when it's running an intensive

workload. A low value avoids the possibility of unexpected charges. Depending on how you use that cluster and the other settings that you configure, the most effective value might be higher or lower than you originally thought. Consider the following factors when choosing the maximum capacity setting:

- The maximum capacity must be at least as high as the minimum capacity. You can set the minimum and maximum capacity to be identical. However, in that case the capacity never scales up or down. Thus, using identical values for minimum and maximum capacity isn't appropriate outside of testing situations.
- The maximum capacity must be higher than 0.5 ACUs. You can set the minimum and maximum capacity to be the same in most cases. However, you can't specify 0.5 for both the minimum and maximum. Use a value of 1 or higher for the maximum capacity.
- If you typically modify the DB instance class of your DB instances in anticipation of especially high or low workload, you can use that experience to estimate the equivalent Aurora Serverless v2 capacity range. To determine the memory size to use in times of high traffic, consult [Hardware specifications for DB instance classes for Aurora \(p. 64\)](#).

For example, suppose that you use the db.r6g.4xlarge DB instance class when your cluster has a high workload. That DB instance class has 128 GiB of memory. Thus, you can specify a maximum ACU setting of 64 to set up an Aurora Serverless v2 DB instance that can scale up to approximately that same capacity. That's because each ACU corresponds to approximately 2 GiB of memory. You might specify a somewhat higher value to let the DB instance scale up farther in case your db.r6g.4xlarge DB instance sometimes doesn't have enough capacity to handle the workload effectively.

- If you have a budgetary cap on your database usage, choose a value that stays within that cap even if all your Aurora Serverless v2 DB instances run at maximum capacity all the time. Remember that when you have  $n$  Aurora Serverless v2 DB instances in your cluster, the theoretical maximum Aurora Serverless v2 capacity that the cluster can consume at any moment is  $n$  times the maximum ACU setting for the cluster. (The actual amount consumed might be less, for example if some readers scale independently from the writer.)
- If you make use of Aurora Serverless v2 reader DB instances to offload some of the read-only workload from the writer DB instance, you might be able to choose a lower maximum capacity setting. You do this to reflect that each reader DB instance doesn't need to scale as high as if the cluster contains only a single DB instance.
- Suppose that you want to protect against excessive usage due to misconfigured database parameters or inefficient queries in your application. In that case, you might avoid accidental overuse by choosing a maximum capacity setting that's lower than the absolute highest that you could set.
- If spikes due to real user activity are rare but do happen, you can take those occasions into account when choosing the maximum capacity setting. If the priority is for the application to keep running with full performance and scalability, you can specify a maximum capacity setting that's higher than you observe in normal usage. If it's OK for the application to run with reduced throughput during very extreme spikes in activity, you can choose a slightly lower maximum capacity setting. Make sure that you choose a setting that still has enough memory and CPU resources to keep the application running.
- If you turn on settings in your cluster that increase the memory usage for each DB instance, take that memory into account when deciding on the maximum ACU value. Such settings include those for Performance Insights, Aurora MySQL parallel queries, Aurora MySQL performance schema, and Aurora MySQL binary log replication. Make sure that the maximum ACU value allows the Aurora Serverless v2 DB instances to scale up enough to handle the workload when those feature are being used. For information about troubleshooting problems caused by the combination of a low maximum ACU setting and Aurora features that impose memory overhead, see [Avoiding out-of-memory errors \(p. 1538\)](#).

## Example: Change the Aurora Serverless v2 capacity range of an Aurora MySQL cluster

The following AWS CLI example shows how to update the ACU range for Aurora Serverless v2 DB instances in an existing Aurora MySQL cluster. Initially, the ACU range for the cluster 8–32.

```
$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
--query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'

{
    "MinCapacity": 8.0,
    "MaxCapacity": 32.0
}
```

The following capacity-related settings apply to the DB instance at this point. The DB instance is idle and scaled down to 8 ACUs. To represent the size of the buffer pool in easily readable units, we divide it by 2 to the power of 30, yielding a measurement in gibibytes (GiB). That's because memory-related measurements for Aurora use units based on powers of 2, not powers of 10.

```
mysql> select @@max_connections;
+-----+
| @@max_connections |
+-----+
|          3000 |
+-----+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|      9294577664 |
+-----+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----+
| gibibytes |
+-----+
|     8.65625 |
+-----+
1 row in set (0.00 sec)
```

Next, we change the capacity range for the cluster. After the `modify-db-cluster` command finishes, the ACU range for the cluster is 12.5–80.

```
$ aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \
--serverless-v2-scaling-configuration MinCapacity=12.5,MaxCapacity=80

$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
--query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'

{
    "MinCapacity": 12.5,
    "MaxCapacity": 80.0
}
```

Changing the capacity range caused changes to the default values of some configuration parameters. Aurora can apply some of those new defaults immediately. However, some of the parameter changes take effect only after a reboot. The pending-reboot status indicates that a reboot is needed to apply some parameter changes.

**Tip**

You can reboot the DB instances yourself to apply these parameter changes. Or you can wait for Aurora to do the reboot and apply the parameter changes during your next scheduled maintenance window.

```
$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
--query '*[].[{DBClusterMembers:DBClusterMembers[*]}, \
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGroupStatus}][0]' \
{
    "DBClusterMembers": [
        {
            "DBInstanceIdentifier": "serverless-v2-instance-1",
            "DBClusterParameterGroupStatus": "pending-reboot"
        }
    ]
}
```

The following example shows how the `innodb_buffer_pool_size` parameter is already adjusted based on the current capacity of the DB instance. At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 12.5 ACUs. The `max_connections` parameter still reflects the value from the former capacity range. Resetting that value requires rebooting the DB instance.

```
mysql> select @@max_connections;
+-----+
| @@max_connections |
+-----+
|          3000 |
+-----+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|      15572402176 |
+-----+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----+
| gibibytes   |
+-----+
| 14.5029296875 |
+-----+
1 row in set (0.00 sec)
```

Now we reboot the DB instance and wait for it to become available again.

```
$ aws rds reboot-db-instance --db-instance-identifier serverless-v2-instance-1 \
{
    "DBInstanceIdentifier": "serverless-v2-instance-1",
    "DBInstanceState": "rebooting"
}
$ aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
```

Now that the DB instance is rebooted, the `pending-reboot` status is cleared. The value `in-sync` confirms that Aurora has applied all the pending parameter changes.

```
$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
```

```
--query '*[].[DBClusterMembers:DBClusterMembers[*].{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGroupStatus}[0]'.
{
    "DBClusterMembers": [
        {
            "DBInstanceIdentifier": "serverless-v2-instance-1",
            "DBClusterParameterGroupStatus": "in-sync"
        }
    ]
}
```

The following example checks the same parameters as before the reboot. The `innodb_buffer_pool_size` parameter has increased to its final size for an idle DB instance. The `max_connections` parameter has increased to reflect a value derived from the maximum ACU value. The formula that Aurora uses for `max_connections` causes an increase of 1,000 when the memory size doubles.

```
mysql> select @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
| 16139681792 |
+-----+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----+
| gibibytes |
+-----+
| 15.03125 |
+-----+
1 row in set (0.00 sec)

mysql> select @@max_connections;
+-----+
| @@max_connections |
+-----+
| 4000 |
+-----+
1 row in set (0.00 sec)
```

In the following example, we used the same procedure as before to set the capacity range at 0.5–128 ACUs. We rebooted the DB instance to apply any resulting changes to static parameters. Now the idle DB instance has a buffer cache size that's less than 1 GiB, so we measure it in mebibytes (MiB). The `max_connections` value of 5000 is derived from the memory size of the maximum capacity setting.

```
mysql> select @@innodb_buffer_pool_size / pow(2,20) as mebibytes, @@max_connections;
+-----+
| mebibytes | @@max_connections |
+-----+
| 672 | 5000 |
+-----+
1 row in set (0.00 sec)
```

## Example: Change the Aurora Serverless v2 capacity range of an Aurora PostgreSQL cluster

The following CLI example shows how to update the ACU range for Aurora Serverless v2 DB instances in an existing Aurora PostgreSQL cluster. Initially, the ACU range for the cluster is 8–32.

```
$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
--query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 8.0,
    "MaxCapacity": 32.0
}
```

The following capacity-related settings apply to the DB instance at this point. The DB instance is idle and scaled down to 8 ACUs.

```
postgres=> show shared_buffers;
shared_buffers
-----
1327104
(1 row)

postgres=> show max_connections;
max_connections
-----
2000
(1 row)
```

Next, we change the capacity range for the cluster. After the `modify-db-cluster` command finishes, the ACU range for the cluster is 12.5–80.

```
$ aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \
--serverless-v2-scaling-configuration MinCapacity=12.5,MaxCapacity=80

$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
--query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 12.5,
    "MaxCapacity": 80.0
}
```

Changing the capacity range causes changes to the default values of some configuration parameters. Aurora can apply some of those new defaults immediately. However, some of the parameter changes take effect only after a reboot. The `pending-reboot` status indicates that you need a reboot to apply some parameter changes.

**Tip**

You can reboot the DB instances yourself to apply these parameter changes. Or you can wait for Aurora to do the reboot and apply the parameter changes during your next scheduled maintenance window.

```
$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
--query '*[].[DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGroupStatus}
[0]]'
{
    "DBClusterMembers": [
        {
            "DBInstanceIdentifier": "serverless-v2-instance-1",
            "DBClusterParameterGroupStatus": "pending-reboot"
        }
    ]
}
```

The following example shows how the `shared_buffers` parameter is already adjusted based on the current capacity of the DB instance. At this point, the cluster is idle and the DB instance `serverless-`

v2-instance-1 is consuming 12.5 ACUs. The `max_connections` parameter still reflects the value from the former capacity range. Resetting that value requires rebooting the DB instance.

```
postgres=> show shared_buffers;
shared_buffers
-----
344064
(1 row)

postgres=> show max_connections;
max_connections
-----
1034
(1 row)

postgres=> select name as parameter_name, setting, unit,
  (((setting::BIGINT)*8)/1024)::BIGINT as "size_MiB",
  postgres->   (((setting::BIGINT)*8)/1024/1024)::BIGINT as "size_GiB",
  pg_size.pretty(((setting::BIGINT)*8)*1024)::BIGINT)
postgres-> from pg_settings where name in ('shared_buffers');
parameter_name | setting | unit | size_MiB | size_GiB | pg_size.pretty
-----+-----+-----+-----+-----+
shared_buffers | 32768 | 8kB | 256 | 0 | 256 MB
(1 row)
```

Now we reboot the DB instance and wait for it to become available again.

```
$ aws rds reboot-db-instance --db-instance-identifier serverless-v2-instance-1
{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "DBInstanceState": "rebooting"
}
$ aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
```

Now that the DB instance is rebooted, the pending-reboot status is cleared. The value `in-sync` confirms that Aurora has applied all the pending parameter changes.

```
$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
--query '*[].[DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGroupStatus}[0]'.
{
  "DBClusterMembers": [
    {
      "DBInstanceIdentifier": "serverless-v2-instance-1",
      "DBClusterParameterGroupStatus": "in-sync"
    }
  ]
}
```

The following example checks the same parameters as before the reboot. The `shared_buffers` parameter has increased to its final size for an idle DB instance. The `max_connections` parameter has increased to reflect a value derived from the maximum ACU value.

```
postgres=> show shared_buffers;
shared_buffers
-----
1425408
```

```
(1 row)

postgres=> show max_connections;
max_connections
-----
1034
(1 row)

postgres=> select name as parameter_name, setting, unit,
  pg_size.pretty(((setting::BIGINT)*8)*1024)::BIGINT)
postgres->   from pg_settings where name in ('shared_buffers');
  parameter_name | setting | unit | pg_size.pretty
-----+-----+-----+
  shared_buffers | 1425408 | 8kB  | 11 GB
(1 row)
```

In the following example, we used the same procedure as before to set the capacity range from 0.5 to 128 ACUs. We rebooted the DB instance to apply any resulting changes to static parameters. The `max_connections` value of 2000 isn't derived from the maximum ACU setting. When the minimum ACU setting is 0.5, PostgreSQL-compatible Aurora Serverless v2 DB instances use a default `max_connections` value of 2000 regardless of the maximum ACU value.

```
postgres=> show shared_buffers;
shared_buffers
-----
2228224
(1 row)

postgres=> show max_connections;
max_connections
-----
1034
(1 row)

postgres=> select name as parameter_name, setting, unit,
  pg_size.pretty(((setting::BIGINT)*8)*1024)::BIGINT) from pg_settings where name in
  ('shared_buffers');
  parameter_name | setting | unit | pg_size.pretty
-----+-----+-----+
  shared_buffers | 2228224 | 8kB  | 17 GB
(1 row)
```

## Working with parameter groups for Aurora Serverless v2

When you create your Aurora Serverless v2 DB cluster, you choose a specific Aurora DB engine and an associated DB cluster parameter group. If you aren't familiar with how Aurora uses parameter groups to apply configuration settings consistently across clusters, see [Working with parameter groups \(p. 215\)](#). All of those procedures for creating, modifying, applying, and other actions for parameter groups apply to Aurora Serverless v2.

The parameter group feature works generally the same between provisioned clusters and clusters containing Aurora Serverless v2 DB instances:

- The default parameter values for all DB instances in the cluster are defined by the cluster parameter group.
- You can override some parameters for specific DB instances by specifying a custom DB parameter group for those DB instances. You might do so during debugging or performance tuning for specific DB instances. For example, suppose that you have a cluster containing some Aurora Serverless v2

DB instances and some provisioned DB instances. In this case, you might specify some different parameters for the provisioned DB instances by using a custom DB parameter group.

- For Aurora Serverless v2, you can use all the parameters that have the value `provisioned` in the `SupportedEngineModes` attribute in the parameter group. In Aurora Serverless v1, you can only use the subset of parameters that have `serverless` in the `SupportedEngineModes` attribute.

### Topics

- [Default parameter values \(p. 1536\)](#)
- [Parameters that Aurora adjusts as Aurora Serverless v2 scales up and down \(p. 1537\)](#)
- [Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity \(p. 1537\)](#)

## Default parameter values

The crucial difference between provisioned DB instances and Aurora Serverless v2 DB instances is that Aurora overrides any custom parameter values for certain parameters that are related to DB instance capacity. The custom parameter values still apply to any provisioned DB instances in your cluster. For more details about how Aurora Serverless v2 DB instances interpret the parameters from Aurora parameter groups, see [Configuration parameters for Aurora clusters \(p. 1489\)](#). For the specific parameters that Aurora Serverless v2 overrides, see [Parameters that Aurora adjusts as Aurora Serverless v2 scales up and down \(p. 1537\)](#) and [Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity \(p. 1537\)](#).

You can get a list of default values for the default parameter groups for the various Aurora DB engines by using the `describe-db-cluster-parameters` CLI command and querying the AWS Region. The following are values that you can use for the `--db-parameter-group-family` and `-db-parameter-group-name` options for engine versions that are compatible with Aurora Serverless v2.

Database engine and version	Parameter group family	Default parameter group name
Aurora MySQL version 3	<code>aurora-mysql8.0</code>	<code>default.aurora-mysql8.0</code>
Aurora PostgreSQL version 13.x	<code>aurora-postgresql13</code>	<code>default.aurora-postgresql13</code>

The following example gets a list of parameters from the default DB cluster group for Aurora MySQL version 3 and Aurora PostgreSQL 13. Those are the Aurora MySQL and Aurora PostgreSQL versions that you use with Aurora Serverless v2.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameters \
--db-cluster-parameter-group-name default.aurora-mysql8.0 \
--query 'Parameters[*]' \
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |
[?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]` \
--output text

aws rds describe-db-cluster-parameters \
--db-cluster-parameter-group-name default.aurora-postgresql13 \
--query 'Parameters[*]' \
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |
[?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]` \
--output text
```

For Windows:

```
aws rds describe-db-cluster-parameters ^
--db-cluster-parameter-group-name default.aurora-mysql8.0 ^
--query 'Parameters[*].{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | 
[?contains(SupportedEngineModes, `provisioned` ) == `true`] | [*].[ParameterName]' ^
--output text

aws rds describe-db-cluster-parameters ^
--db-cluster-parameter-group-name default.aurora-postgresql13 ^
--query 'Parameters[*].{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | 
[?contains(SupportedEngineModes, `provisioned` ) == `true`] | [*].[ParameterName]' ^
--output text
```

## Parameters that Aurora adjusts as Aurora Serverless v2 scales up and down

During autoscaling, Aurora Serverless v2 needs to be able to change parameters for each DB instance to work best for the increased or decreased capacity. Thus, you can't override some parameters related to capacity. For some parameters that you can override, avoid hardcoding fixed values. The following considerations apply to these settings that are related to capacity.

For Aurora MySQL, Aurora Serverless v2 resizes some parameters dynamically during scaling. For the following parameters, Aurora Serverless v2 doesn't use any custom parameter values that you specify:

- `innodb_buffer_pool_size`
- `innodb_purge_threads`
- `table_definition_cache`
- `table_open_cache`

For Aurora PostgreSQL, Aurora Serverless v2 resizes the following parameters parameter dynamically during scaling. For the following parameters, Aurora Serverless v2 doesn't use any custom parameter values that you specify:

- `shared_buffers`

For all parameters other than those listed here and in [Parameters that Aurora adjusts as Aurora Serverless v2 scales up and down \(p. 1537\)](#), Aurora Serverless v2 DB instances work the same as provisioned DB instances. The default parameter value is inherited from the cluster parameter group. You can modify the default for the whole cluster by using a custom cluster parameter group. Or you can modify the default for certain DB instances by using a custom DB parameter group. Dynamic parameters are updated immediately. Changes to static parameters only take effect after you reboot the DB instance.

## Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity

For both Aurora MySQL and Aurora PostgreSQL, Aurora Serverless v2 DB instances hold the `max_connections` parameter constant so that connections aren't dropped when the DB instance scales down. The default value for this parameter is derived from a formula that refers to the memory size of the DB instance. For details about the formula and the default values for provisioned DB instance classes, see [Maximum connections to an Aurora MySQL DB instance \(p. 722\)](#) and [Maximum connections to an Aurora PostgreSQL DB instance \(p. 1144\)](#).

When Aurora Serverless v2 evaluates the formula, it uses the memory size based on the maximum Aurora capacity units (ACUs) for the DB instance, not the current ACU value. If you change the default

value, we recommend using a variation of the formula instead of specifying a constant value. That way, Aurora Serverless v2 can use a setting that's sized appropriately based on the maximum capacity.

When you specify a minimum capacity of 0.5 ACUs, PostgreSQL-compatible Aurora Serverless v2 DB instances set an upper limit of 2000 on the `max_connections` setting.

For the following parameters, Aurora PostgreSQL also uses default values that are derived from the memory size based on the maximum ACU setting, the same as with `max_connections`:

- `autovacuum_max_workers`
- `autovacuum_vacuum_cost_limit`
- `autovacuum_work_mem`
- `effective_cache_size`
- `maintenance_work_mem`

## Avoiding out-of-memory errors

If one of your Aurora Serverless v2 DB instances consistently reaches the limit of its maximum capacity, Aurora indicates this condition by setting the DB instance to a status of `incompatible-parameters`. While the DB instance has the `incompatible-parameters` status, some operations are blocked. For example, you can't upgrade the engine version.

Typically, your DB instance goes into this status when it restarts frequently due to out-of-memory errors. Aurora records an event when this type of restart happens. You can view the event by following the procedure in [Viewing Amazon RDS events \(p. 569\)](#). Unusually high memory usage can happen because of overhead from turning on settings such as Performance Insights and IAM authentication. It can also come from a heavy workload on your DB instance or from managing the metadata associated with a large number of schema objects.

If the memory pressure becomes lower so that the DB instance doesn't reach its maximum capacity very often, Aurora automatically changes the DB instance status back to `available`.

To recover from this condition, you can take some or all of the following actions:

- Increase the lower limit on capacity for Aurora Serverless v2 DB instances by changing the minimum Aurora capacity unit (ACU) value for the cluster. Doing so avoids issues where an idle database scales down to a capacity with less memory than is needed for the features that are turned on in your cluster. After changing the ACU settings for the cluster, reboot the Aurora Serverless v2 DB instance. Doing so evaluates whether Aurora can reset the status back to `available`.
- Increase the upper limit on capacity for Aurora Serverless v2 DB instances by changing the maximum ACU value for the cluster. Doing so avoids issues where a busy database can't scale up to a capacity with enough memory for the features that are turned on in your cluster and the database workload. After changing the ACU settings for the cluster, reboot the Aurora Serverless v2 DB instance. Doing so evaluates whether Aurora can reset the status back to `available`.
- Turn off configuration settings that require memory overhead. For example, suppose that you have features such as AWS Identity and Access Management (IAM), Performance Insights, or Aurora MySQL binary log replication turned on but don't use them. If so, you can turn them off. Or you can adjust the minimum and maximum capacity values for the cluster higher to account for the memory used by those features. For guidelines about choosing minimum and maximum capacity settings, see [Choosing the Aurora Serverless v2 capacity range for an Aurora cluster \(p. 1527\)](#).
- Reduce the workload on the DB instance. For example, you can add reader DB instances to the cluster to spread the load from read-only queries across more DB instances.
- Tune the SQL code used by your application to use fewer resources. For example, you can examine your query plans, check the slow query log, or adjust the indexes on your tables. You can also perform other traditional kinds of SQL tuning.

## Important Amazon CloudWatch metrics for Aurora Serverless v2

To get started with Amazon CloudWatch for your Aurora Serverless v2 DB instance, see [Viewing Aurora Serverless v2 logs in Amazon CloudWatch \(p. 1525\)](#). To learn more about how to monitor Aurora DB clusters through CloudWatch, see [Monitoring log events in Amazon CloudWatch \(p. 927\)](#).

You can view your Aurora Serverless v2 DB instances in CloudWatch to monitor the capacity consumed by each DB instance with the `ServerlessDatabaseCapacity` metric. You can also monitor all of the standard Aurora CloudWatch metrics, such as `DatabaseConnections` and `Queries`. For the full list of CloudWatch metrics that you can monitor for Aurora, see [Amazon CloudWatch metrics for Amazon Aurora \(p. 525\)](#). The metrics are divided into cluster-level and instance-level metrics, in [Cluster-level metrics for Amazon Aurora \(p. 525\)](#) and [Instance-level metrics for Amazon Aurora \(p. 531\)](#).

The following CloudWatch instance-level metrics are important to monitor for you to understand how your Aurora Serverless v2 DB instances are scaling up and down. All of these metrics are calculated every second. That way, you can monitor the current status of your Aurora Serverless v2 DB instances. You can set alarms to notify you if any Aurora Serverless v2 DB instance approaches a threshold for metrics related to capacity. You can determine if the minimum and maximum capacity settings are appropriate, or if you need to adjust them. You can determine where to focus your efforts for optimizing the efficiency of your database.

- `ServerlessDatabaseCapacity`. As an instance-level metric, it reports the number of ACUs represented by the current DB instance capacity. As a cluster-level metric, it represents the average of the `ServerlessDatabaseCapacity` values of all the Aurora Serverless v2 DB instances in the cluster. This metric is only a cluster-level metric in Aurora Serverless v1. In Aurora Serverless v2, it's available at the DB instance level and at the cluster level.
- `ACUUtilization`. This metric is new in Aurora Serverless v2. This value is represented as a percentage. It's calculated as the value of the `ServerlessDatabaseCapacity` metric divided by the maximum ACU value of the DB cluster. Consider the following guidelines to interpret this metric and take action:
  - If this metric approaches a value of 100 . 0, the DB instance has scaled up as high as it can. Consider increasing the maximum ACU setting for the cluster. That way, both writer and reader DB instances can scale to a higher capacity.
  - Suppose that a read-only workload causes a reader DB instance to approach an `ACUUtilization` of 100 . 0, while the writer DB instance isn't close to its maximum capacity. In that case, consider adding additional reader DB instances to the cluster. That way, you can spread the read-only part of the workload spread across more DB instances, reducing the load on each reader DB instance.
  - Suppose that you are running a production application, where performance and scalability are the primary considerations. In that case, you can set the maximum ACU value for the cluster to a high number. Your goal is for the `ACUUtilization` metric to always be below 100 . 0. With a high maximum ACU value, you can be confident that there's enough room in case there are unexpected spikes in database activity. You are only charged for the database capacity that's actually consumed.
- `CPUUtilization`. This metric is interpreted differently in Aurora Serverless v2 than in provisioned DB instances. For Aurora Serverless v2, this value is a percentage that's calculated as the amount of CPU currently being used divided by the CPU capacity that's available under the maximum ACU value of the DB cluster. Aurora monitors this value automatically and scales up your Aurora Serverless v2 DB instance when the DB instance consistently uses a high proportion of its CPU capacity.

If this metric approaches a value of 100 . 0, the DB instance has reached its maximum CPU capacity. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of 100 . 0 on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, you can spread the read-only part of the workload spread across more DB instances, reducing the load on each reader DB instance.

- **FreeableMemory.** This value represents the amount of unused memory that is available when the Aurora Serverless v2 DB instance is scaled to its maximum capacity. For every ACU that the current capacity is below the maximum capacity, this value increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB instance is scaled up as high as it can.

If this metric approaches a value of 0, the DB instance has scaled up as much as it can and is nearing the limit of its available memory. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of 0 on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, the read-only part of the workload can be spread across more DB instances, reducing the memory usage on each reader DB instance.

- **TempStorageIops.** The number of IOPS done on local storage attached to the DB instance. It includes the IOPS for both reads and writes. This metric represents a count and is measured once per second. This is a new metric for Aurora Serverless v2. For details, see [Instance-level metrics for Amazon Aurora \(p. 531\)](#).
- **TempStorageThroughput.** The amount of data transferred to and from local storage associated with the DB instance. This metric represents bytes and is measured once per second. This is a new metric for Aurora Serverless v2. For details, see [Instance-level metrics for Amazon Aurora \(p. 531\)](#).

Typically, most scaling up for Aurora Serverless v2 DB instances is caused by memory usage and CPU activity. The **TempStorageIops** and **TempStorageThroughput** metrics can help you to diagnose the rare cases where network activity for transfers between your DB instance and local storage devices is responsible for unexpected capacity increases. To monitor other network activity, you can use these existing metrics:

- **NetworkReceiveThroughput**
- **NetworkThroughput**
- **NetworkTransmitThroughput**
- **StorageNetworkReceiveThroughput**
- **StorageNetworkThroughput**
- **StorageNetworkTransmitThroughput**

You can have Aurora publish some or all database logs to CloudWatch. You select the logs to publish by turning on the [configuration parameters such as general\\_log and slow\\_query\\_log in the DB cluster parameter group \(p. 1535\)](#) associated with the cluster that contains your Aurora Serverless v2 DB instances. When you turn off a log configuration parameter, publishing that log to CloudWatch stops. You can also delete the logs in CloudWatch if they are no longer needed.

## How Aurora Serverless v2 metrics apply to your AWS bill

The Aurora Serverless v2 charges on your AWS bill are calculated based on the same **ServerlessDatabaseCapacity** metric that you can monitor. The billing mechanism can differ from the computed CloudWatch average for this metric in cases where you use Aurora Serverless v2 capacity for only part of an hour. It can also differ if system issues make the CloudWatch metric unavailable for brief periods. Thus, you might see a slightly different value of ACU-hours on your bill than if you compute the number yourself from the **ServerlessDatabaseCapacity** average value.

## Examples of CloudWatch commands for Aurora Serverless v2 metrics

The following AWS CLI examples demonstrate how you can monitor the most important CloudWatch metrics related to Aurora Serverless v2. In each case, replace the `Value=` string for the `--dimensions` parameter with the identifier of your own Aurora Serverless v2 DB instance.

The following Linux example displays the minimum, maximum, and average capacity values for a DB instance, measured every 10 minutes over one hour. The `Linux date` command specifies the start and end times relative to the current date and time. The `sort_by` function in the `--query` parameter sorts the results chronologically based on the `Timestamp` field.

```
aws cloudwatch get-metric-statistics --metric-name "ServerlessDatabaseCapacity" \
--start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \
--namespace "AWS/RDS" --statistics Minimum Maximum Average \
--dimensions Name=DBInstanceIdentifier,Value=my_instance \
--query 'sort_by(Datapoints[*].{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' \
--output table
```

The following Linux examples demonstrate monitoring the capacity of each DB instance in a cluster. They measure the minimum, maximum, and average capacity utilization of each DB instance. The measurements are taken once each hour over a three-hour period. These examples use the `ACUUtilization` metric representing a percentage of the upper limit on ACUs, instead of `ServerlessDatabaseCapacity` representing a fixed number of ACUs. That way, you don't need to know the actual numbers for the minimum and maximum ACU values in the capacity range. You can see percentages ranging from 0 to 100.

```
aws cloudwatch get-metric-statistics --metric-name "ACUUtilization" \
--start-time "$(date -d '3 hours ago')" --end-time "$(date -d 'now')" --period 3600 \
--namespace "AWS/RDS" --statistics Minimum Maximum Average \
--dimensions Name=DBInstanceIdentifier,Value=my_writer_instance \
--query 'sort_by(Datapoints[*].{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' \
--output table

aws cloudwatch get-metric-statistics --metric-name "ACUUtilization" \
--start-time "$(date -d '3 hours ago')" --end-time "$(date -d 'now')" --period 3600 \
--namespace "AWS/RDS" --statistics Minimum Maximum Average \
--dimensions Name=DBInstanceIdentifier,Value=my_reader_instance \
--query 'sort_by(Datapoints[*].{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' \
--output table
```

The following Linux example does similar measurements as the previous ones. In this case, the measurements are for the `CPUUtilization` metric. The measurements are taken every 10 minutes over a 1-hour period. The numbers represent the percentage of available CPU used, based on the CPU resources available to the maximum capacity setting for the DB instance.

```
aws cloudwatch get-metric-statistics --metric-name "CPUUtilization" \
--start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \
--namespace "AWS/RDS" --statistics Minimum Maximum Average \
--dimensions Name=DBInstanceIdentifier,Value=my_instance \
--query 'sort_by(Datapoints[*].{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' \
--output table
```

The following Linux example does similar measurements as the previous ones. In this case, the measurements are for the `FreeableMemory` metric. The measurements are taken every 10 minutes over a 1-hour period.

```
aws cloudwatch get-metric-statistics --metric-name "FreeableMemory" \
--start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \
--namespace "AWS/RDS" --statistics Minimum Maximum Average \
--dimensions Name=DBInstanceIdentifier,Value=my_instance \
--query 'sort_by(Datapoints[*].{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' \
--output table
```

## Monitoring Aurora Serverless v2 performance with Performance Insights

You can use Performance Insights to monitor the performance of Aurora Serverless v2 DB instances. For Performance Insights procedures, see [Monitoring DB load with Performance Insights on Amazon Aurora \(p. 461\)](#).

The following new Performance Insights counters apply to Aurora Serverless v2 DB instances:

- `os.general.serverlessDatabaseCapacity` – The current capacity of the DB instance in ACUs. The value corresponds to the `ServerlessDatabaseCapacity` CloudWatch metric for the DB instance.
- `os.general.acuUtilization` – The percentage of current capacity out of the maximum configured capacity. The value corresponds to the `ACUUtilization` CloudWatch metric for the DB instance.
- `os.general.maxConfiguredAcu` – The maximum capacity that you configured for this Aurora Serverless v2 DB instance. It's measured in ACUs.
- `os.general.minConfiguredAcu` – The minimum capacity that you configured for this Aurora Serverless v2 DB instance. It's measured in ACUs

For the full list of Performance Insights counters, see [Performance Insights counter metrics \(p. 546\)](#).

When vCPU values are shown for an Aurora Serverless v2 DB instance in Performance Insights, those values represent estimates based on the ACU value for the DB instance. At the default interval of one minute, any fractional vCPU values are rounded up to the nearest whole number. For longer intervals, the vCPU value shown is the average of the integer vCPU values for each minute.

# Using Amazon Aurora Serverless v1

Amazon Aurora Serverless v1 (Amazon Aurora Serverless version 1) is an on-demand autoscaling configuration for Amazon Aurora. An *Aurora Serverless v1 DB cluster* is a DB cluster that scales compute capacity up and down based on your application's needs. This contrasts with Aurora *provisioned DB clusters*, for which you manually manage capacity. Aurora Serverless v1 provides a relatively simple, cost-effective option for infrequent, intermittent, or unpredictable workloads. It is cost-effective because it automatically starts up, scales compute capacity to match your application's usage, and shuts down when it's not in use.

To learn more about pricing, see [Serverless Pricing](#) under **MySQL-Compatible Edition** or **PostgreSQL-Compatible Edition** on the Amazon Aurora pricing page.

Aurora Serverless v1 clusters have the same kind of high-capacity, distributed, and highly available storage volume that is used by provisioned DB clusters.

For an Aurora Serverless v2 cluster, you can choose whether to encrypt the cluster volume.

For an Aurora Serverless v1 cluster, the cluster volume is always encrypted. You can choose the encryption key, but you can't disable encryption. That means that you can perform the same operations on an Aurora Serverless v1 that you can on encrypted snapshots. For more information, see [Aurora Serverless v1 and snapshots \(p. 1559\)](#).

## Topics

- [Advantages of Aurora Serverless v1 \(p. 1543\)](#)
- [Use cases for Aurora Serverless v1 \(p. 1544\)](#)
- [Limitations of Aurora Serverless v1 \(p. 1544\)](#)

- [Deleting an Aurora Serverless v1 DB cluster \(p. 1578\)](#)
- [Aurora Serverless v1 and Aurora database engine versions \(p. 1580\)](#)

## Important

Aurora has two generations of serverless technology, Aurora Serverless v2 and Aurora Serverless v1. If your application can run on MySQL 8.0 or PostgreSQL 13, we recommend that you use Aurora Serverless v2. Aurora Serverless v2 scales more quickly and in a more granular way. Aurora Serverless v2 also has more compatibility with other Aurora features such as reader DB instances. Thus, if you're already familiar with Aurora, you don't have to learn as many new procedures or limitations to use Aurora Serverless v2 as with Aurora Serverless v1. You can learn about Aurora Serverless v2 in [Using Aurora Serverless v2 \(p. 1482\)](#).

## Advantages of Aurora Serverless v1

Aurora Serverless v1 provides the following advantages:

- **Simpler than provisioned** – Aurora Serverless v1 removes much of the complexity of managing DB instances and capacity.
- **Scalable** – Aurora Serverless v1 seamlessly scales compute and memory capacity as needed, with no disruption to client connections.
- **Cost-effective** – When you use Aurora Serverless v1, you pay only for the database resources that you consume, on a per-second basis.
- **Highly available storage** – Aurora Serverless v1 uses the same fault-tolerant, distributed storage system with six-way replication as Aurora to protect against data loss.

## Use cases for Aurora Serverless v1

Aurora Serverless v1 is designed for the following use cases:

- **Infrequently used applications** – You have an application that is only used for a few minutes several times per day or week, such as a low-volume blog site. With Aurora Serverless v1, you pay for only the database resources that you consume on a per-second basis.
- **New applications** – You're deploying a new application and you're unsure about the instance size you need. By using Aurora Serverless v1, you can create a database endpoint and have the database autoscale to the capacity requirements of your application.
- **Variable workloads** – You're running a lightly used application, with peaks of 30 minutes to several hours a few times each day, or several times per year. Examples are applications for human resources, budgeting, and operational reporting applications. With Aurora Serverless v1, you no longer need to provision for peak or average capacity.
- **Unpredictable workloads** – You're running daily workloads that have sudden and unpredictable increases in activity. An example is a traffic site that sees a surge of activity when it starts raining. With Aurora Serverless v1, your database autoscales capacity to meet the needs of the application's peak load and scales back down when the surge of activity is over.
- **Development and test databases** – Your developers use databases during work hours but don't need them on nights or weekends. With Aurora Serverless v1, your database automatically shuts down when it's not in use.
- **Multi-tenant applications** – With Aurora Serverless v1, you don't have to individually manage database capacity for each application in your fleet. Aurora Serverless v1 manages individual database capacity for you.

## Limitations of Aurora Serverless v1

The following limitations apply to Aurora Serverless v1:

- Aurora Serverless v1 is available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see [Aurora Serverless v1 \(p. 32\)](#).
- Aurora Serverless v1 doesn't support the following features:
  - Aurora global databases
  - Aurora multi-master clusters
  - Aurora Replicas
  - AWS Identity and Access Management (IAM) database authentication
  - Backtracking in Aurora
  - Database activity streams
  - Performance Insights

- Viewing logs in the AWS Management Console
- Connections to an Aurora Serverless v1 DB cluster are closed automatically if held open for longer than one day.
- All Aurora Serverless v1 DB clusters have the following limitations:
  - You can't export Aurora Serverless v1 snapshots to Amazon S3 buckets.
  - You can't save data to text files in Amazon S3.
  - You can't use AWS Database Migration Service and Change Data Capture (CDC) with Aurora Serverless v1 DB clusters. Only provisioned Aurora DB clusters support CDC with AWS DMS as a source.
  - You can't load text file data to Aurora Serverless v1 from Amazon S3. However, you can load data to Aurora Serverless v1 from Amazon S3 by using the `aws_s3` extension with the `aws_s3.table_import_from_s3` function and the `credentials` parameter. For more information, see [Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster \(p. 1230\)](#).
- Aurora MySQL-based DB clusters running Aurora Serverless v1 don't support the following:
  - Invoking AWS Lambda functions from within your Aurora MySQL DB cluster. However, AWS Lambda functions can make calls to your Aurora Serverless v1 DB cluster.
  - Restoring a snapshot from a DB instance that isn't Aurora MySQL or RDS for MySQL.
  - Replicating data using replication based on binary logs (binlogs). This limitation is true regardless of whether your Aurora MySQL-based DB cluster Aurora Serverless v1 is the source or the target of the replication. To replicate data into an Aurora Serverless v1 DB cluster from a MySQL DB instance outside Aurora, such as one running on Amazon EC2, consider using AWS Database Migration Service. For more information, see the [AWS Database Migration Service User Guide](#).
  - Creating users with host-based access ('`username`'@'`IP_address`'). This is because Aurora Serverless v1 uses a router fleet between the client and the database host for seamless scaling. The IP address that the Aurora Serverless DB cluster sees is that of the router host and not your client. For more information, see [Aurora Serverless v1 architecture \(p. 1549\)](#).

Instead, use the wildcard ('`username`'@'%').

- Aurora PostgreSQL-based DB clusters running Aurora Serverless v1 have the following limitations:
  - Aurora PostgreSQL query plan management (`apg_plan_management` extension) isn't supported.
  - The logical replication feature available in Amazon RDS PostgreSQL and Aurora PostgreSQL isn't supported.
  - Outbound communications such as those enabled by Amazon RDS for PostgreSQL extensions aren't supported. For example, you can't access external data with the `postgres_fdw/dblink` extension. For more information about RDS PostgreSQL extensions, see [PostgreSQL on Amazon RDS](#) in the [RDS User Guide](#).
  - Currently, certain SQL queries and commands aren't recommended. These include session-level advisory locks, temporary relations, asynchronous notifications (`LISTEN`), and cursors with hold (`DECLARE name ... CURSOR WITH HOLD FOR query`). Also, `NOTIFY` commands prevent scaling and aren't recommended.

For more information, see [Autoscaling for Aurora Serverless v1 \(p. 1549\)](#).

- You can't set the preferred backup window for an Aurora Serverless v1 DB cluster.

## Configuration requirements for Aurora Serverless v1

When you create an Aurora Serverless v1 DB cluster, pay attention to the following requirements:

- Use these specific port numbers for each DB engine:

- Aurora MySQL – 3306
- Aurora PostgreSQL – 5432
- Create your Aurora Serverless v1 DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. When you create an Aurora Serverless v1 DB cluster in your VPC, you consume two (2) of the fifty (50) Interface and Gateway Load Balancer endpoints allotted to your VPC. These endpoints are created automatically for you. To increase your quota, you can contact AWS Support. For more information, see [Amazon VPC quotas](#).
- You can't give an Aurora Serverless v1 DB cluster a public IP address. You can access an Aurora Serverless v1 DB cluster only from within a VPC.
- Create subnets in different Availability Zones for the DB subnet group that you use for your Aurora Serverless v1 DB cluster. In other words, you can't have more than one subnet in the same Availability Zone.
- Changes to a subnet group used by an Aurora Serverless v1 DB cluster aren't applied to the cluster.
- You can access an Aurora Serverless v1 DB cluster from AWS Lambda. To do so, you must configure your Lambda function to run in the same VPC as your Aurora Serverless v1 DB cluster. For more information about working with AWS Lambda, see [Configuring a Lambda function to access resources in an Amazon VPC](#) in the *AWS Lambda Developer Guide*.

## Using TLS/SSL with Aurora Serverless v1

By default, Aurora Serverless v1 uses the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt communications between clients and your Aurora Serverless v1 DB cluster. It supports TLS/SSL versions 1.0, 1.1, and 1.2. You don't need to configure your Aurora Serverless v1 DB cluster to use TLS/SSL.

However, the following limitations apply:

- TLS/SSL support for Aurora Serverless v1 DB clusters isn't currently available in the China (Beijing) AWS Region.
- When you create database users for an Aurora MySQL-based Aurora Serverless v1 DB cluster, don't use the `REQUIRE` clause for SSL permissions. Doing so prevents users from connecting to the Aurora DB instance.
- For both MySQL Client and PostgreSQL Client utilities, session variables that you might use in other environments have no effect when using TLS/SSL between client and Aurora Serverless v1.
- For the MySQL Client, when connecting with TLS/SSL's `VERIFY_IDENTITY` mode, currently you need to use the MySQL 8.0-compatible `mysql` command. For more information, see [Connecting to a DB instance running the MySQL database engine](#).

Depending on the client that you use to connect to Aurora Serverless v1 DB cluster, you might not need to specify TLS/SSL to get an encrypted connection. For example, to use the PostgreSQL Client to connect to an Aurora Serverless v1 DB cluster running Aurora PostgreSQL-Compatible Edition, connect as you normally do.

```
psql -h endpoint -U user
```

After you enter your password, the PostgreSQL Client shows you see the connection details, including the TLS/SSL version and cipher.

```
psql (12.5 (Ubuntu 12.5-0ubuntu0.20.04.1), server 10.12)
SSL connection (protocol: TLSv1.2, cipher: ECDHE-RSA-AES256-GCM-SHA384, bits: 256,
compression: off)
```

Type "help" for help.

### Important

Aurora Serverless v1 uses the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt connections by default unless SSL/TLS is disabled by the client application. The TLS/SSL connection terminates at the router fleet. Communication between the router fleet and your Aurora Serverless v1 DB cluster occurs within the service's internal network boundary. You can check the status of the client connection to examine whether the connection to Aurora Serverless v1 is TLS/SSL encrypted. The PostgreSQL pg\_stat\_ssl and pg\_stat\_activity tables and its ssl\_is\_used function don't show the TLS/SSL state for the communication between the client application and Aurora Serverless v1. Similarly, the TLS/SSL state can't be derived from the MySQL status statement.

The Aurora cluster parameters force\_ssl for PostgreSQL and require\_secure\_transport for MySQL formerly weren't supported for Aurora Serverless v1. These parameters are available now for Aurora Serverless v1. For a complete list of parameters supported by Aurora Serverless v1, call the [DescribeEngineDefaultClusterParameters](#) API operation. For more information on parameter groups and Aurora Serverless v1, see [Parameter groups for Aurora Serverless v1 \(p. 1554\)](#).

To use the MySQL Client to connect to an Aurora Serverless v1 DB cluster running Aurora MySQL-Compatible Edition, you specify TLS/SSL in your request. The following example includes the [Amazon root CA 1 trust store](#) downloaded from Amazon Trust Services, which is necessary for this connection to succeed.

```
mysql -h endpoint -P 3306 -u user -p --ssl-ca=amazon-root-CA-1.pem --ssl-mode=REQUIRED
```

When prompted, enter your password. Soon, the MySQL monitor opens. You can confirm that the session is encrypted by using the status command.

```
mysql> status
-----
mysql Ver 14.14 Distrib 5.5.62, for Linux (x86_64) using readline 5.1
Connection id:          19
Current database:
Current user:           ****@*****
SSL:                  Cipher in use is ECDHE-RSA-AES256-SHA
...
```

To learn more about connecting to Aurora MySQL database with the MySQL Client, see [Connecting to a DB instance running the MySQL database engine](#).

Aurora Serverless v1 supports all TLS/SSL modes available to the MySQL Client (`mysql`) and PostgreSQL Client (`psql`), including those listed in the following table.

Description of TLS/SSL mode	<code>mysql</code>	<code>psql</code>
Connect without using TLS/SSL.	DISABLED	disable
Try the connection using TLS/SSL first, but fall back to non-SSL if necessary.	PREFERRED	prefer (default)
Enforce using TLS/SSL.	REQUIRED	require
Enforce TLS/SSL and verify the CA.	VERIFY_CA	verify-ca

Description of TLS/SSL mode	mysql	psql
Enforce TLS/SSL, verify the CA, and verify the CA hostname.	VERIFY_IDENTITY	verify-full

Aurora Serverless v1 uses wildcard certificates. If you specify the "verify CA" or the "verify CA and CA hostname" option when using TLS/SSL, first download the [Amazon root CA 1 trust store](#) from Amazon Trust Services. After doing so, you can identify this PEM-formatted file in your client command. To do so using the PostgreSQL Client:

For Linux, macOS, or Unix:

```
psql 'host=endpoint user=user sslmode=require sslrootcert=amazon-root-CA-1.pem dbname=db-name'
```

To learn more about working with the Aurora PostgreSQL database using the Postgres Client, see [Connecting to a DB instance running the PostgreSQL database engine](#).

For more information about connecting to Aurora DB clusters in general, see [Connecting to an Amazon Aurora DB cluster \(p. 207\)](#).

## Supported cipher suites for connections to Aurora Serverless v1 DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client TLS/SSL connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of ciphers that aren't secure or that are no longer used.

Aurora Serverless v1 DB clusters that are based on Aurora MySQL support the same cipher suites as Aurora MySQL provisioned DB clusters. For information about these cipher suites, see [Configuring cipher suites for connections to Aurora MySQL DB clusters \(p. 685\)](#).

Aurora Serverless v1 DB clusters that are based on Aurora PostgreSQL don't support cipher suites.

## How Aurora Serverless v1 works

Following, you can learn how Aurora Serverless v1 works.

## Aurora Serverless v1 architecture

The following image shows an overview of the Aurora Serverless v1 architecture.

Instead of provisioning and managing database servers, you specify Aurora capacity units (ACUs). Each ACU is a combination of approximately 2 gigabytes (GB) of memory, corresponding CPU, and networking. Database storage automatically scales from 10 gibibytes (GiB) to 128 tebibytes (TiB), the same as storage in a standard Aurora DB cluster.

You can specify the minimum and maximum ACU. The *minimum Aurora capacity unit* is the lowest ACU to which the DB cluster can scale down. The *maximum Aurora capacity unit* is the highest ACU to which the DB cluster can scale up. Based on your settings, Aurora Serverless v1 automatically creates scaling rules for thresholds for CPU utilization, connections, and available memory.

Aurora Serverless v1 manages the warm pool of resources in an AWS Region to minimize scaling time. When Aurora Serverless v1 adds new resources to the Aurora DB cluster, it uses the router fleet to switch active client connections to the new resources. At any specific time, you are charged only for the ACUs that are being actively used in your Aurora DB cluster.

## Autoscaling for Aurora Serverless v1

The capacity allocated to your Aurora Serverless v1 DB cluster seamlessly scales up and down based on the load generated by your client application. Here, load is CPU utilization and the number of connections. When capacity is constrained by either of these, Aurora Serverless v1 scales up. Aurora Serverless v1 also scales up when it detects performance issues that can be resolved by doing so.

You can view scaling events for your Aurora Serverless v1 cluster in the AWS Management Console. During autoscaling, Aurora Serverless v1 resets the `EngineUptime` metric. The value of the reset

metric value doesn't mean that seamless scaling had problems or that Aurora Serverless v1 dropped connections. It's simply the starting point for uptime at the new capacity. To learn more about metrics, see [Monitoring metrics in an Amazon Aurora cluster \(p. 427\)](#).

When your Aurora Serverless v1 DB cluster has no active connections, it can scale down to zero capacity (0 ACUs). To learn more, see [Pause and resume for Aurora Serverless v1 \(p. 1551\)](#).

When it does need to perform a scaling operation, Aurora Serverless v1 first tries to identify a *scaling point*, a moment when no queries are being processed. Aurora Serverless v1 might not be able to find a scaling point for the following reasons:

- Long-running queries
- In-progress transactions
- Temporary tables or table locks

To increase your Aurora Serverless v1 DB cluster's success rate when finding a scaling point, we recommend that you avoid long-running queries and long-running transactions. To learn more about operations that block scaling and how to avoid them, see [Best practices for working with Aurora Serverless v1](#).

By default, Aurora Serverless v1 tries to find a scaling point for 5 minutes (300 seconds). You can specify a different timeout period when you create or modify the cluster. The timeout period can be between 60 seconds and 10 minutes (600 seconds). If Aurora Serverless v1 can't find a scaling point within the specified period, the autoscaling operation times out.

By default, if autoscaling doesn't find a scaling point before timing out, Aurora Serverless v1 keeps the cluster at the current capacity. You can change this default behavior when you create or modify your Aurora Serverless v1 DB cluster by selecting the **Force the capacity change** option. For more information, see [Timeout action for capacity changes \(p. 1550\)](#).

## Timeout action for capacity changes

If autoscaling times out without finding a scaling point, by default Aurora keeps the current capacity. You can choose to have Aurora force the change by selecting the **Force the capacity change** option. This option is available in the **Autoscaling timeout and action** section of the **Create database** page when you create the cluster.

By default, the **Force the capacity change** option isn't selected. Keep this option clear to have your Aurora Serverless v1 DB cluster's capacity remain unchanged if the scaling operation times out without finding a scaling point.

Selecting this option causes your Aurora Serverless v1 DB cluster to enforce the capacity change, even without a scaling point. Before selecting this option, be aware of the consequences of this selection:

- Any in-process transactions are interrupted, and the following error message appears.

**Aurora MySQL 5.6 – ERROR 1105 (HY000):** The last transaction was aborted due to an unknown error. Please retry.

**Aurora MySQL 5.7 – ERROR 1105 (HY000):** The last transaction was aborted due to Seamless Scaling. Please retry.

You can resubmit the transactions as soon as your Aurora Serverless v1 DB cluster is available.

- Connections to temporary tables and locks are dropped.

We recommend that you select the **Force the capacity change** option only if your application can recover from dropped connections or incomplete transactions.

The choices that you make in the AWS Management Console when you create an Aurora Serverless v1 DB cluster are stored in the `ScalingConfigurationInfo` object, in the `SecondsBeforeTimeout` and `TimeoutAction` properties. The value of the `TimeoutAction` property is set to one of the following values when you create your cluster:

- `RollbackCapacityChange` – This value is set when you select the **Roll back the capacity change** option. This is the default behavior.
- `ForceApplyCapacityChange` – This value is set when you select the **Force the capacity change** option.

You can get the value of this property on an existing Aurora Serverless v1 DB cluster by using the [describe-db-clusters](#) AWS CLI command, as shown following.

For Linux, macOS, or Unix:

```
aws rds describe-db-clusters --region region \  
  --db-cluster-identifier your-cluster-name \  
  --query '*[].[ScalingConfigurationInfo:ScalingConfigurationInfo]'
```

For Windows:

```
aws rds describe-db-clusters --region region ^  
  --db-cluster-identifier your-cluster-name ^  
  --query "*[].[ScalingConfigurationInfo:ScalingConfigurationInfo]"
```

As an example, the following shows the query and response for an Aurora Serverless v1 DB cluster named `west-coast-sles` in the US West (N. California) Region.

```
$ aws rds describe-db-clusters --region us-west-1 --db-cluster-identifier west-coast-sles  
--query '*[].[ScalingConfigurationInfo:ScalingConfigurationInfo]'  
  
[  
  {  
    "ScalingConfigurationInfo": {  
      "MinCapacity": 1,  
      "MaxCapacity": 64,  
      "AutoPause": false,  
      "SecondsBeforeTimeout": 300,  
      "SecondsUntilAutoPause": 300,  
      "TimeoutAction": "RollbackCapacityChange"  
    }  
  }  
]
```

As the response shows, this Aurora Serverless v1 DB cluster uses the default setting.

For more information, see [Creating an Aurora Serverless v1 DB cluster \(p. 1559\)](#). After creating your Aurora Serverless v1, you can modify the timeout action and other capacity settings at any time. To learn how, see [Modifying an Aurora Serverless v1 DB cluster \(p. 1570\)](#).

## Pause and resume for Aurora Serverless v1

You can choose to pause your Aurora Serverless v1 DB cluster after a given amount of time with no activity. You specify the amount of time with no activity before the DB cluster is paused. When you select this option, the default inactivity time is five minutes, but you can change this value. This is an optional setting.

When the DB cluster is paused, no compute or memory activity occurs, and you are charged only for storage. If database connections are requested when an Aurora Serverless v1 DB cluster is paused, the DB cluster automatically resumes and services the connection requests.

When the DB cluster resumes activity, it has the same capacity as it had when Aurora paused the cluster. The number of ACUs depends on how much Aurora scaled the cluster up or down before pausing it.

**Note**

If a DB cluster is paused for more than seven days, the DB cluster might be backed up with a snapshot. In this case, Aurora restores the DB cluster from the snapshot when there is a request to connect to it.

## Determining the maximum number of database connections for Aurora Serverless v1

The following examples are for an Aurora Serverless v1 DB cluster that's compatible with MySQL 5.7. You can use a MySQL client or the query editor, if you've configured access to it. For more information, see [Running queries in the query editor \(p. 1614\)](#).

### To find the maximum number of database connections

- Find the capacity range for your Aurora Serverless v1 DB cluster using the AWS CLI.

```
aws rds describe-db-clusters \
--db-cluster-identifier my-serverless-57-cluster \
--query 'DBClusters[*].ScalingConfigurationInfo[0]'
```

The result shows that its capacity range is 1–4 ACUs.

```
{
  "MinCapacity": 1,
  "AutoPause": true,
  "MaxCapacity": 4,
  "TimeoutAction": "RollbackCapacityChange",
  "SecondsUntilAutoPause": 3600
}
```

- Run the following SQL query to find the maximum number of connections.

```
select @@max_connections;
```

The result shown is for the minimum capacity of the cluster, 1 ACU.

```
@@max_connections
90
```

- Scale the cluster to 8–32 ACUs.

For more information on scaling, see [Modifying an Aurora Serverless v1 DB cluster \(p. 1570\)](#).

- Confirm the capacity range.

```
{
  "MinCapacity": 8,
  "AutoPause": true,
  "MaxCapacity": 32,
  "TimeoutAction": "RollbackCapacityChange",
```

```
        "SecondsUntilAutoPause": 3600
    }
```

5. Find the maximum number of connections.

```
select @@max_connections;
```

The result shown is for the minimum capacity of the cluster, 8 ACUs.

```
@@max_connections
1000
```

6. Scale the cluster to the maximum possible, 256–256 ACUs.
7. Confirm the capacity range.

```
{
    "MinCapacity": 256,
    "AutoPause": true,
    "MaxCapacity": 256,
    "TimeoutAction": "RollbackCapacityChange",
    "SecondsUntilAutoPause": 3600
}
```

8. Find the maximum number of connections.

```
select @@max_connections;
```

The result shown is for 256 ACUs.

```
@@max_connections
6000
```

**Note**

The `max_connections` value doesn't scale linearly with the number of ACUs.

9. Scale the cluster back down to 1–4 ACUs.

```
{
    "MinCapacity": 1,
    "AutoPause": true,
    "MaxCapacity": 4,
    "TimeoutAction": "RollbackCapacityChange",
    "SecondsUntilAutoPause": 3600
}
```

This time, the `max_connections` value is for 4 ACUs.

```
@@max_connections
270
```

10. Let the cluster scale down to 2 ACUs.

```
@@max_connections
180
```

If you've configured the cluster to pause after a certain amount of time idle, it scales down to 0 ACUs. However, `max_connections` doesn't drop below the value for 1 ACU.

```
@@max_connections
90
```

## Parameter groups for Aurora Serverless v1

When you create your Aurora Serverless v1 DB cluster, you choose a specific Aurora DB engine and an associated DB cluster parameter group. Unlike provisioned Aurora DB clusters, an Aurora Serverless v1 DB cluster has a single read/write DB instance that's configured with a DB cluster parameter group only—it doesn't have a separate DB parameter group. During autoscaling, Aurora Serverless v1 needs to be able to change parameters for the cluster to work best for the increased or decreased capacity. Thus, with an Aurora Serverless v1 DB cluster, some of the changes that you might make to parameters for a particular DB engine type might not apply.

For example, an Aurora PostgreSQL-based Aurora Serverless v1 DB cluster can't use `apg_plan_mgmt.capture_plan_baselines` and other parameters that might be used on provisioned Aurora PostgreSQL DB clusters for query plan management.

You can get a list of default values for the default parameter groups for the various Aurora DB engines by using the [describe-engine-default-cluster-parameters](#) CLI command and querying the AWS Region. The following are values that you can use for the `--db-parameter-group-family` option.

Aurora MySQL 5.6	<code>aurora5.6</code>
Aurora MySQL 5.7	<code>aurora-mysql5.7</code>
Aurora PostgreSQL 10.12 (and later)	<code>aurora-postgresql10</code>

We recommend that you configure your AWS CLI with your AWS access key ID and AWS secret access key, and that you set your AWS Region before using AWS CLI commands. Providing the Region to your CLI configuration saves you from entering the `--region` parameter when running commands. To learn more about configuring AWS CLI, see [Configuration basics](#) in the *AWS Command Line Interface User Guide*.

The following example gets a list of parameters from the default DB cluster group for Aurora MySQL 5.6.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-cluster-parameters \
--db-parameter-group-family aurora5.6 --query \
'EngineDefaults.Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | [?
contains(SupportedEngineModes, `serverless`) == `true`] | [*].{param:ParameterName}' \
--output text
```

For Windows:

```
aws rds describe-engine-default-cluster-parameters ^
--db-parameter-group-family aurora5.6 --query ^
"EngineDefaults.Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | [?
contains(SupportedEngineModes, 'serverless') == 'true'] | [*].{param:ParameterName}" ^
--output text
```

## Modifying parameter values for Aurora Serverless v1

As explained in [Working with parameter groups \(p. 215\)](#), you can't directly change values in a default parameter group, regardless of its type (DB cluster parameter group, DB parameter group). Instead, you create a custom parameter group based on the default DB cluster parameter group for your Aurora DB engine and change settings as needed on that parameter group. For example, you might want to change some of the settings for your Aurora Serverless v1 DB cluster to [log queries or to upload DB engine specific logs \(p. 1556\)](#) to Amazon CloudWatch.

### To create a custom DB cluster parameter group

1. Sign in to the AWS Management Console and then open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Parameter groups**.
3. Choose **Create parameter group** to open the Parameter group details pane.
4. Choose the appropriate default DB cluster group for the DB engine you want to use for your Aurora Serverless v1 DB cluster. Be sure that you choose the following options:
  - a. For **Parameter group family**, choose the appropriate family for your chosen DB engine. Be sure that your choice has the prefix aurora- in its name.
  - b. For **Type**, choose **DB Cluster Parameter Group**.
  - c. For **Group name** and **Description**, enter meaningful names for you or others who might need to work with your Aurora Serverless v1 DB cluster and its parameters.
  - d. Choose **Create**.

Your custom DB cluster parameter group is added to the list of parameter groups available in your AWS Region. You can use your custom DB cluster parameter group when you create new Aurora Serverless v1 DB clusters. You can also modify an existing Aurora Serverless v1 DB cluster to use your custom DB cluster parameter group. After your Aurora Serverless v1 DB cluster starts using your custom DB cluster parameter group, you can change values for dynamic parameters using either the AWS Management Console or the AWS CLI.

You can also use the console to view a side-by-side comparison of the values in your custom DB cluster parameter group compared to the default DB cluster parameter group, as shown in the following screenshot.

## Parameters comparison

Parameter	my-db-cluster-param-group-for-mysql-logs	default.aurora-mysql5.7
general_log	1	<engine-default>
log_queries_not_using_indexes	1	<engine-default>
long_query_time	60	<engine-default>
server_audit_events	CONNECT	<engine-default>
server_audit_logging	1	0
server_audit_logs_upload	1	0
slow_query_log	1	<engine-default>

**Close**

When you change parameter values on an active DB cluster, Aurora Serverless v1 starts a seamless scale in order to apply the parameter changes. If your Aurora Serverless v1 DB cluster is in a paused state, it resumes and starts scaling so that it can make the change. The scaling operation for a parameter group change always [forces a capacity change \(p. 1550\)](#), so be aware that modifying parameters might result in dropped connections if a scaling point can't be found during the scaling period.

## Logging for Aurora Serverless v1

By default, error logs for Aurora Serverless v1 are enabled and automatically uploaded to Amazon CloudWatch. You can also have your Aurora Serverless v1 DB cluster upload Aurora database-engine specific logs to CloudWatch. To do this, enable configuration parameters in your custom DB cluster parameter group. Your Aurora Serverless v1 DB cluster then uploads all available logs to Amazon CloudWatch. At this point, you can use CloudWatch to analyze log data, create alarms, and view metrics.

For Aurora MySQL, you can turn on the following logs to have them automatically uploaded from your Aurora Serverless v1 DB cluster to Amazon CloudWatch.

Aurora MySQL log	Description
general_log	Creates the general log. Set to 1 to turn on. Default is off (0).
log_queries_not_using_indexes	Logs any queries to the slow query log that don't use an index. Default is off (0). Set to 1 to turn on this log.
long_query_time	Prevents fast-running queries from being logged in the slow query log. Can be set to a float between 0 and 3,1536,000. Default is 0 (not active).
server_audit_events	The list of events to capture in the logs. Supported values are CONNECT, QUERY,

Aurora MySQL log	Description
	QUERY_DCL, QUERY_DDL, QUERY_DML, and TABLE.
server_audit_logging	Set to 1 to turn on server audit logging. If you turn this on, you can specify the audit events to send to CloudWatch by listing them in the server_audit_events parameter.
slow_query_log	Creates a slow query log. Set to 1 to turn on the slow query log. Default is off (0).

For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster \(p. 823\)](#).

For Aurora PostgreSQL, you can enable the following logs on your Aurora Serverless v1 DB cluster and have them automatically uploaded to Amazon CloudWatch along with the regular error logs.

Aurora PostgreSQL log	Description
log_connections	Turned on by default and can't be changed. It logs details for all new client connections.
log_disconnections	Turned on by default and can't be changed. Logs all client disconnections.
log_lock_waits	Default is 0 (off). Set to 1 to log lock waits.
log_min_duration_statement	The minimum duration (in milliseconds) for a statement to run before it's logged.
log_min_messages	Sets the message levels that are logged. Supported values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic. To log performance data to the postgres log, set the value to debug1.
log_temp_files	Logs the use of temporary files that are above the specified kilobytes (kB).
log_statement	Controls the specific SQL statements that get logged. Supported values are none, ddl, mod, and all. Default is none.

After you turn on logs for Aurora MySQL 5.6, Aurora MySQL 5.7, or Aurora PostgreSQL for your Aurora Serverless v1 DB cluster, you can view the logs in CloudWatch.

## Viewing Aurora Serverless v1 logs with Amazon CloudWatch

Aurora Serverless v1 automatically uploads ("publishes") to Amazon CloudWatch all logs that are enabled in your custom DB cluster parameter group. You don't need to choose or specify the log types. Uploading logs starts as soon as you enable the log configuration parameter. If you later disable the log parameter, further uploads stop. However, all the logs that have already been published to CloudWatch remain until you delete them.

For more information on using CloudWatch with Aurora MySQL logs, see [Monitoring log events in Amazon CloudWatch \(p. 927\)](#).

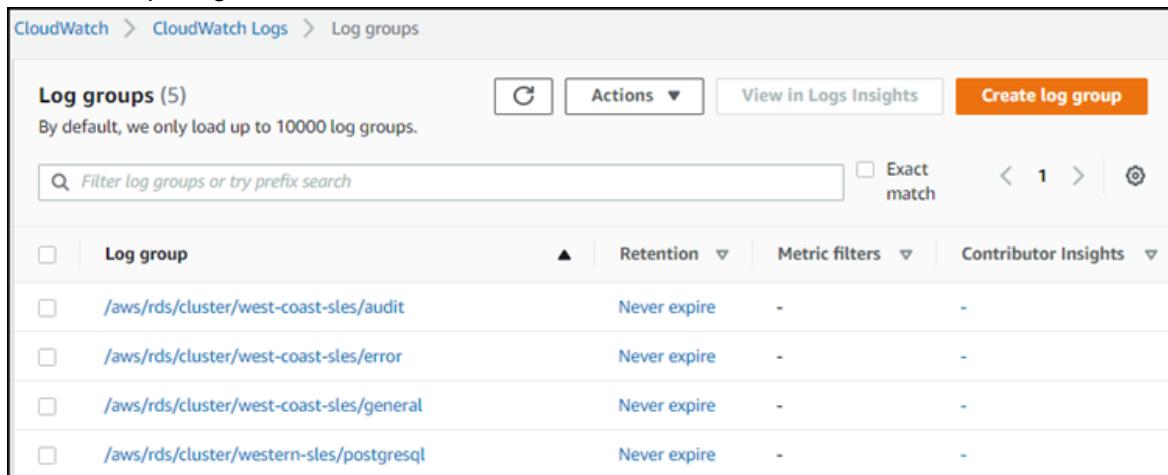

For more information about CloudWatch and Aurora PostgreSQL, see [Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs \(p. 1265\)](#).

### To view logs for your Aurora Serverless v1 DB cluster

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Choose your AWS Region.
3. Choose **Log groups**.
4. Choose your Aurora Serverless v1 DB cluster log from the list. For error logs, the naming pattern is as follows.

/aws/rds/cluster/*cluster-name*/error

For example, in the following screenshot you can find listings for logs published for an Aurora PostgreSQL Aurora Serverless v1 DB cluster named `western-sles`. You can also find several listings for Aurora MySQL Aurora Serverless v1 DB cluster, `west-coast-sles`. Choose the log that you're interested in to start exploring its content.

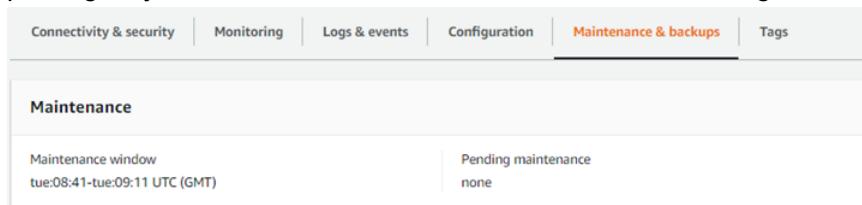

The screenshot shows the AWS CloudWatch Log Groups interface. At the top, there are navigation links: CloudWatch > CloudWatch Logs > Log groups. Below this is a search bar labeled "Filter log groups or try prefix search". To the right of the search bar are buttons for "Actions", "View in Logs Insights", and "Create log group". A checkbox labeled "Exact match" is checked. The main area displays a table of log groups:

<input type="checkbox"/>	Log group	Retention	Metric filters	Contributor Insights
<input type="checkbox"/>	/aws/rds/cluster/west-coast-sles/audit	Never expire	-	-
<input type="checkbox"/>	/aws/rds/cluster/west-coast-sles/error	Never expire	-	-
<input type="checkbox"/>	/aws/rds/cluster/west-coast-sles/general	Never expire	-	-
<input type="checkbox"/>	/aws/rds/cluster/western-sles/postgresql	Never expire	-	-

## Aurora Serverless v1 and maintenance

Maintenance for Aurora Serverless v1 DB cluster, such as applying the latest features, fixes, and security updates, is performed automatically for you. Unlike provisioned Aurora DB clusters, Aurora Serverless v1 doesn't have user-settable maintenance windows. However, it does have a maintenance window that you can view in the AWS Management Console in **Maintenance & backups** for your Aurora Serverless v1 DB cluster. You can find the date and time that maintenance might be performed and if any maintenance is pending for your Aurora Serverless v1 DB cluster, as shown following.

The screenshot shows the "Maintenance & backups" tab selected in the AWS Management Console. The interface includes tabs for Connectivity & security, Monitoring, Logs & events, Configuration, Maintenance & backups (which is highlighted), and Tags. Below the tabs, there is a section titled "Maintenance" with the following details:

Maintenance window	Pending maintenance
tue:08:41-tue:09:11 UTC (GMT)	none

Whenever possible, Aurora Serverless v1 performs maintenance in a nondisruptive manner. When maintenance is required, your Aurora Serverless v1 DB cluster scales its capacity to handle the necessary

operations. Before scaling, Aurora Serverless v1 looks for a scaling point. It does so for up to seven days if necessary.

At the end of each day that Aurora Serverless v1 can't find a scaling point, it creates a cluster event. This event notifies you of the pending maintenance and the need to scale to perform maintenance. The notification includes the date when Aurora Serverless v1 can force the DB cluster to scale.

Until that time, your Aurora Serverless v1 DB cluster continues looking for a scaling point and behaves according to its `TimeoutAction` setting. That is, if it can't find a scaling point before timing out, it abandons the capacity change if it's configured to `RollbackCapacityChange`. Or it forces the change if it's set to `ForceApplyCapacityChange`. As with any change that's forced without an appropriate scaling point, this might interrupt your workload.

For more information, see [Timeout action for capacity changes \(p. 1550\)](#).

## Aurora Serverless v1 and failover

If the DB instance for an Aurora Serverless v1 DB cluster becomes unavailable or the Availability Zone (AZ) it's in fails, Aurora recreates the DB instance in a different AZ. However, the Aurora Serverless v1 cluster isn't a Multi-AZ cluster. That's because it consists of a single DB instance in a single AZ. Thus, this failover mechanism takes longer than for an Aurora cluster with provisioned or Aurora Serverless v2 instances. The Aurora Serverless v1 failover time is undefined because it depends on demand and capacity availability in other AZs within the given AWS Region.

Because Aurora separates computation capacity and storage, the storage volume for the cluster is spread across multiple AZs. Your data remains available even if outages affect the DB instance or the associated AZ.

## Aurora Serverless v1 and snapshots

The cluster volume for an Aurora Serverless v1 cluster is always encrypted. You can choose the encryption key, but you can't disable encryption. To copy or share a snapshot of an Aurora Serverless v1 cluster, encrypt the snapshot using your own AWS KMS key. For more information, see [Copying a DB cluster snapshot \(p. 378\)](#). To learn more about encryption and Amazon Aurora, see [Encrypting an Amazon Aurora DB cluster \(p. 1638\)](#)

## Creating an Aurora Serverless v1 DB cluster

The following procedure creates an Aurora Serverless v1 cluster without any of your schema objects or data. If you want to create an Aurora Serverless v1 cluster that's a duplicate of an existing provisioned or Aurora Serverless v1 cluster, you can perform a snapshot restore or cloning operation instead. For those details, see [Restoring from a DB cluster snapshot \(p. 375\)](#) and [Cloning a volume for an Amazon Aurora DB cluster \(p. 280\)](#). You can't convert an existing provisioned cluster to Aurora Serverless v1. You also can't convert an existing Aurora Serverless v1 cluster back to a provisioned cluster.

When you create an Aurora Serverless v1 DB cluster, you can set the minimum and maximum capacity for the cluster. A capacity unit is equivalent to a specific compute and memory configuration. Aurora Serverless v1 creates scaling rules for thresholds for CPU utilization, connections, and available memory and seamlessly scales to a range of capacity units as needed for your applications. For more information see [Aurora Serverless v1 architecture \(p. 1549\)](#).

You can set the following specific values for your Aurora Serverless v1 DB cluster:

- **Minimum Aurora capacity unit** – Aurora Serverless v1 can reduce capacity down to this capacity unit.

- **Maximum Aurora capacity unit** – Aurora Serverless v1 can increase capacity up to this capacity unit.

You can also choose the following optional scaling configuration options:

- **Force scaling the capacity to the specified values when the timeout is reached** – You can choose this setting if you want Aurora Serverless v1 to force Aurora Serverless v1 to scale even if it can't find a scaling point before it times out. If you want Aurora Serverless v1 to cancel capacity changes if it can't find a scaling point, don't choose this setting. For more information, see [Timeout action for capacity changes \(p. 1550\)](#).
- **Pause compute capacity after consecutive minutes of inactivity** – You can choose this setting if you want Aurora Serverless v1 to scale to zero when there's no activity on your DB cluster for an amount of time you specify. With this setting enabled, your Aurora Serverless v1 DB cluster automatically resumes processing and scales to the necessary capacity to handle the workload when database traffic resumes. To learn more, see [Pause and resume for Aurora Serverless v1 \(p. 1551\)](#).

Before you can create an Aurora Serverless v1 DB cluster, you need an AWS account. You also need to have completed the setup tasks for working with Amazon Aurora. For more information, see [Setting up your environment for Amazon Aurora \(p. 87\)](#). You also need to complete other preliminary steps for creating any Aurora DB cluster. To learn more, see [Creating an Amazon Aurora DB cluster \(p. 127\)](#).

Aurora Serverless v1 is available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see [Aurora Serverless v1 \(p. 32\)](#).

**Note**

The cluster volume for an Aurora Serverless v1 cluster is always encrypted. When you create your Aurora Serverless v1 DB cluster, you can't turn off encryption, but you can choose to use your own encryption key. With Aurora Serverless v2, you can choose whether to encrypt the cluster volume.

You can create an Aurora Serverless v1 DB cluster with the AWS Management Console, the AWS CLI, or the RDS API.

**Note**

If you receive the following error message when trying to create your cluster, your account needs additional permissions.

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.

See [Using service-linked roles for Amazon Aurora \(p. 1724\)](#) for more information.

You can't directly connect to the DB instance on your Aurora Serverless v1 DB cluster. To connect to your Aurora Serverless v1 DB cluster, you use the database endpoint. You can find the endpoint for your Aurora Serverless v1 DB cluster on the **Connectivity & security** tab for your cluster in the AWS Management Console. For more information, see [Connecting to an Amazon Aurora DB cluster \(p. 207\)](#).

## Console

Use the following general procedure. For more information on creating an Aurora DB cluster using the AWS Management Console, see [Creating an Amazon Aurora DB cluster \(p. 127\)](#).

### To create a new Aurora Serverless v1 DB cluster

1. Sign in to the AWS Management Console.
2. Choose an AWS Region that supports Aurora Serverless v1.
3. Choose Amazon RDS from the AWS Services list.
4. Choose **Create database**.

5. On the **Create database** page:
  - a. Choose **Standard Create** for the database creation method.
  - b. Choose **Amazon Aurora** for the Engine type in the **Engine options** section.
  - c. Choose **Amazon Aurora with MySQL compatibility** or **Amazon Aurora with PostgreSQL compatibility**, and continue creating the Aurora Serverless v1 DB cluster by using the steps from the following examples.

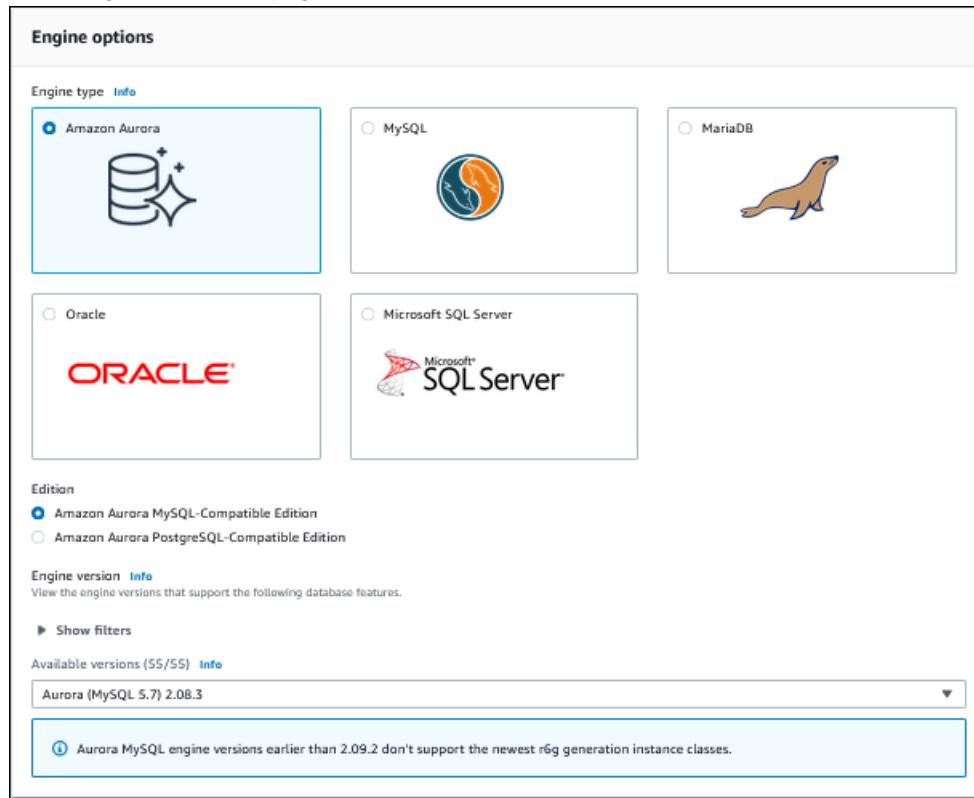

If you choose a version of the DB engine that doesn't support Aurora Serverless v1, the **Serverless** option doesn't display.

## Example for Aurora MySQL

Use the following procedure.

### To create an Aurora Serverless v1 DB cluster for Aurora MySQL

1. Choose **Amazon Aurora with MySQL Compatibility** for the Edition.
2. Choose the Aurora MySQL version you want for your DB cluster. The supported versions are shown on the right side of the page.

3. For **DB instance class**, confirm that **Serverless** is chosen.
4. Set the **Capacity range** for the DB cluster.
5. Adjust values as needed in the **Additional scaling configuration** section of the page. To learn more about capacity settings, see [Autoscaling for Aurora Serverless v1 \(p. 1549\)](#).

**Instance configuration**

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class [Info](#)

Serverless

Memory optimized classes (includes r classes)

Burstable classes (includes t classes)

Serverless v1  
The previous generation of Aurora Serverless.

Include previous generation classes

Capacity range [Info](#)

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs

1 ACU  
2 GiB RAM

Maximum ACUs

64 ACU  
122 GiB RAM

▼ Additional scaling configuration

Autoscaling timeout and action [Info](#)

Specify the amount of time to allow Aurora to look for a scaling point before the timeout action.

00:05:00

Max: 10 minutes. Min: 1 minute.

If the timeout expires before a scaling point is found, do this:

Roll back the capacity change  
Your Aurora Serverless cluster's capacity isn't changed. It stays as its current capacity.

Force the capacity change  
Your Aurora Serverless cluster's capacity is changed without a scaling point. This can interrupt in-progress transactions, requiring resubmission.

Pause after inactivity [Info](#)

Scale the capacity to 0 ACUs when cluster is idle  
This optional setting allows your Aurora Serverless cluster to scale its capacity to 0 ACUs while inactive. When database traffic resumes, your Aurora Serverless cluster resumes processing capacity and scales to handle the traffic.

6. To enable the Data API for your Aurora Serverless v1 DB cluster, select the **Data API** check box under **Additional configuration** in the **Connectivity** section.

To learn more about the Data API, see [Using the Data API for Aurora Serverless v1 \(p. 1581\)](#).

7. Choose other database settings as needed, then choose **Create database**.

## Example for Aurora PostgreSQL

Use the following procedure.

### To create an Aurora Serverless v1 DB cluster for Aurora PostgreSQL

1. Choose **Amazon Aurora with Postgres; Compatibility** for the Edition.
2. Choose the Aurora PostgreSQL version you want for your DB cluster. The supported versions are shown on the right side of the page.

**Engine options**

Engine type [Info](#)

Amazon Aurora 

MySQL 

MariaDB 

PostgreSQL 

Oracle 

Microsoft SQL Server 

Edition

Amazon Aurora MySQL-Compatible Edition

Amazon Aurora PostgreSQL-Compatible Edition

Engine version [Info](#)

**Serverless v1**  
The previous generation of Aurora Serverless.

Include previous generation classes

**Capacity range** [Info](#)

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

**Minimum ACUs** **Maximum ACUs**

2 ACU 384 ACU  
4 GiB RAM 768GB RAM

**Additional scaling configuration**

**Autoscaling timeout and action** [Info](#)

Specify the amount of time to allow Aurora to look for a scaling point before the timeout action.

00:05:00

Max: 10 minutes. Min: 1 minute.

If the timeout expires before a scaling point is found, do this:

Roll back the capacity change  
Your Aurora Serverless cluster's capacity isn't changed. It stays as its current capacity.

Force the capacity change  
Your Aurora Serverless cluster's capacity is changed without a scaling point. This can interrupt in-progress transactions, requiring resubmission.

**Pause after inactivity** [Info](#)

Scale the capacity to 0 ACUs when cluster is idle  
This optional setting allows your Aurora Serverless cluster to scale its capacity to 0 ACUs while inactive. When database traffic resumes, your Aurora Serverless cluster resumes processing capacity and scales to handle the traffic.

6. To enable the Data API for your Aurora Serverless v1 DB cluster, select the **Data API** check box under **Additional configuration** in the **Connectivity** section.  
To learn more about the Data API, see [Using the Data API for Aurora Serverless v1 \(p. 1581\)](#).
7. Choose other database settings as needed, then choose **Create database**.

## AWS CLI

To create a new Aurora Serverless v1 DB cluster with the AWS CLI, run the `create-db-cluster` command and specify `serverless` for the `--engine-mode` option.

You can optionally specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections.

The following command examples create a new Serverless DB cluster by setting the `--engine-mode` option to `serverless`. The examples also specify values for the `--scaling-configuration` option.

### Example for Aurora MySQL

The following commands create new MySQL-compatible Serverless DB clusters. Valid capacity values for Aurora MySQL are 1, 2, 4, 8, 16, 32, 64, 128, and 256.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora --engine-version 5.6.mysql_aurora.1.22.3 \
--engine-mode serverless --scaling-configuration
MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true \
--master-username username --master-user-password password

aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.3 \
--engine-mode serverless --scaling-configuration
MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true \
--master-username username --master-user-password password
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora --engine-version 5.6.mysql_aurora.1.22.3 ^
--engine-mode serverless --scaling-configuration
MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true ^
--master-username username --master-user-password password

aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.3 ^
--engine-mode serverless --scaling-configuration
MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true ^
--master-username username --master-user-password password
```

## Example for Aurora PostgreSQL

The following command creates a new PostgreSQL 10.12–compatible Serverless DB cluster. Valid capacity values for Aurora PostgreSQL are 2, 4, 8, 16, 32, 64, 192, and 384.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-postgresql
--engine-version 10.12 \
--engine-mode serverless --scaling-configuration
MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=1000,AutoPause=true \
--master-username username --master-user-password password
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-postgresql
--engine-version 10.12 ^
--engine-mode serverless --scaling-configuration
MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=1000,AutoPause=true ^
--master-username username --master-user-password password
```

## RDS API

To create a new Aurora Serverless v1 DB cluster with the RDS API, run the [CreateDBCluster](#) operation and specify `serverless` for the `EngineMode` parameter.

You can optionally specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

## Restoring an Aurora Serverless v1 DB cluster

You can configure an Aurora Serverless v1 DB cluster when you restore a provisioned DB cluster snapshot with the AWS Management Console, the AWS CLI, or the RDS API.

When you restore a snapshot to an Aurora Serverless v1 DB cluster, you can set the following specific values:

- **Minimum Aurora capacity unit** – Aurora Serverless v1 can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless v1 can increase capacity up to this capacity unit.
- **Timeout action** – The action to take when a capacity modification times out because it can't find a scaling point. Aurora Serverless v1 DB cluster can force your DB cluster to the new capacity settings if set the **Force scaling the capacity to the specified values...** option. Or, it can roll back the capacity change to cancel it if you don't choose the option. For more information, see [Timeout action for capacity changes \(p. 1550\)](#).
- **Pause after inactivity** – The amount of time with no database traffic to scale to zero processing capacity. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

For general information about restoring a DB cluster from a snapshot, see [Restoring from a DB cluster snapshot \(p. 375\)](#).

## Console

You can restore a DB cluster snapshot to an Aurora DB cluster with the AWS Management Console.

### To restore a DB cluster snapshot to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region that hosts your source DB cluster.
3. In the navigation pane, choose **Snapshots**, and choose the DB cluster snapshot that you want to restore.
4. For **Actions**, choose **Restore Snapshot**.
5. On the **Restore DB Cluster** page, choose **Serverless** for **Capacity type**.

## Restore DB Cluster

### Instance specifications

#### DB Engine

Name of the Database Engine

Aurora MySQL

#### DB Engine Version

Version Number of the Database Engine to be used for this instance

Aurora (MySQL)-5.6.10a (default)

#### Capacity type [Info](#)

**Provisioned**

You provision and manage the server instance sizes.

**Serverless [Info](#)**

You specify the minimum and maximum of resources for a DB cluster. Aurora scales the capacity based on database load (currently available for Aurora MySQL 5.6).

6. In the **DB cluster identifier** field, type the name for your restored DB cluster, and complete the other fields.
7. In the **Capacity settings** section, modify the scaling configuration.

**Instance configuration**  
The DB instance configuration options below are limited to those supported by the engine that you selected above.

**DB instance class** [Info](#)  
 Serverless  
 Memory optimized classes (includes r classes)  
 Burstable classes (includes t classes)

**Serverless v1**  
The previous generation of Aurora Serverless.  
 Include previous generation classes

**Capacity range** [Info](#)  
Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

**Minimum ACUs**  
1 ACU  
2 GiB RAM

**Maximum ACUs**  
64 ACU  
122 GiB RAM

**▼ Additional scaling configuration**

**Autoscaling timeout and action** [Info](#)  
Specify the amount of time to allow Aurora to look for a scaling point before the timeout action.  
00:05:00  
Max: 10 minutes. Min: 1 minute.

If the timeout expires before a scaling point is found, do this:

Roll back the capacity change  
Your Aurora Serverless cluster's capacity isn't changed. It stays as its current capacity.

Force the capacity change  
Your Aurora Serverless cluster's capacity is changed without a scaling point. This can interrupt in-progress transactions, requiring resubmission.

**Pause after inactivity** [Info](#)  
 Scale the capacity to 0 ACUs when cluster is idle  
This optional setting allows your Aurora Serverless cluster to scale its capacity to 0 ACUs while inactive. When database traffic resumes, your Aurora Serverless cluster resumes processing capacity and scales to handle the traffic.

## 8. Choose Restore DB Cluster.

To connect to an Aurora Serverless v1 DB cluster, use the database endpoint. For details, see the instructions in [Connecting to an Amazon Aurora DB cluster \(p. 207\)](#).

### Note

If you encounter the following error message, your account requires additional permissions:  
Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.  
For more information, see [Using service-linked roles for Amazon Aurora \(p. 1724\)](#).

## AWS CLI

You can configure an Aurora Serverless DB cluster when you restore a provisioned DB cluster snapshot with the AWS Management Console, the AWS CLI, or the RDS API.

When you restore a snapshot to an Aurora Serverless DB cluster, you can set the following specific values:

- **Minimum Aurora capacity unit** – Aurora Serverless can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless can increase capacity up to this capacity unit.
- **Timeout action** – The action to take when a capacity modification times out because it can't find a scaling point. Aurora Serverless v1 DB cluster can force your DB cluster to the new capacity settings if set the **Force scaling the capacity to the specified values...** option. Or, it can roll back the capacity

change to cancel it if you don't choose the option. For more information, see [Timeout action for capacity changes \(p. 1550\)](#).

- **Pause after inactivity** – The amount of time with no database traffic to scale to zero processing capacity. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

**Note**

The version of the DB cluster snapshot must be compatible with Aurora Serverless v1. For the list of supported versions, see [Aurora Serverless v1 \(p. 32\)](#).

To restore a snapshot to an Aurora Serverless v1 cluster with MySQL 5.7 compatibility, include the following additional parameters:

- `--engine aurora-mysql`
- `--engine-version 5.7`

The `--engine` and `--engine-version` parameters let you create a MySQL 5.7-compatible Aurora Serverless v1 cluster from a MySQL 5.6-compatible Aurora or Aurora Serverless v1 snapshot. The following example restores a snapshot from a MySQL 5.6-compatible cluster named `mydbclustersnapshot` to a MySQL 5.7-compatible Aurora Serverless v1 cluster named `mynewdbcluster`.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
  --db-cluster-identifier mynewdbcluster \
  --snapshot-identifier mydbclustersnapshot \
  --engine-mode serverless \
  --engine aurora-mysql \
  --engine-version 5.7
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
  --db-instance-identifier mynewdbcluster ^
  --db-snapshot-identifier mydbclustersnapshot ^
  --engine aurora-mysql ^
  --engine-version 5.7
```

You can optionally specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In the following example, you restore from a previously created DB cluster snapshot named `mydbclustersnapshot` to a new DB cluster named `mynewdbcluster`. You set the `--scaling-configuration` so that the new Aurora Serverless v1 DB cluster can scale from 8 ACUs to 64 ACUs (Aurora capacity units) as needed to process the workload. After processing completes and after 1000 seconds with no connections to support, the cluster shuts down until connection requests prompt it to restart.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
```

```
--db-cluster-identifier mynewdbcluster \
--snapshot-identifier mydbclustersnapshot \
--engine-mode serverless --scaling-configuration
MinCapacity=8,MaxCapacity=64,TimeoutAction='ForceApplyCapacityChange',SecondsUntilAutoPause=1000,AutoP
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
--db-instance-identifier mynewdbcluster ^
--db-snapshot-identifier mydbclustersnapshot ^
--engine-mode serverless --scaling-configuration
MinCapacity=8,MaxCapacity=64,TimeoutAction='ForceApplyCapacityChange',SecondsUntilAutoPause=1000,AutoP
```

## RDS API

To configure an Aurora Serverless v1 DB cluster when you restore from a DB cluster using the RDS API, run the [RestoreDBClusterFromSnapshot](#) operation and specify `serverless` for the `EngineMode` parameter.

You can optionally specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

## Modifying an Aurora Serverless v1 DB cluster

After you configure an Aurora Serverless v1 DB cluster, you can modify certain properties with the AWS Management Console, the AWS CLI, or the RDS API. Most of the properties you can modify are the same as for other kinds of Aurora clusters. The properties that are most relevant for Aurora Serverless v1 are the scaling configuration of the cluster, and the major version for Aurora Serverless v1 clusters that are compatible with MySQL 5.6 and PostgreSQL 10.

You can set the minimum and maximum capacity for the DB cluster. Each capacity unit is equivalent to a specific compute and memory configuration. Aurora Serverless automatically creates scaling rules for thresholds for CPU utilization, connections, and available memory. You can also set whether Aurora Serverless pauses the database when there's no activity and then resumes when activity begins again.

You can set the following specific values for the scaling configuration:

- **Minimum Aurora capacity unit** – Aurora Serverless can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless can increase capacity up to this capacity unit.
- **Autoscaling timeout and action** – This section specifies how long Aurora Serverless waits to find a scaling point before timing out. It also specifies the action to take when a capacity modification times out because it can't find a scaling point. Aurora can force the capacity change to set the capacity to the specified value as soon as possible. Or, it can roll back the capacity change to cancel it. For more information, see [Timeout action for capacity changes \(p. 1550\)](#).
- **Pause after inactivity** – The amount of time with no database traffic to scale to zero processing capacity. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

You can choose the major version for certain Aurora Serverless v1 DB clusters:

- DB clusters compatible with MySQL 5.6 – Choose a corresponding MySQL 5.7–compatible version number.
- DB clusters compatible with PostgreSQL 10 – Choose a corresponding PostgreSQL 11–compatible version number.

Doing so performs an in-place upgrade of the Aurora Serverless v1 DB cluster.

## Console

You can modify the scaling configuration of an Aurora DB cluster with the AWS Management Console.

### To modify an Aurora Serverless v1 DB cluster

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora Serverless v1 DB cluster that you want to modify.
4. For **Actions**, choose **Modify cluster**.
5. For **Version**:
  - Choose an Aurora MySQL version 2 version number if you want to perform an in-place upgrade from a MySQL 5.6–compatible cluster to a MySQL 5.7–compatible one.
  - Choose an Aurora PostgreSQL version 11 version number if you want to perform an in-place upgrade from a PostgreSQL 10–compatible cluster to a PostgreSQL 11–compatible one.

The following example shows an in-place upgrade from Aurora MySQL 1.22.3 to 2.08.3.

The screenshot shows the 'Modify DB cluster' page for a MySQL database cluster named 'serverless-v1-ams-cluster'. The 'Version' section lists three options: 'Aurora MySQL (compatible with MySQL 5.6.1.22.3)' (selected), 'Aurora MySQL (compatible with MySQL 5.6.1.22.3)', and 'Aurora MySQL (compatible with MySQL 5.7.2.08.3)'. A note at the bottom of this section says 'To avoid a required upgrade soon, choose Aurora MySQL version 2 or higher.' The 'DB cluster identifier' field contains 'serverless-v1-ams-cluster'. The 'New master password' field is empty. In the 'Capacity settings' section, the 'Minimum Aurora capacity units' is set to '1 ACU' (2 GB RAM) and the 'Maximum Aurora capacity units' is set to '16 ACU' (32 GB RAM). The 'Additional scaling configuration' section is collapsed. The 'Connectivity' section shows a VPC security group named 'default' selected from a dropdown menu. The 'Web Service Data API' section has a checked checkbox for 'Data API' with a note explaining it enables the SQL HTTP endpoint for running SQL queries. The 'Additional configuration' section is collapsed. At the bottom right, there are 'Cancel' and 'Continue' buttons.

If you perform a major version upgrade, leave all the other properties the same. To change any of the other properties, do another **Modify** operation after the upgrade finishes.

6. In the **Capacity settings** section, modify the scaling configuration.
7. Choose **Continue**.
8. On the **Modify DB cluster** page, review your modifications, then choose one of the following:
  - **Apply during the next scheduled maintenance window**
  - **Apply immediately**
9. Choose **Modify cluster**.

## AWS CLI

To modify the scaling configuration of an Aurora Serverless v1 DB cluster using the AWS CLI, run the `modify-db-cluster` AWS CLI command. Specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In this example, you modify the scaling configuration of an Aurora Serverless v1 DB cluster named *sample-cluster*.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier sample-cluster \
    --scaling-configuration
    MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=500,TimeoutAction='ForceApplyCapacityChange',AutoPa
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier sample-cluster ^
    --scaling-configuration
    MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=500,TimeoutAction='ForceApplyCapacityChange',AutoPa
```

To perform an in-place upgrade from a MySQL 5.6-compatible Aurora Serverless v1 DB cluster to a MySQL 5.7-compatible one, specify the `--engine-version` parameter with an Aurora MySQL version 2 version number that's compatible with Aurora Serverless v1. Also include the `--allow-major-version-upgrade` parameter.

In this example, you modify the major version of a MySQL 5.6-compatible Aurora Serverless v1 DB cluster named *sample-cluster*. Doing so performs an in-place upgrade to a MySQL 5.7-compatible Aurora Serverless v1 DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier sample-cluster \
    --engine-version 5.7.mysql_aurora.2.08.3 \
    --allow-major-version-upgrade
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier sample-cluster ^
    --engine-version 5.7.mysql_aurora.2.08.3 ^
    --allow-major-version-upgrade
```

To perform an in-place upgrade from a PostgreSQL 10-compatible Aurora Serverless v1 DB cluster to a PostgreSQL 11-compatible one, specify the `--engine-version` parameter with an Aurora PostgreSQL version 11 version number that's compatible with Aurora Serverless v1. Also include the `--allow-major-version-upgrade` parameter.

In this example, you modify the major version of a PostgreSQL 10-compatible Aurora Serverless v1 DB cluster named *sample-cluster*. Doing so performs an in-place upgrade to a PostgreSQL 11-compatible Aurora Serverless v1 DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier sample-cluster \
```

```
--engine-version 11.13 \
--allow-major-version-upgrade
```

For Windows:

```
aws rds modify-db-cluster ^
--db-cluster-identifier sample-cluster ^
--engine-version 11.13 ^
--allow-major-version-upgrade
```

## RDS API

You can modify the scaling configuration of an Aurora DB cluster with the [ModifyDBCluster](#) API operation. Specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

To perform an in-place upgrade from a MySQL 5.6-compatible Aurora Serverless v1 DB cluster to a MySQL 5.7-compatible one, specify the `EngineVersion` parameter with an Aurora MySQL version 2 version number that's compatible with Aurora Serverless v1. Also include the `AllowMajorVersionUpgrade` parameter.

To perform an in-place upgrade from a PostgreSQL 10-compatible Aurora Serverless v1 DB cluster to a PostgreSQL 11-compatible one, specify the `EngineVersion` parameter with an Aurora PostgreSQL version 11 version number that's compatible with Aurora Serverless v1. Also include the `AllowMajorVersionUpgrade` parameter.

# Scaling Aurora Serverless v1 DB cluster capacity manually

Typically, Aurora Serverless v1 DB clusters scale seamlessly based on the workload. However, capacity might not always scale fast enough to meet sudden extremes, such as an exponential increase in transactions. In such cases you can initiate the scaling operation manually by setting a new capacity value. After you set the capacity explicitly, Aurora Serverless v1 automatically scales the DB cluster. It does so based on the cooldown period for scaling down.

You can explicitly set the capacity of an Aurora Serverless v1 DB cluster to a specific value with the AWS Management Console, the AWS CLI, or the RDS API.

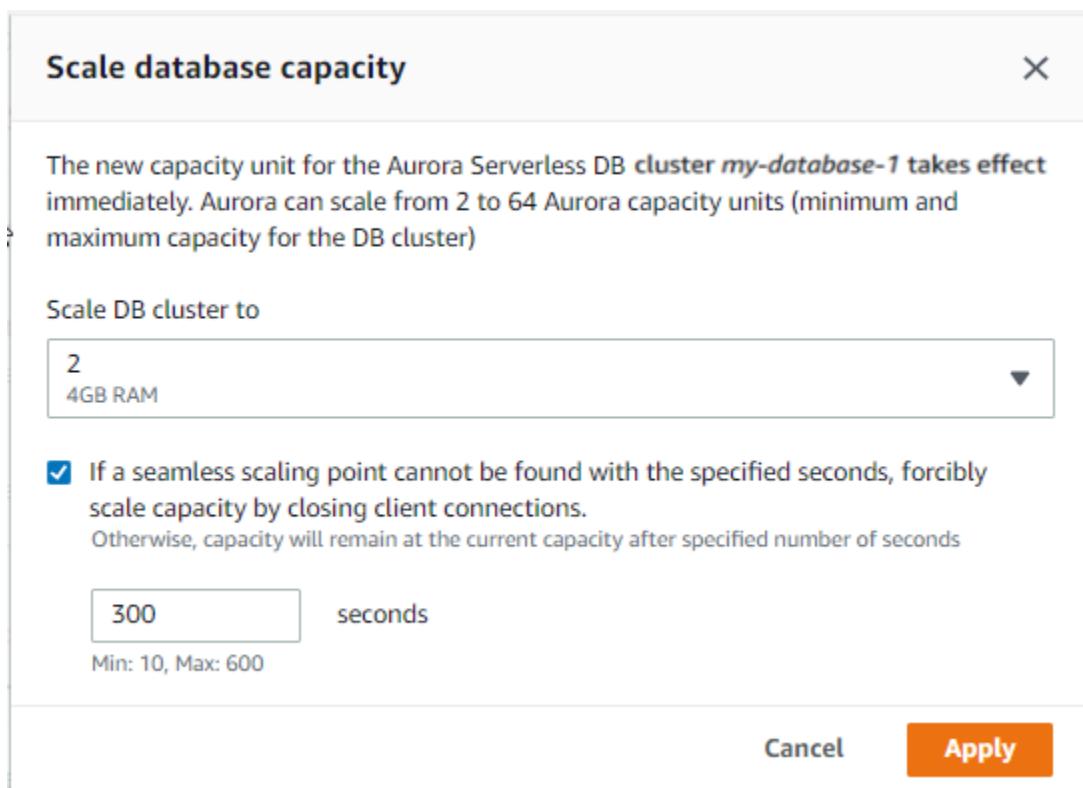

## Console

You can set the capacity of an Aurora DB cluster with the AWS Management Console.

### To modify an Aurora Serverless v1 DB cluster

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora Serverless v1 DB cluster that you want to modify.

4. For **Actions**, choose **Set capacity**.
5. In the **Scale database capacity** window, choose the following:
  - a. For the **Scale DB cluster to** drop-down selector, choose the new capacity that you want for your DB cluster.
  - b. For the **If a seamless scaling point cannot be found** check box, choose the behavior that you want for your Aurora Serverless v1 DB cluster's `TimeoutAction` setting, as follows:
    - Clear this option if you want your capacity to remain unchanged if Aurora Serverless v1 can't find a scaling point before timing out.
    - Select this option if you want to force your Aurora Serverless v1 DB cluster change its capacity even if it can't find a scaling point before timing out. This option can result Aurora Serverless v1 dropping connections that prevent it from finding a scaling point.
  - c. For **seconds**, enter the amount of time you want to allow your Aurora Serverless v1 DB cluster to look for a scaling point before timing out. You can specify anywhere from 10 seconds to 600 seconds (10 minutes). The default is five minutes (300 seconds). This following example forces the Aurora Serverless v1 DB cluster to scale down to 2 ACUs even if it can't find a scaling point within five minutes.

6. Choose **Apply**.

To learn more about scaling points, `TimeoutAction`, and cooldown periods, see [Autoscaling for Aurora Serverless v1 \(p. 1549\)](#).

## AWS CLI

To set the capacity of an Aurora Serverless v1 DB cluster using the AWS CLI, run the [modify-current-db-cluster-capacity](#) AWS CLI command, and specify the `--capacity` option. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In this example, you set the capacity of an Aurora Serverless v1 DB cluster named `sample-cluster` to 64.

```
aws rds modify-current-db-cluster-capacity --db-cluster-identifier sample-cluster --capacity 64
```

## RDS API

You can set the capacity of an Aurora DB cluster with the [ModifyCurrentDBClusterCapacity](#) API operation. Specify the `Capacity` parameter. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

# Viewing Aurora Serverless v1 DB clusters

After you create one or more Aurora Serverless v1 DB clusters, you can view which DB clusters are type **Serverless** and which are type **Instance**. You can also view the current number of Aurora capacity units (ACUs) each Aurora Serverless v1 DB cluster is using. Each ACU is a combination of processing (CPU) and memory (RAM) capacity.

### To view your Aurora Serverless v1 DB clusters

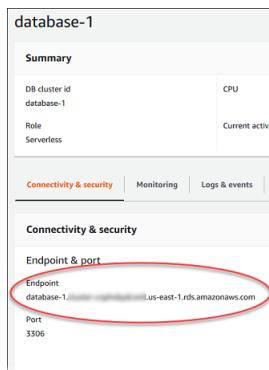

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the Aurora Serverless v1 DB clusters.
3. In the navigation pane, choose **Databases**.

For each DB cluster, the DB cluster type is shown under **Role**. The Aurora Serverless v1 DB clusters show **Serverless** for the type. You can view an Aurora Serverless v1 DB cluster's current capacity under **Size**.

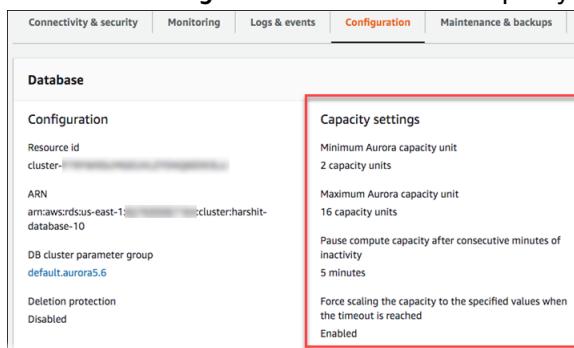

DB identifier	Role	Engine	Region & AZ	Size	Status
database-1	Serverless	Aurora MySQL	us-east-1	0 capacity units	<span>Green</span>
my-database-1	Serverless	Aurora PostgreSQL	us-east-1	0 capacity units	<span>Green</span>
mysqls3	Instance	MySQL	us-east-1c	db.t3.medium	<span>Green</span>
testsAurora	Regional	Aurora MySQL	us-east-1	2 instances	<span>Green</span>
testsAurora	Writer	Aurora MySQL	us-east-1a	db.t3.medium	<span>Green</span>
testsAurora-us-east-1b	Reader	Aurora MySQL	us-east-1b	db.t3.medium	<span>Green</span>

4. Choose the name of an Aurora Serverless v1 DB cluster to display its details.

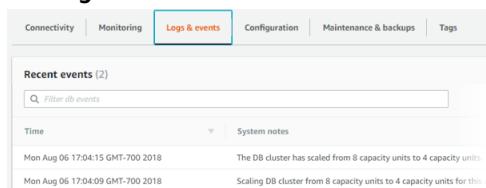

On the **Connectivity & security** tab, note the database endpoint. Use this endpoint to connect to your Aurora Serverless v1 DB cluster.

Choose the **Configuration** tab to view the capacity settings.

A *scaling event* is generated when the DB cluster scales up, scales down, pauses, or resumes. Choose the **Logs & events** tab to see recent events. The following image shows examples of these events.

## Monitoring capacity and scaling events for your Aurora Serverless v1 DB cluster

You can view your Aurora Serverless v1 DB cluster in CloudWatch to monitor the capacity allocated to the DB cluster with the `ServerlessDatabaseCapacity` metric. You can also monitor all of the standard Aurora CloudWatch metrics, such as `CPUUtilization`, `DatabaseConnections`, `Queries`, and so on.

You can have Aurora publish some or all database logs to CloudWatch. You select the logs to publish by enabling the [configuration parameters such as `general\_log` and `slow\_query\_log`](#) in the DB cluster parameter group (p. 1554) associated with the Aurora Serverless v1 cluster. Unlike provisioned clusters, Aurora Serverless v1 clusters don't require you to specify in the DB cluster settings which log types to upload to CloudWatch. Aurora Serverless v1 clusters automatically upload all the available logs. When you disable a log configuration parameter, publishing of the log to CloudWatch stops. You can also delete the logs in CloudWatch if they are no longer needed.

To get started with Amazon CloudWatch for your Aurora Serverless v1 DB cluster, see [Viewing Aurora Serverless v1 logs with Amazon CloudWatch \(p. 1557\)](#). To learn more about how to monitor Aurora DB clusters through CloudWatch, see [Monitoring log events in Amazon CloudWatch \(p. 927\)](#).

To connect to an Aurora Serverless v1 DB cluster, use the database endpoint. For more information, see [Connecting to an Amazon Aurora DB cluster \(p. 207\)](#).

**Note**

You can't connect directly to specific DB instances in your Aurora Serverless v1 DB clusters.

## Deleting an Aurora Serverless v1 DB cluster

When you create an Aurora Serverless v1 DB cluster using the AWS Management Console, the **Enable default protection** option is enabled by default unless you deselect it. That means that you can't immediately delete an Aurora Serverless v1 DB cluster that has **Deletion protection** enabled. To delete Aurora Serverless v1 DB clusters that have deletion protection by using the AWS Management Console, you first modify the cluster to remove this protection. For information about using the AWS CLI for this task, see [AWS CLI \(p. 1579\)](#).

### To disable deletion protection using the AWS Management Console

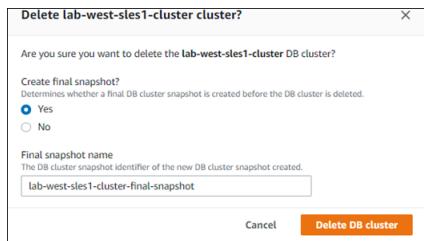

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **DB clusters**.
3. Choose your Aurora Serverless v1 DB cluster from the list.
4. Choose **Modify** to open your DB cluster's configuration. The Modify DB cluster page opens the Settings, Capacity settings, and other configuration details for your Aurora Serverless v1 DB cluster. Deletion protection is in the **Additional configuration** section.
5. Clear the **Enable deletion protection** check box in the **Additional configuration** properties card.
6. Choose **Continue**. The **Summary of modifications** appears.
7. Choose **Modify cluster** to accept the summary of modifications. You can also choose **Back** to modify your changes or **Cancel** to discard your changes.

After deletion protection is no longer active, you can delete your Aurora Serverless v1 DB cluster by using the AWS Management Console.

## Console

### To delete an Aurora Serverless v1 DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the **Resources** section, choose **DB Clusters**.
3. Choose the Aurora Serverless v1 DB cluster that you want to delete.
4. For **Actions**, choose **Delete**. You're prompted to confirm that you want to delete your Aurora Serverless v1 DB cluster.
5. We recommend that you keep the preselected options:
  - Yes for **Create final snapshot?**
  - Your Aurora Serverless v1 DB cluster name plus **-final-snapshot** for **Final snapshot name**. However, you can change the name for your final snapshot in this field.

If you choose **No** for **Create final snapshot?** you can't restore your DB cluster using snapshots or point-in-time recovery.

## 6. Choose Delete DB cluster.

Aurora Serverless v1 deletes your DB cluster. If you chose to have a final snapshot, you see your Aurora Serverless v1 DB cluster's status change to "Backing-up" before it's deleted and no longer appears in the list.

## AWS CLI

Before you begin, configure your AWS CLI with your AWS Access Key ID, AWS Secret Access Key, and the AWS Region where your Aurora Serverless v1 DB cluster is. For more information, see [Configuration basics](#) in the AWS Command Line Interface User Guide.

You can't delete an Aurora Serverless v1 DB cluster until after you first disable deletion protection for clusters configured with this option. If you try to delete a cluster that has this protection option enabled, you see the following error message.

```
An error occurred (InvalidParameterCombination) when calling the DeleteDBCluster operation: Cannot delete protected Cluster, please disable deletion protection and try again.
```

You can change your Aurora Serverless v1 DB cluster's deletion-protection setting by using the [modify-db-cluster](#) AWS CLI command as shown in the following:

```
aws rds modify-db-cluster --db-cluster-identifier your-cluster-name --no-deletion-protection
```

This command returns the revised properties for the specified DB cluster. You can now delete your Aurora Serverless v1 DB cluster.

We recommend that you always create a final snapshot whenever you delete an Aurora Serverless v1 DB cluster. The following example of using the AWS CLI [delete-db-cluster](#) shows you how. You provide the name of your DB cluster and a name for the snapshot.

For Linux, macOS, or Unix:

```
aws rds delete-db-cluster --db-cluster-identifier \
your-cluster-name --no-skip-final-snapshot \
--final-db-snapshot-identifier name-your-snapshot
```

For Windows:

```
aws rds delete-db-cluster --db-cluster-identifier ^
```

```
your-cluster-name --no-skip-final-snapshot ^
--final-db-snapshot-identifier name-your-snapshot
```

# Aurora Serverless v1 and Aurora database engine versions

Aurora Serverless v1 is available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For the current list of AWS Regions that support Aurora Serverless v1 and the specific Aurora MySQL and Aurora PostgreSQL versions available in each Region, see [Aurora Serverless v1 \(p. 32\)](#).

Aurora Serverless v1 uses its associated Aurora database engine to identify specific supported releases for each database engine supported, as follows:

- Aurora MySQL Serverless
- Aurora PostgreSQL Serverless

When minor releases of the database engines become available for Aurora Serverless v1, they are applied automatically in the various AWS Regions where Aurora Serverless v1 is available. In other words, you don't need to upgrade your Aurora Serverless v1 DB cluster to get a new minor release for your cluster's DB engine when it's available for Aurora Serverless v1.

## Aurora MySQL Serverless

If you want to use Aurora MySQL-Compatible Edition for your Aurora Serverless v1 DB cluster, you can choose between Aurora MySQL 5.6-compatible and Aurora MySQL 5.7-compatible versions. These two editions of Aurora MySQL differ significantly. We recommend that you compare their differences before creating your Aurora Serverless DB cluster so that you make the right choice for your use case. To learn about enhancements and bug fixes for Aurora MySQL Serverless 5.6 and 5.7, see [Database engine updates for Aurora Serverless clusters](#) in the *Release Notes for Aurora MySQL*.

## Aurora PostgreSQL Serverless

If you want to use Aurora PostgreSQL for your Aurora Serverless v1 DB cluster, you can choose among Aurora PostgreSQL 10-compatible and 11-compatible versions. Minor releases for Aurora PostgreSQL-Compatible Edition include only changes that are backward-compatible. Your Aurora Serverless v1 DB cluster is transparently upgraded when an Aurora PostgreSQL minor release becomes available for Aurora Serverless v1 in your AWS Region.

For example, the minor version Aurora PostgreSQL 10.18 release was transparently applied to all Aurora Serverless v1 DB clusters running the previous Aurora PostgreSQL version. For more information about the Aurora PostgreSQL version 10.18 update, see [PostgreSQL 10.18](#) in the *Release Notes for Aurora PostgreSQL*.

# Using the Data API for Aurora Serverless v1

By using the Data API for Aurora Serverless v1, you can work with a web-services interface to your Aurora Serverless v1 DB cluster. The Data API doesn't require a persistent connection to the DB cluster. Instead, it provides a secure HTTP endpoint and integration with AWS SDKs. You can use the endpoint to run SQL statements without managing connections.

All calls to the Data API are synchronous. By default, a call times out if it's not finished processing within 45 seconds. However, you can continue running a SQL statement if the call times out by using the `continueAfterTimeout` parameter. For an example, see [Running a SQL transaction \(p. 1600\)](#).

Users don't need to pass credentials with calls to the Data API, because the Data API uses database credentials stored in AWS Secrets Manager. To store credentials in Secrets Manager, users must be granted the appropriate permissions to use Secrets Manager, and also the Data API. For more information about authorizing users, see [Authorizing access to the Data API \(p. 1582\)](#).

You can also use Data API to integrate Aurora Serverless v1 with other AWS applications such as AWS Lambda, AWS AppSync, and AWS Cloud9. The API provides a more secure way to use AWS Lambda. It enables you to access your DB cluster without your needing to configure a Lambda function to access resources in a virtual private cloud (VPC). For more information, see [AWS Lambda](#), [AWS AppSync](#), and [AWS Cloud9](#).

You can enable the Data API when you create the Aurora Serverless v1 cluster. You can also modify the configuration later. For more information, see [Enabling the Data API \(p. 1584\)](#).

After you enable the Data API, you can also use the query editor for Aurora Serverless v1. For more information, see [Using the query editor for Aurora Serverless v1 \(p. 1613\)](#).

**Note**

The Data API and query editor aren't supported for Aurora Serverless v2.

**Topics**

- [Data API availability \(p. 1581\)](#)
- [Authorizing access to the Data API \(p. 1582\)](#)
- [Enabling the Data API \(p. 1584\)](#)
- [Creating an Amazon VPC endpoint for the Data API \(AWS PrivateLink\) \(p. 1586\)](#)
- [Calling the Data API \(p. 1588\)](#)
- [Using the Java client library for Data API \(p. 1602\)](#)

- [Troubleshooting Data API issues \(p. 1608\)](#)
- [Logging Data API calls with AWS CloudTrail \(p. 1610\)](#)

## Data API availability

The Data API is available only for Aurora Serverless v1 DB clusters using specific Aurora MySQL and Aurora PostgreSQL versions, and in specific AWS Regions. For more information, see [Data API for Aurora Serverless v1 \(p. 33\)](#).

If you require cryptographic modules validated by FIPS 140-2 when accessing the Data API through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-2](#).

## Authorizing access to the Data API

Users can invoke Data API operations only if they are authorized to do so. You can give a user permission to use the Data API by attaching an AWS Identity and Access Management (IAM) policy that defines their privileges. You can also attach the policy to a role if you're using IAM roles. An AWS managed policy, `AmazonRDSDataFullAccess`, includes permissions for the RDS Data API.

The `AmazonRDSDataFullAccess` policy also includes permissions for the user to get the value of a secret from AWS Secrets Manager. Users need to use Secrets Manager to store secrets that they can use in their calls to the Data API. Using secrets means that users don't need to include database credentials for the resources that they target in their calls to the Data API. The Data API transparently calls Secrets Manager, which allows (or denies) the user's request for the secret. For information about setting up secrets to use with the Data API, see [Storing database credentials in AWS Secrets Manager \(p. 1584\)](#).

The `AmazonRDSDataFullAccess` policy provides complete access (through the Data API) to resources. You can narrow the scope by defining your own policies that specify the Amazon Resource Name (ARN) of a resource.

For example, the following policy shows an example of the minimum required permissions for a user to access the Data API for the DB cluster identified by its ARN. The policy includes the needed permissions to access Secrets Manager and get authorization to the DB instance for the user.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "SecretsManagerDbCredentialsAccess",  
            "Effect": "Allow",  
            "Action": [  
                "secretsmanager:GetSecretValue"  
            ],  
            "Resource": "arn:aws:secretsmanager:*:secret:rds-db-credentials/*"  
        },  
        {  
            "Sid": "RDSDataserviceAccess",  
            "Effect": "Allow",  
            "Action": [  
                "rds-data:BatchExecuteStatement",  
                "rds-data:BeginTransaction",  
                "rds-data:CommitTransaction",  
                "rds-data:ExecuteStatement",  
                "rds-data:RollbackTransaction"  
            ],  
            "Resource": "arn:aws:rds:us-east-2:111122223333:cluster:prod"  
        }  
    ]  
}
```

We recommend that you use a specific ARN for the "Resources" element in your policy statements (as shown in the example) rather than a wildcard (\*).

## Working with tag-based authorization

The Data API and Secrets Manager both support tag-based authorization. *Tags* are key-value pairs that label a resource, such as an RDS cluster, with an additional string value, for example:

- environment:production
- environment:development

You can apply tags to your resources for cost allocation, operations support, access control, and many other reasons. (If you don't already have tags on your resources and you want to apply them, you can learn more at [Tagging Amazon RDS resources](#).) You can use the tags in your policy statements to limit access to the RDS clusters that are labeled with these tags. As an example, an Aurora DB cluster might have tags that identify its environment as either production or development.

The following example shows how you can use tags in your policy statements. This statement requires that both the cluster and the secret passed in the Data API request have an environment:production tag.

Here's how the policy gets applied: When a user makes a call using the Data API, the request is sent to the service. The Data API first verifies that the cluster ARN passed in the request is tagged with environment:production. It then calls Secrets Manager to retrieve the value of the user's secret in the request. Secrets Manager also verifies that the user's secret is tagged with environment:production. If so, Data API then uses the retrieved value for the user's DB password. Finally, if that's also correct, the Data API request is invoked successfully for the user.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SecretsManagerDbCredentialsAccess",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue"
            ],
            "Resource": "arn:aws:secretsmanager:*::secret:rds-db-credentials/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/environment": [
                        "production"
                    ]
                }
            }
        },
        {
            "Sid": "RDSDataserviceAccess",
            "Effect": "Allow",
            "Action": [
                "rds-data:)"
            ],
            "Resource": "arn:aws:rds:us-east-2:111122223333:cluster:*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/environment": [
                        "production"
                    ]
                }
            }
        }
    ]
}
```

The example shows separate actions for rds-data and secretsmanager for the Data API and Secrets Manager. However, you can combine actions and define tag conditions in many different ways to support your specific use cases. For more information, see [Using identity-based policies \(IAM policies\) for Secrets Manager](#).

In the "Condition" element of the policy, you can choose tag keys from among the following:

- `aws:TagKeys`
- `aws:ResourceTag/${TagKey}`

To learn more about resource tags and how to use `aws:TagKeys`, see [Controlling access to AWS resources using resource tags](#).

**Note**

Both the Data API and AWS Secrets Manager authorize users. If you don't have permissions for all actions defined in a policy, you get an `AccessDeniedException` error.

## Storing database credentials in AWS Secrets Manager

When you call the Data API, you can pass credentials for the Aurora Serverless v1 DB cluster by using a secret in Secrets Manager. To pass credentials in this way, you specify the name of the secret or the Amazon Resource Name (ARN) of the secret.

### To store DB cluster credentials in a secret

1. Use Secrets Manager to create a secret that contains credentials for the Aurora DB cluster.  
For instructions, see [Create a database secret](#) in the *AWS Secrets Manager User Guide*.
2. Use the Secrets Manager console to view the details for the secret you created, or run the `aws secretsmanager describe-secret` AWS CLI command.

Note the name and ARN of the secret. You can use them in calls to the Data API.

For more information about using Secrets Manager, see the [AWS Secrets Manager User Guide](#).

To understand how Amazon Aurora manages identity and access management, see [How Amazon Aurora works with IAM](#).

For more information about creating an IAM policy, see [Creating IAM Policies](#) in the *IAM User Guide*. For information about adding an IAM policy to a user, see [Adding and Removing IAM Identity Permissions](#) in the *IAM User Guide*.

## Enabling the Data API

To use the Data API, enable it for your Aurora Serverless v1 DB cluster. You can enable the Data API when you create or modify the DB cluster.

**Note**

Currently, you can't use the Data API with Aurora Serverless v2 DB instances.

### Console

You can enable the Data API by using the RDS console when you create or modify an Aurora Serverless v1 DB cluster. When you create an Aurora Serverless v1 DB cluster, you do so by enabling the Data API in the RDS console's **Connectivity** section. When you modify an Aurora Serverless v1 DB cluster, you do so by enabling the Data API in the RDS console's **Network & Security** section.

The following screenshot shows the enabled **Data API** when modifying an Aurora Serverless v1 DB cluster.

## Connectivity

**VPC security group**  
Choose a VPC security group to allow access to your database. Ensure that the security group rules allow the appropriate incoming traffic.

*Choose VPC security groups* ▾

**default X**

**Web Service Data API**

**Data API** [Info](#)

Enable the SQL HTTP endpoint, a connectionless Web Service API for running SQL queries against this database. When the SQL HTTP endpoint is enabled, you can also query your database from inside the RDS console (these features are free to use).

For instructions, see [Creating an Aurora Serverless v1 DB cluster \(p. 1559\)](#) and [Modifying an Aurora Serverless v1 DB cluster \(p. 1570\)](#).

## AWS CLI

When you create or modify an Aurora Serverless v1 DB cluster using AWS CLI commands, the Data API is enabled when you specify `--enable-http-endpoint`.

You can specify the `--enable-http-endpoint` using the following AWS CLI commands:

- [create-db-cluster](#)
- [modify-db-cluster](#)

The following example modifies `sample-cluster` to enable the Data API.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
  --db-cluster-identifier sample-cluster \
  --enable-http-endpoint
```

For Windows:

```
aws rds modify-db-cluster ^
  --db-cluster-identifier sample-cluster ^
  --enable-http-endpoint
```

## RDS API

When you create or modify an Aurora Serverless v1 DB cluster using Amazon RDS API operations, you enable the Data API by setting the `EnableHttpEndpoint` value to `true`.

You can set the `EnableHttpEndpoint` value using the following API operations:

- [CreateDBCluster](#)
- [ModifyDBCluster](#)

# Creating an Amazon VPC endpoint for the Data API (AWS PrivateLink)

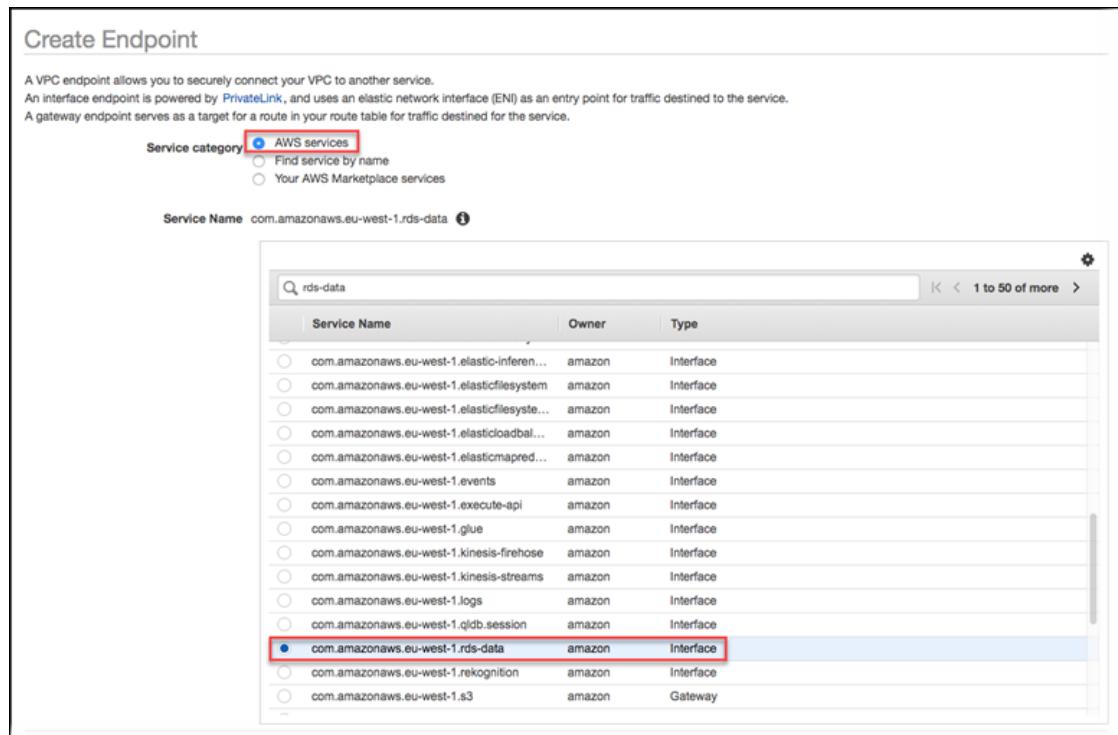

Amazon VPC enables you to launch AWS resources, such as Aurora DB clusters and applications, into a virtual private cloud (VPC). AWS PrivateLink provides private connectivity between VPCs and AWS services with high security on the Amazon network. Using AWS PrivateLink, you can create Amazon VPC endpoints, which enable you to connect to services across different accounts and VPCs based on Amazon VPC. For more information about AWS PrivateLink, see [VPC Endpoint Services \(AWS PrivateLink\)](#) in the [Amazon Virtual Private Cloud User Guide](#).

You can call the Data API with Amazon VPC endpoints. Using an Amazon VPC endpoint keeps traffic between applications in your Amazon VPC and the Data API in the AWS network, without using public IP addresses. Amazon VPC endpoints can help you meet compliance and regulatory requirements related to limiting public internet connectivity. For example, if you use an Amazon VPC endpoint, you can keep traffic between an application running on an Amazon EC2 instance and the Data API in the VPCs that contain them.

After you create the Amazon VPC endpoint, you can start using it without making any code or configuration changes in your application.

## To create an Amazon VPC endpoint for the Data API

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Choose **Endpoints**, and then choose **Create Endpoint**.
3. On the **Create Endpoint** page, for **Service category**, choose **AWS services**. For **Service Name**, choose **rds-data**.

4. For **VPC**, choose the VPC to create the endpoint in.

Choose the VPC that contains the application that makes Data API calls.

- For **Subnets**, choose the subnet for each Availability Zone (AZ) used by the AWS service that is running your application.

Availability Zone	Subnet ID
<input checked="" type="checkbox"/> eu-west-1a (euw1-az2)	subnet-2c8ee364
<input checked="" type="checkbox"/> eu-west-1b (euw1-az3)	subnet-cefa2594
<input checked="" type="checkbox"/> eu-west-1c (euw1-az1)	subnet-20c45946

To create an Amazon VPC endpoint, specify the private IP address range in which the endpoint will be accessible. To do this, choose the subnet for each Availability Zone. Doing so restricts the VPC endpoint to the private IP address range specific to each Availability Zone and also creates an Amazon VPC endpoint in each Availability Zone.

- For **Enable DNS name**, select **Enable for this endpoint**.

Enable DNS name  Enable for this endpoint

To use private DNS names, ensure that the attributes 'Enable DNS hostnames' and 'Enable DNS Support' are set to 'true' for your VPC (vpc-c20d2da4). [Learn more.](#)

Private DNS resolves the standard Data API DNS hostname (`https://rds-data.region.amazonaws.com`) to the private IP addresses associated with the DNS hostname specific to your Amazon VPC endpoint. As a result, you can access the Data API VPC endpoint using the AWS CLI or AWS SDKs without making any code or configuration changes to update the Data API endpoint URL.

- For **Security group**, choose a security group to associate with the Amazon VPC endpoint.

Choose the security group that allows access to the AWS service that is running your application. For example, if an Amazon EC2 instance is running your application, choose the security group that allows access to the Amazon EC2 instance. The security group enables you to control the traffic to the Amazon VPC endpoint from resources in your VPC.

- For **Policy**, choose **Full Access** to allow anyone inside the Amazon VPC to access the Data API through this endpoint. Or choose **Custom** to specify a policy that limits access.

If you choose **Custom**, enter the policy in the policy creation tool.

- Choose **Create endpoint**.

After the endpoint is created, choose the link in the AWS Management Console to view the endpoint details.

Endpoints > Create Endpoint

## Create Endpoint

The following VPC Endpoint was created:

VPC Endpoint ID vpce-0...

The endpoint **Details** tab shows the DNS hostnames that were generated while creating the Amazon VPC endpoint.

Endpoint: vpce-04ec15ecbab57bf10							
		Details	Subnets	Security Groups	Policy	Notifications	Tags
Endpoint ID	vpce-04ec15ecbab57bf10	VPC ID	vpc-c20d2da4				
Status	available	Status message					
Creation time	January 31, 2020 at 7:02:32 PM UTC-8	Service name	com.amazonaws.eu-west-1.rds-data				
Endpoint type	Interface	DNS names	vpce-[REDACTED].rds-data.eu-west-1.vpce.amazonaws.com ([REDACTED]) vpce-[REDACTED]-eu-west-1b.rds-data.eu-west-1.vpce.amazonaws.com ([REDACTED]) vpce-[REDACTED]-eu-west-1c.rds-data.eu-west-1.vpce.amazonaws.com ([REDACTED]) vpce-[REDACTED]-eu-west-1a.rds-data.eu-west-1.vpce.amazonaws.com ([REDACTED]) rds-data.eu-west-1.amazonaws.com ([REDACTED])				
Private DNS names enabled	true	Private DNS name	rds-data.eu-west-1.amazonaws.com				

You can use the standard endpoint (`rds-data.region.amazonaws.com`) or one of the VPC-specific endpoints to call the Data API within the Amazon VPC. The standard Data API endpoint automatically routes to the Amazon VPC endpoint. This routing occurs because the Private DNS hostname was enabled when the Amazon VPC endpoint was created.

When you use an Amazon VPC endpoint in a Data API call, all traffic between your application and the Data API remains in the Amazon VPCs that contain them. You can use an Amazon VPC endpoint for any type of Data API call. For information about calling the Data API, see [Calling the Data API \(p. 1588\)](#).

## Calling the Data API

With the Data API enabled on your Aurora Serverless v1 DB cluster, you can run SQL statements on the Aurora DB cluster by using the Data API or the AWS CLI. The Data API supports the programming languages supported by the AWS SDKs. For more information, see [Tools to build on AWS](#).

**Note**

Currently, the Data API doesn't support arrays of Universal Unique Identifiers (UUIDs).

The Data API provides the following operations to perform SQL statements.

Data API operation	AWS CLI command	Description
<code>ExecuteStatement</code>	<code>rds-data execute-statement</code>	Runs a SQL statement on a database.
<code>BatchExecuteStatement</code>	<code>rds-data batch-execute-statement</code>	Runs a batch SQL statement over an array of data for bulk update and insert operations. You can run a data manipulation language (DML) statement with an array of parameter sets. A batch SQL statement can provide a significant performance improvement over individual insert and update statements.

You can use either operation to run individual SQL statements or to run transactions. For transactions, the Data API provides the following operations.

Data API operation	AWS CLI command	Description
BeginTransaction	<code>rds-data begin-transaction</code>	Starts a SQL transaction.
CommitTransaction	<code>rds-data commit-transaction</code>	Ends a SQL transaction and commits the changes.
RollbackTransaction	<code>rds-data rollback-transaction</code>	Performs a rollback of a transaction.

The operations for performing SQL statements and supporting transactions have the following common Data API parameters and AWS CLI options. Some operations support other parameters or options.

Data API operation parameter	AWS CLI command option	Required	Description
<code>resourceArn</code>	<code>--resource-arn</code>	Yes	The Amazon Resource Name (ARN) of the Aurora Serverless v1 DB cluster.
<code>secretArn</code>	<code>--secret-arn</code>	Yes	The name or ARN of the secret that enables access to the DB cluster.

You can use parameters in Data API calls to `ExecuteStatement` and `BatchExecuteStatement`, and when you run the AWS CLI commands `execute-statement` and `batch-execute-statement`. To use a parameter, you specify a name-value pair in the `SqlParameter` data type. You specify the value with the `Field` data type. The following table maps Java Database Connectivity (JDBC) data types to the data types that you specify in Data API calls.

JDBC data type	Data API data type
<code>INTEGER, TINYINT, SMALLINT, BIGINT</code>	<code>LONG (or STRING)</code>
<code>FLOAT, REAL, DOUBLE</code>	<code>DOUBLE</code>
<code>DECIMAL</code>	<code>STRING</code>
<code>BOOLEAN, BIT</code>	<code>BOOLEAN</code>
<code>BLOB, BINARY, LONGVARBINARY, VARBINARY</code>	<code>BLOB</code>
<code>CLOB</code>	<code>STRING</code>
Other types (including types related to date and time)	<code>STRING</code>

#### Note

You can specify the `LONG` or `STRING` data type in your Data API call for `LONG` values returned by the database. We recommend that you do so to avoid losing precision for extremely large numbers, which can happen when you work with JavaScript.

Certain types, such as `DECIMAL` and `TIME`, require a hint so that the Data API passes `String` values to the database as the correct type. To use a hint, include values for `typeHint` in the `SqlParameter` data type. The possible values for `typeHint` are the following:

- `DATE` – The corresponding `String` parameter value is sent as an object of `DATE` type to the database. The accepted format is `YYYY-MM-DD`.
- `DECIMAL` – The corresponding `String` parameter value is sent as an object of `DECIMAL` type to the database.
- `JSON` – The corresponding `String` parameter value is sent as an object of `JSON` type to the database.
- `TIME` – The corresponding `String` parameter value is sent as an object of `TIME` type to the database. The accepted format is `HH:MM:SS[ .FFF ]`.
- `TIMESTAMP` – The corresponding `String` parameter value is sent as an object of `TIMESTAMP` type to the database. The accepted format is `YYYY-MM-DD HH:MM:SS[ .FFF ]`.
- `UUID` – The corresponding `String` parameter value is sent as an object of `UUID` type to the database.

**Note**

For Amazon Aurora PostgreSQL, the Data API always returns the Aurora PostgreSQL data type `TIMESTAMPTZ` in UTC time zone.

## Calling the Data API with the AWS CLI

You can call the Data API using the AWS CLI.

The following examples use the AWS CLI for the Data API. For more information, see [AWS CLI reference for the Data API](#).

In each example, replace the Amazon Resource Name (ARN) for the DB cluster with the ARN for your Aurora Serverless v1 DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

**Note**

The AWS CLI can format responses in JSON.

### Topics

- [Starting a SQL transaction \(p. 1590\)](#)
- [Running a SQL statement \(p. 1591\)](#)
- [Running a batch SQL statement over an array of data \(p. 1594\)](#)
- [Committing a SQL transaction \(p. 1595\)](#)
- [Rolling back a SQL transaction \(p. 1596\)](#)

## Starting a SQL transaction

You can start a SQL transaction using the `aws rds-data begin-transaction` CLI command. The call returns a transaction identifier.

**Important**

A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.

Data definition language (DDL) statements inside a transaction cause an implicit commit. We recommend that you run each DDL statement in a separate `execute-statement` command with the `--continue-after-timeout` option.

In addition to the common options, specify the `--database` option, which provides the name of the database.

For example, the following CLI command starts a SQL transaction.

For Linux, macOS, or Unix:

```
aws rds-data begin-transaction --resource-arn "arn:aws:rds:us-  
east-1:123456789012:cluster:mydbcluster" \  
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-  
east-1:123456789012:secret:mysecret"
```

For Windows:

```
aws rds-data begin-transaction --resource-arn "arn:aws:rds:us-  
east-1:123456789012:cluster:mydbcluster" ^  
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-  
east-1:123456789012:secret:mysecret"
```

The following is an example of the response.

```
{  
    "transactionId": "ABC1234567890xyz"  
}
```

## Running a SQL statement

You can run a SQL statement using the `aws rds-data execute-statement` CLI command.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction using the `aws rds-data commit-transaction` CLI command.

### Important

If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql` (required) – A SQL statement to run on the DB cluster.
- `--transaction-id` (optional) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.
- `--parameters` (optional) – The parameters for the SQL statement.
- `--include-result-metadata` | `--no-include-result-metadata` (optional) – A value that indicates whether to include metadata in the results. The default is `--no-include-result-metadata`.
- `--database` (optional) – The name of the database.
- `--continue-after-timeout` | `--no-continue-after-timeout` (optional) – A value that indicates whether to continue running the statement after the call times out. The default is `--no-continue-after-timeout`.

For data definition language (DDL) statements, we recommend continuing to run the statement after the call times out to avoid errors and the possibility of corrupted data structures.

- `--format-records-as "JSON" | "NONE"` – An optional value that specifies whether to format the result set as a JSON string. The default is "NONE". For usage information about processing JSON result sets, see [Processing query results in JSON format \(p. 1603\)](#).

The DB cluster returns a response for the call.

**Note**

The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.

The maximum number of requests per second is 1,000.

For example, the following CLI command runs a single SQL statement and omits the metadata in the results (the default).

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--sql "select * from mytable"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "select * from mytable"
```

The following is an example of the response.

```
{
  "numberOfRecordsUpdated": 0,
  "records": [
    [
      {
        "longValue": 1
      },
      {
        "stringValue": "ValueOne"
      }
    ],
    [
      {
        "longValue": 2
      },
      {
        "stringValue": "ValueTwo"
      }
    ],
    [
      {
        "longValue": 3
      },
      {
        "stringValue": "ValueThree"
      }
    ]
  ]
}
```

The following CLI command runs a single SQL statement in a transaction by specifying the `--transaction-id` option.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--sql "update mytable set quantity=5 where id=201" --transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "update mytable set quantity=5 where id=201" --transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{  
    "numberOfRecordsUpdated": 1  
}
```

The following CLI command runs a single SQL statement with parameters.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--sql "insert into mytable values (:id, :val)" --parameters "[{\\"name\\": \\"id\\", \\"value\\": \\"1\"}, {\\"name\\": \\"val\\", \\"value\\": {\\"stringValue\\": \\"value1\\\"}}]"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "insert into mytable values (:id, :val)" --parameters "[{\\"name\\": \\"id\\", \\"value\\": \\"1\"}, {\\"name\\": \\"val\\", \\"value\\": {\\"stringValue\\": \\"value1\\\"}}]"
```

The following is an example of the response.

```
{  
    "numberOfRecordsUpdated": 1  
}
```

The following CLI command runs a data definition language (DDL) SQL statement. The DDL statement renames column job to column role.

**Important**

For DDL statements, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call times out, specify the `--continue-after-timeout` option.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
```

```
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--sql "alter table mytable change column job role varchar(100)" --continue-after-timeout
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "alter table mytable change column job role varchar(100)" --continue-after-timeout
```

The following is an example of the response.

```
{
  "generatedFields": [],
  "numberOfRecordsUpdated": 0
}
```

**Note**

The `generatedFields` data isn't supported by Aurora PostgreSQL. To get the values of generated fields, use the `RETURNING` clause. For more information, see [Returning data from modified rows](#) in the PostgreSQL documentation.

## Running a batch SQL statement over an array of data

You can run a batch SQL statement over an array of data by using the `aws rds-data batch-execute-statement` CLI command. You can use this command to perform a bulk import or update operation.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction by using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction by using the `aws rds-data commit-transaction` CLI command.

**Important**

If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql` (required) – A SQL statement to run on the DB cluster.

**Tip**

For MySQL-compatible statements, don't include a semicolon at the end of the `--sql` parameter. A trailing semicolon might cause a syntax error.

- `--transaction-id` (optional) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.
- `--parameter-set` (optional) – The parameter sets for the batch operation.
- `--database` (optional) – The name of the database.

The DB cluster returns a response to the call.

**Note**

There isn't a fixed upper limit on the number of parameter sets. However, the maximum size of the HTTP request submitted through the Data API is 4 MiB. If the request exceeds this limit, the Data API returns an error and doesn't process the request. This 4 MiB limit includes the size of the HTTP headers and the JSON notation in the request. Thus, the number of parameter sets

that you can include depends on a combination of factors, such as the size of the SQL statement and the size of each parameter set.

The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.

The maximum number of requests per second is 1,000.

For example, the following CLI command runs a batch SQL statement over an array of data with a parameter set.

For Linux, macOS, or Unix:

```
aws rds-data batch-execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--sql "insert into mytable values (:id, :val)" \
--parameter-sets "[[{"name": "\$id", "value": {"longValue": 1}}, {"name": "\$val", "value": {"stringValue": "ValueOne"}}, {"name": "\$id", "value": {"longValue": 2}}, {"name": "\$val", "value": {"stringValue": "ValueTwo"}}, {"name": "\$id", "value": {"longValue": 3}}, {"name": "\$val", "value": {"stringValue": "ValueThree"}}]]"
```

For Windows:

```
aws rds-data batch-execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "insert into mytable values (:id, :val)" ^
--parameter-sets "[[{"name": "\$id", "value": {"longValue": 1}}, {"name": "\$val", "value": {"stringValue": "ValueOne"}}, {"name": "\$id", "value": {"longValue": 2}}, {"name": "\$val", "value": {"stringValue": "ValueTwo"}}, {"name": "\$id", "value": {"longValue": 3}}, {"name": "\$val", "value": {"stringValue": "ValueThree"}}]]"
```

#### Note

Don't include line breaks in the `--parameter-sets` option.

## Committing a SQL transaction

Using the `aws rds-data commit-transaction` CLI command, you can end a SQL transaction that you started with `aws rds-data begin-transaction` and commit the changes.

In addition to the common options, specify the following option:

- `--transaction-id` (required) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to end and commit.

For example, the following CLI command ends a SQL transaction and commits the changes.

For Linux, macOS, or Unix:

```
aws rds-data commit-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data commit-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{  
    "transactionStatus": "Transaction Committed"  
}
```

## Rolling back a SQL transaction

Using the `aws rds-data rollback-transaction` CLI command, you can roll back a SQL transaction that you started with `aws rds-data begin-transaction`. Rolling back a transaction cancels its changes.

### Important

If the transaction ID has expired, the transaction was rolled back automatically. In this case, an `aws rds-data rollback-transaction` command that specifies the expired transaction ID returns an error.

In addition to the common options, specify the following option:

- `--transaction-id` (required) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to roll back.

For example, the following AWS CLI command rolls back a SQL transaction.

For Linux, macOS, or Unix:

```
aws rds-data rollback-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data rollback-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{  
    "transactionStatus": "Rollback Complete"  
}
```

## Calling the Data API from a Python application

You can call the Data API from a Python application.

The following examples use the AWS SDK for Python (Boto). For more information about Boto, see the [AWS SDK for Python \(Boto 3\) documentation](#).

In each example, replace the DB cluster's Amazon Resource Name (ARN) with the ARN for your Aurora Serverless v1 DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

### Topics

- [Running a SQL query \(p. 1597\)](#)
- [Running a DML SQL statement \(p. 1598\)](#)
- [Running a SQL transaction \(p. 1598\)](#)

## Running a SQL query

You can run a `SELECT` statement and fetch the results with a Python application.

The following example runs a SQL query.

```
import boto3

rdsData = boto3.client('rds-data')

cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'

response1 = rdsData.execute_statement(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    database = 'mydb',
    sql = 'select * from employees limit 3')

print (response1['records'])
[
    [
        {
            'longValue': 1
        },
        {
            'stringValue': 'ROSALEZ'
        },
        {
            'stringValue': 'ALEJANDRO'
        },
        {
            'stringValue': '2016-02-15 04:34:33.0'
        }
    ],
    [
        {
            'longValue': 1
        },
        {
            'stringValue': 'DOE'
        },
        {
            'stringValue': 'JANE'
        },
        {
            'stringValue': '2014-05-09 04:34:33.0'
        }
    ],
    [
        {
            'longValue': 1
        },
        {
            'stringValue': 'FERNANDEZ'
        },
        {
            'stringValue': 'SARAH'
        },
        {
            'stringValue': '2016-02-15 04:34:33.0'
        }
    ]
]
```

```
{  
    'stringValue': 'STILES'  
},  
{  
    'stringValue': 'JOHN'  
},  
{  
    'stringValue': '2017-09-20 04:34:33.0'  
}  
]  
]
```

## Running a DML SQL statement

You can run a data manipulation language (DML) statement to insert, update, or delete data in your database. You can also use parameters in DML statements.

**Important**

If a call isn't part of a transaction because it doesn't include the `transactionID` parameter, changes that result from the call are committed automatically.

The following example runs an insert SQL statement and uses parameters.

```
import boto3  
  
cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'  
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'  
  
rdsData = boto3.client('rds-data')  
  
param1 = {'name':'firstname', 'value':{'stringValue': 'JACKSON'}}  
param2 = {'name':'lastname', 'value':{'stringValue': 'MATEO'}}  
paramSet = [param1, param2]  
  
response2 = rdsData.execute_statement(resourceArn=cluster_arn,  
                                       secretArn=secret_arn,  
                                       database='mydb',  
                                       sql='insert into employees(first_name, last_name)  
VALUES(:firstname, :lastname)',  
                                       parameters = paramSet)  
  
print (response2["numberOfRecordsUpdated"])
```

## Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Python application.

**Important**

A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.

If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction that inserts a row in a table.

```
import boto3  
  
rdsData = boto3.client('rds-data')  
  
cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'
```

```
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'

tr = rdsData.begin_transaction(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    database = 'mydb')

response3 = rdsData.execute_statement(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    database = 'mydb',
    sql = 'insert into employees(first_name, last_name) values('XIULAN', 'WANG')',
    transactionId = tr['transactionId'])

cr = rdsData.commit_transaction(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    transactionId = tr['transactionId'])

cr['transactionStatus']
'Transaction Committed'

response3['numberOfRecordsUpdated']
1
```

#### Note

If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call times out, set the `continueAfterTimeout` parameter to `true`.

## Calling the Data API from a Java application

You can call the Data API from a Java application.

The following examples use the AWS SDK for Java. For more information, see the [AWS SDK for Java Developer Guide](#).

In each example, replace the DB cluster's Amazon Resource Name (ARN) with the ARN for your Aurora Serverless v1 DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

- [Running a batch SQL operation \(p. 1601\)](#)

## Running a SQL query

You can run a `SELECT` statement and fetch the results with a Java application.

The following example runs a SQL query.

```
package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;
import com.amazonaws.services.rdsdata.model.ExecuteStatementResult;
import com.amazonaws.services.rdsdata.model.Field;
```

```

import java.util.List;

public class FetchResultsExample {
    public static final String RESOURCE_ARN = "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster";
    public static final String SECRET_ARN = "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret";

    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();

        ExecuteStatementRequest request = new ExecuteStatementRequest()
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withDatabase("mydb")
            .withSql("select * from mytable");

        ExecuteStatementResult result = rdsData.executeStatement(request);

        for (List<Field> fields: result.getRecords()) {
            String stringValue = fields.get(0).getStringValue();
            long numberValue = fields.get(1).getLongValue();

            System.out.println(String.format("Fetched row: string = %s, number = %d",
                stringValue, numberValue));
        }
    }
}

```

## Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Java application.

### Important

A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.

If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction.

```

package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.BeginTransactionRequest;
import com.amazonaws.services.rdsdata.model.BeginTransactionResult;
import com.amazonaws.services.rdsdata.model.CommitTransactionRequest;
import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;

public class TransactionExample {
    public static final String RESOURCE_ARN = "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster";
    public static final String SECRET_ARN = "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret";

    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();

        BeginTransactionRequest beginTransactionRequest = new BeginTransactionRequest()
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)

```

```

        .withDatabase("mydb");
        BeginTransactionResult beginTransactionResult =
rdsData.beginTransactionbeginTransactionRequest();
        String transactionId = beginTransactionResult.getTransactionId();

        ExecuteStatementRequest executeStatementRequest = new ExecuteStatementRequest()
            .withTransactionId(transactionId)
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withSql("INSERT INTO test_table VALUES ('hello world!')");
rdsData.executeStatement(executeStatementRequest);

        CommitTransactionRequest commitTransactionRequest = new CommitTransactionRequest()
            .withTransactionId(transactionId)
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN);
rdsData.commitTransaction(commitTransactionRequest);
    }
}

```

#### **Note**

If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call times out, set the `continueAfterTimeout` parameter to `true`.

## Running a batch SQL operation

You can run bulk insert and update operations over an array of data with a Java application. You can run a DML statement with array of parameter sets.

#### **Important**

If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a batch insert operation.

```

package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.BatchExecuteStatementRequest;
import com.amazonaws.services.rdsdata.model.Field;
import com.amazonaws.services.rdsdata.model.SqlParameter;

import java.util.Arrays;

public class BatchExecuteExample {
    public static final String RESOURCE_ARN = "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster";
    public static final String SECRET_ARN = "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret";

    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();

        BatchExecuteStatementRequest request = new BatchExecuteStatementRequest()
            .withDatabase("test")
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withSql("INSERT INTO test_table2 VALUES (:string, :number)")
            .withParameterSets(Arrays.asList(
                Arrays.asList(

```

```
        new SqlParameter().withName("string").withValue(new
Field().withStringValue("Hello")),
        new SqlParameter().withName("number").withValue(new
Field().withLongValue(1L))
),
Arrays.asList(
        new SqlParameter().withName("string").withValue(new
Field().withStringValue("World")),
        new SqlParameter().withName("number").withValue(new
Field().withLongValue(2L))
)
));

rdsData.batchExecuteStatement(request);
}
}
```

## Using the Java client library for Data API

You can download and use a Java client library for the Data API. This Java client library provides an alternative way to use the Data API. Using this library, you can map your client-side classes to requests and responses of the Data API. This mapping support can ease integration with some specific Java types, such as Date, Time, and BigDecimal.

### Downloading the Java client library for Data API

The Data API Java client library is open source in GitHub at the following location:

<https://github.com/awslabs/rds-data-api-client-library-java>

You can build the library manually from the source files, but the best practice is to consume the library using Apache Maven dependency management. Add the following dependency to your Maven POM file.

For version 2.x, which is compatible with AWS SDK 2.x, use the following:

```
<dependency>
<groupId>software.amazon.rdsdata</groupId>
<artifactId>rds-data-api-client-library-java</artifactId>
<version>2.0.0</version>
</dependency>
```

For version 1.x, which is compatible with AWS SDK 1.x, use the following:

```
<dependency>
<groupId>software.amazon.rdsdata</groupId>
<artifactId>rds-data-api-client-library-java</artifactId>
<version>1.0.8</version>
</dependency>
```

## Java client library examples

Following, you can find some common examples of using the Data API Java client library. These examples assume that you have a table accounts with two columns: accountId and name. You also have the following data transfer object (DTO).

```
public class Account {
    int accountId;
```

```

    String name;
    // getters and setters omitted
}

```

The client library enables you to pass DTOs as input parameters. The following example shows how customer DTOs are mapped to input parameters sets.

```

var account1 = new Account(1, "John");
var account2 = new Account(2, "Mary");
client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)")
    .withParamSets(account1, account2)
    .execute();

```

In some cases, it's easier to work with simple values as input parameters. You can do so with the following syntax.

```

client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)")
    .withParameter("accountId", 3)
    .withParameter("name", "Zhang")
    .execute();

```

The following is another example that works with simple values as input parameters.

```

client.forSql("INSERT INTO accounts(accountId, name) VALUES(?, ?)", 4, "Carlos")
    .execute();

```

The client library provides automatic mapping to DTOs when a result is returned. The following examples show how the result is mapped to your DTOs.

```

List<Account> result = client.forSql("SELECT * FROM accounts")
    .execute()
    .mapToList(Account.class);

Account result = client.forSql("SELECT * FROM accounts WHERE account_id = 1")
    .execute()
    .mapToSingle(Account.class);

```

In many cases, the database result set contains only a single value. In order to simplify retrieving such results, the client library offers the following API:

```

int numberOfAccounts = client.forSql("SELECT COUNT(*) FROM accounts")
    .execute()
    .singleValue(Integer.class);

```

#### Note

The `mapToList` function converts a SQL result set into a user-defined object list. We don't support using the `.withFormatRecordsAs(RecordsFormatType.JSON)` statement in an `ExecuteStatement` call for the Java client library, because it serves the same purpose. For more information, see [Processing query results in JSON format \(p. 1603\)](#).

## Processing query results in JSON format

When you call the `ExecuteStatement` operation, you can choose to have the query results returned as a string in JSON format. That way, you can use your programming language's JSON parsing capabilities

to interpret and reformat the result set. Doing so can help to avoid writing extra code to loop through the result set and interpret each column value.

To request the result set in JSON format, you pass the optional `formatRecordsAs` parameter with a value of `JSON`. The JSON-formatted result set is returned in the `formattedRecords` field of the `ExecuteStatementResponse` structure.

The `BatchExecuteStatement` action doesn't return a result set. Thus, the JSON option doesn't apply to that action.

To customize the keys in the JSON hash structure, define column aliases in the result set. You can do so by using the `AS` clause in the column list of your SQL query.

You might use the JSON capability to make the result set easier to read and map its contents to language-specific frameworks. Because the volume of the ASCII-encoded result set is larger than the default representation, you might choose the default representation for queries that return large numbers of rows or large column values that consume more memory than is available to your application.

#### Topics

- [Retrieving query results in JSON format \(p. 1604\)](#)
- [Data Type Mapping \(p. 1604\)](#)
- [Troubleshooting \(p. 1605\)](#)
- [Examples \(p. 1605\)](#)

## Retrieving query results in JSON format

To receive the the result set as a JSON string, include

`.withFormatRecordsAs(RecordsFormatType.JSON)` in the `ExecuteStatement` call. The return value comes back as a JSON string in the `formattedRecords` field. In this case, the `columnMetadata` is `null`. The column labels are the keys of the object that represents each row. These column names are repeated for each row in the result set. The column values are quoted strings, numeric values, or special values representing `true`, `false`, or `null`. Column metadata such as length constraints and the precise type for numbers and strings isn't preserved in the JSON response.

If you omit the `.withFormatRecordsAs()` call or specify a parameter of `NONE`, the result set is returned in binary format using the `Records` and `columnMetadata` fields.

## Data Type Mapping

The SQL values in the result set are mapped to a smaller set of JSON types. The values are represented in JSON as strings, numbers, and some special constants such as `true`, `false`, and `null`. You can convert these values into variables in your application, using strong or weak typing as appropriate for your programming language.

JDBC data type	JSON data type
<code>INTEGER</code> , <code>TINYINT</code> , <code>SMALLINT</code> , <code>BIGINT</code>	Number by default. String if the <code>LongReturnType</code> option is set to <code>STRING</code> .
<code>FLOAT</code> , <code>REAL</code> , <code>DOUBLE</code>	Number
<code>DECIMAL</code>	String by default. Number if the <code>DecimalReturnType</code> option is set to <code>DOUBLE_OR_LONG</code> .

JDBC data type	JSON data type
STRING	String
BOOLEAN, BIT	Boolean
BLOB, BINARY, VARBINARY, LONGVARBINARY	String in base64 encoding.
CLOB	String
ARRAY	Array
NULL	null
Other types (including types related to date and time)	String

## Troubleshooting

The JSON response is limited to 10 megabytes. If the response is larger than this limit, your program receives a `BadRequestException` error. In this case, you can resolve the error using one of the following techniques:

- Reduce the number of rows in the result set. To do so, add a `LIMIT` clause. You might split a large result set into multiple smaller ones by submitting several queries with `LIMIT` and `OFFSET` clauses. If the result set includes rows that are filtered out by application logic, you can remove those rows from the result set by adding more conditions in the `WHERE` clause.
- Reduce the number of columns in the result set. To do so, remove items from the select list of the query.
- Shorten the column labels by using column aliases in the query. Each column name is repeated in the JSON string for each row in the result set. Thus, a query result with long column names and many rows could exceed the size limit. In particular, use column aliases for complicated expressions to avoid having the entire expression repeated in the JSON string.
- Although with SQL you can use column aliases to produce a result set having more than one column with the same name, duplicate key names aren't allowed in JSON. The RDS Data API returns an error if you request the result set in JSON format and more than one column has the same name. Thus, make sure that all the column labels have unique names.

## Examples

The following Java examples show how to call `ExecuteStatement` with the response as a JSON-formatted string, then interpret the result set. Substitute the appropriate values for the `databaseName`, `secretStoreArn`, and `clusterArn` parameters.

The following Java example demonstrates a query that returns a decimal numeric value in the result set. The `assertThat` calls test that the fields of the response have the expected properties based on the rules for JSON result sets.

This example works with the following schema and sample data:

```
create table test_simplified_json (a float);
insert into test_simplified_json values(10.0);

public void JSON_result_set_demo() {
```

```

var sql = "select * from test_simplified_json";
var request = new ExecuteStatementRequest()
    .withDatabase(databaseName)
    .withSecretArn(secretStoreArn)
    .withResourceArn(clusterArn)
    .withSql(sql)
    .withFormatRecordsAs(RecordsFormatType.JSON);
var result = rdsdataClient.executeStatement(request);
}

```

The value of the `formattedRecords` field from the preceding program is:

```
[{"a":10.0}]
```

The `Records` and `ColumnMetadata` fields in the response are both null, due to the presence of the JSON result set.

The following Java example demonstrates a query that returns an integer numeric value in the result set. The example calls `getFormattedRecords` to return only the JSON-formatted string and ignore the other response fields that are blank or null. The example deserializes the result into a structure representing a list of records. Each record has fields whose names correspond to the column aliases from the result set. This technique simplifies the code that parses the result set. Your application doesn't have to loop through the rows and columns of the result set and convert each value to the appropriate type.

This example works with the following schema and sample data:

```

create table test_simplified_json (a int);
insert into test_simplified_json values(17);

```

```

public void JSON_deserialization_demo() {
    var sql = "select * from test_simplified_json";
    var request = new ExecuteStatementRequest()
        .withDatabase(databaseName)
        .withSecretArn(secretStoreArn)
        .withResourceArn(clusterArn)
        .withSql(sql)
        .withFormatRecordsAs(RecordsFormatType.JSON);
    var result = rdsdataClient.executeStatement(request)
        .getFormattedRecords();

    /* Turn the result set into a Java object, a list of records.
     * Each record has a field 'a' corresponding to the column
     * labelled 'a' in the result set. */
    private static class Record { public int a; }
    var recordsList = new ObjectMapper().readValue(
        response, new TypeReference<List<Record>>() {
    });
}

```

The value of the `formattedRecords` field from the preceding program is:

```
[{"a":17}]
```

To retrieve the `a` column of result row 0, the application would refer to `recordsList.get(0).a`.

In contrast, the following Java example shows the kind of code that's required to construct a data structure holding the result set when you don't use the JSON format. In this case, each row of the result set contains fields with information about a single user. Building a data structure to represent the result set requires looping through the rows. For each row, the code retrieves the value of each field, performs an appropriate type conversion, and assigns the result to the corresponding field in the

object representing the row. Then the code adds the object representing each user to the data structure representing the entire result set. If the query was changed to reorder, add, or remove fields in the result set, the application code would have to change also.

```
/* Verbose result-parsing code that doesn't use the JSON result set format */
for (var row: response.getRecords()) {
    var user = User.builder()
        .userId(row.get(0).getLongValue())
        .firstName(row.get(1).getStringValue())
        .lastName(row.get(2).getStringValue())
        .dob(Instant.parse(row.get(3).getStringValue()))
        .build();
    result.add(user);
}
```

The following sample values show the values of the `formattedRecords` field for result sets with different numbers of columns, column aliases, and column data types.

If the result set includes multiple rows, each row is represented as an object that is an array element. Each column in the result set becomes a key in the object. The keys are repeated for each row in the result set. Thus, for result sets consisting of many rows and columns, you might need to define short column aliases to avoid exceeding the length limit for the entire response.

This example works with the following schema and sample data:

```
create table sample_names (id int, name varchar(128));
insert into sample_names values (0, "Jane"), (1, "Mohan"), (2, "Maria"), (3, "Bruce"), (4, "Jasmine");
```

```
[{"id":0,"name":"Jane"}, {"id":1,"name":"Mohan"}, {"id":2,"name":"Maria"}, {"id":3,"name":"Bruce"}, {"id":4,"name":"Jasmine"}]
```

If a column in the result set is defined as an expression, the text of the expression becomes the JSON key. Thus, it's typically convenient to define a descriptive column alias for each expression in the select list of the query. For example, the following query includes expressions such as function calls and arithmetic operations in its select list.

```
select count(*), max(id), 4+7 from sample_names;
```

Those expressions are passed through to the JSON result set as keys.

```
[{"count(*)":5, "max(id)":4, "4+7":11}]
```

Adding `AS` columns with descriptive labels makes the keys simpler to interpret in the JSON result set.

```
select count(*) as rows, max(id) as largest_id, 4+7 as addition_result from sample_names;
```

With the revised SQL query, the column labels defined by the `AS` clauses are used as the key names.

```
[{"rows":5, "largest_id":4, "addition_result":11}]
```

The value for each key-value pair in the JSON string can be a quoted string. The string might contain unicode characters. If the string contains escape sequences or the `"` or `\` characters, those characters are preceded by backslash escape characters. The following examples of JSON strings demonstrate these possibilities. For example, the `string_with_escape_sequences` result contains the special characters backspace, newline, carriage return, tab, form feed, and `\``.

```
[{"quoted_string":"hello"}]  
[{"unicode_string":="#">  
[{"string_with_escape_sequences":"\b \n \r \t \f \\ ''"}]
```

The value for each key-value pair in the JSON string can also represent a number. The number might be an integer, a floating-point value, a negative value, or a value represented as exponential notation. The following examples of JSON strings demonstrate these possibilities.

```
[{"integer_value":17}][{"float_value":10.0}][{"negative_value":-9223372036854775808,"positive_value":9223372036854775807}][{"very_small_floating_point_value":4.9E-324,"very_large_floating_point_value":1.7976931348623157E308}]
```

Boolean and null values are represented with the unquoted special keywords `true`, `false`, and `null`. The following examples of JSON strings demonstrate these possibilities.

```
[{"boolean_value_1":true,"boolean_value_2":false}][{"unknown_value":null}]
```

If you select a value of a BLOB type, the result is represented in the JSON string as a base64-encoded value. To convert the value back to its original representation, you can use the appropriate decoding function in your application's language. For example, in Java you call the function `Base64.getDecoder().decode()`. The following sample output shows the result of selecting a BLOB value of `hello world` and returning the result set as a JSON string.

```
[{"blob_column":"aGVsbG8gd29ybGQ="}]
```

The following Python example shows how to access the values from the result of a call to the Python `execute_statement` function. The result set is a string value in the field `response['formattedRecords']`. The code turns the JSON string into a data structure by calling the `json.loads` function. Then each row of the result set is a list element within the data structure, and within each row you can refer to each field of the result set by name.

```
import json

result = json.loads(response['formattedRecords'])
print (result[0]["id"])
```

The following Javascript example shows how to access the values from the result of a call to the Javascript `executeStatement` function. The result set is a string value in the field `response.formattedRecords`. The code turns the JSON string into a data structure by calling the `JSON.parse` function. Then each row of the result set is an array element within the data structure, and within each row you can refer to each field of the result set by name.

```
<script>
  const result = JSON.parse(response.formattedRecords);
  document.getElementById("display").innerHTML = result[0].id;
</script>
```

## Troubleshooting Data API issues

Use the following sections, titled with common error messages, to help troubleshoot problems that you have with the Data API.

## Topics

- [Transaction <transaction\\_ID> is not found \(p. 1609\)](#)
- [Packet for query is too large \(p. 1609\)](#)
- [Database response exceeded size limit \(p. 1609\)](#)
- [HttpEndpoint is not enabled for cluster <cluster\\_ID> \(p. 1609\)](#)

## Transaction <transaction\_ID> is not found

In this case, the transaction ID specified in a Data API call wasn't found. The cause for this issue is appended to the error message, and is one of the following:

- Transaction may be expired.

Make sure that each transactional call runs within three minutes of the previous one.

It's also possible that the specified transaction ID wasn't created by a [BeginTransaction](#) call. Make sure that your call has a valid transaction ID.

- One previous call resulted in a termination of your transaction.

The transaction was already ended by your [CommitTransaction](#) or [RollbackTransaction](#) call.

- Transaction has been aborted due to an error from a previous call.

Check whether your previous calls have thrown any exceptions.

For information about running transactions, see [Calling the Data API \(p. 1588\)](#).

## Packet for query is too large

In this case, the result set returned for a row was too large. The Data API size limit is 64 KB per row in the result set returned by the database.

To solve this issue, make sure that each row in a result set is 64 KB or less.

## Database response exceeded size limit

In this case, the size of the result set returned by the database was too large. The Data API limit is 1 MiB in the result set returned by the database.

To solve this issue, make sure that calls to the Data API return 1 MiB of data or less. If you need to return more than 1 MiB, you can use multiple [ExecuteStatement](#) calls with the `LIMIT` clause in your query.

For more information about the `LIMIT` clause, see [SELECT syntax](#) in the MySQL documentation.

## HttpEndpoint is not enabled for cluster <cluster\_ID>

Check the following potential causes for this issue:

- The Data API isn't enabled for the Aurora Serverless v1 DB cluster. To use the Data API with an Aurora Serverless v1 DB cluster, the Data API must be enabled for the DB cluster. For information about enabling the Data API, see [Enabling the Data API \(p. 1584\)](#).
- The DB cluster was renamed after the Data API was enabled for it. In that case, turn off the Data API for that cluster and then enable it again.

- The ARN you specified doesn't precisely match the ARN of the cluster. Check that the ARN returned from another source or constructed by program logic matches the ARN of the cluster exactly. For example, make sure that the ARN you use has the correct letter case for all alphabetic characters.

If the Data API has not been enabled for the DB cluster, enable it. Make sure that it's an Aurora Serverless v1 cluster. Currently, you can't use the Data API with Aurora Serverless v2.

If the DB cluster was renamed after the Data API was enabled for the DB cluster, disable the Data API and then enable it again.

For information about enabling the Data API, see [Enabling the Data API \(p. 1584\)](#).

## Logging Data API calls with AWS CloudTrail

Data API is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Data API. CloudTrail captures all API calls for Data API as events, including calls from the Amazon RDS console and from code calls to the Data API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Data API. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the data collected by CloudTrail, you can determine a lot of information. This information includes the request that was made to Data API, the IP address the request was made from, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](#).

## Working with Data API information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Data API, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing events with CloudTrail event history](#) in the [AWS CloudTrail User Guide](#).

For an ongoing record of events in your AWS account, including events for Data API, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in the [AWS CloudTrail User Guide](#):

- [Overview for creating a trail](#)
- [CloudTrail supported services and integrations](#)
- [Configuring Amazon SNS notifications for CloudTrail](#)
- [Receiving CloudTrail log files from multiple Regions](#) and [Receiving CloudTrail log files from multiple accounts](#)

All Data API operations are logged by CloudTrail and documented in the [Amazon RDS data service API reference](#). For example, calls to the `BatchExecuteStatement`, `BeginTransaction`, `CommitTransaction`, and `ExecuteStatement` operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.

- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity element](#).

## Understanding Data API log file entries

A *trail* is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An *event* represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `ExecuteStatement` operation.

```
{  
    "eventVersion": "1.05",  
    "userIdentity": {  
        "type": "IAMUser",  
        "principalId": "AKIAIOSFODNN7EXAMPLE",  
        "arn": "arn:aws:iam::123456789012:user/johndoe",  
        "accountId": "123456789012",  
        "accessKeyId": "AKIAI44QH8DHBEXAMPLE",  
        "userName": "johndoe"  
    },  
    "eventTime": "2019-12-18T00:49:34Z",  
    "eventSource": "rdsdata.amazonaws.com",  
    "eventName": "ExecuteStatement",  
    "awsRegion": "us-east-1",  
    "sourceIPAddress": "192.0.2.0",  
    "userAgent": "aws-cli/1.16.102 Python/3.7.2 Windows/10 botocore/1.12.92",  
    "requestParameters": {  
        "continueAfterTimeout": false,  
        "database": "*****",  
        "includeResultMetadata": false,  
        "parameters": [],  
        "resourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:my-database-1",  
        "schema": "*****",  
        "secretArn": "arn:aws:secretsmanager:us-east-1:123456789012:secret:dataapisecret-  
ABC123",  
        "sql": "*****"  
    },  
    "responseElements": null,  
    "requestID": "6ba9a36e-b3aa-4ca8-9a2e-15a9eada988e",  
    "eventID": "a2c7a357-ee8e-4755-a0d0-aed11ed4253a",  
    "eventType": "AwsApiCall",  
    "recipientAccountId": "123456789012"  
}
```

## Excluding Data API events from an AWS CloudTrail trail

Most Data API users rely on the events in an AWS CloudTrail trail to provide a record of Data API operations. The trail can be a valuable source of data for auditing critical events, such as a SQL statement that deleted rows in a table. In some cases, the metadata in a CloudTrail log entry can help you to avoid or resolve errors.

However, because the Data API can generate a large number of events, you can exclude Data API events from a CloudTrail trail. This per-trail setting excludes all Data API events. You can't exclude particular Data API events.

To exclude Data API events from a trail, do the following:

- In the CloudTrail console, choose the **Exclude Amazon RDS Data API events** setting when you [create a trail](#) or [update a trail](#).
- In the CloudTrail API, use the [PutEventSelectors](#) operation. Add the `ExcludeManagementEventSources` attribute to your event selectors with a value of `rdsdata.amazonaws.com`. For more information, see [Creating, updating, and managing trails with the AWS Command Line Interface](#) in the *AWS CloudTrail User Guide*.

**Warning**

Excluding Data API events from a CloudTrail log can obscure Data API actions. Be cautious when giving principals the `cloudtrail:PutEventSelectors` permission that is required to perform this operation.

You can turn off this exclusion at any time by changing the console setting or the event selectors for a trail. The trail will then start recording Data API events. However, it can't recover Data API events that occurred while the exclusion was effective.

When you exclude Data API events by using the console or API, the resulting CloudTrail `PutEventSelectors` API operation is also logged in your CloudTrail logs. If Data API events don't appear in your CloudTrail logs, look for a `PutEventSelectors` event with the `ExcludeManagementEventSources` attribute set to `rdsdata.amazonaws.com`.

For more information, see [Logging management events for trails](#) in the *AWS CloudTrail User Guide*.

# Using the query editor for Aurora Serverless v1

With the query editor for Aurora Serverless v1, you can run SQL queries in the RDS console. You can run any valid SQL statement on the Aurora Serverless v1 DB cluster, including data manipulation and data definition statements.

The query editor requires an Aurora Serverless v1 DB cluster with the Data API enabled. For information about creating an Aurora Serverless v1 DB cluster with the Data API enabled, see [Using the Data API for Aurora Serverless v1 \(p. 1581\)](#).

**Note**

The Data API and query editor aren't supported for Aurora Serverless v2.

## Availability of the query editor

The query editor is available only for Aurora Serverless v1 DB clusters using specific Aurora MySQL and Aurora PostgreSQL versions that support the Data API. The query editor is available only in AWS Regions where the Data API is supported. For more information, see [Data API for Aurora Serverless v1 \(p. 33\)](#).

## Authorizing access to the query editor

A user must be authorized to run queries in the query editor. You can authorize a user to run queries in the query editor by adding the `AmazonRDSDataFullAccess` policy, a predefined AWS Identity and Access Management (IAM) policy, to that user.

**Note**

Make sure to use the same user name and password when you create the IAM user as you did for the database user, such as the master user name and password. For more information, see [Creating an IAM user in your AWS account](#) in the *AWS Identity and Access Management User Guide*.

You can also create an IAM policy that grants access to the query editor. After you create the policy, add it to each user that requires access to the query editor.

The following policy provides the minimum required permissions for a user to access the query editor.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "QueryEditor0",  
            "Effect": "Allow",  
            "Action": [
```

```
        "secretsmanager:GetSecretValue",
        "secretsmanager:PutResourcePolicy",
        "secretsmanager:PutSecretValue",
        "secretsmanager>DeleteSecret",
        "secretsmanager:DescribeSecret",
        "secretsmanager:TagResource"
    ],
    "Resource": "arn:aws:secretsmanager:*::secret:rds-db-credentials/*"
},
{
    "Sid": "QueryEditor1",
    "Effect": "Allow",
    "Action": [
        "secretsmanager:GetRandomPassword",
        "tag:GetResources",
        "secretsmanager>CreateSecret",
        "secretsmanager>ListSecrets",
        "dbqms>CreateFavoriteQuery",
        "dbqms:DescribeFavoriteQueries",
        "dbqms:UpdateFavoriteQuery",
        "dbqms>DeleteFavoriteQueries",
        "dbqms:GetQueryString",
        "dbqms>CreateQueryHistory",
        "dbqms:UpdateQueryHistory",
        "dbqms>DeleteQueryHistory",
        "dbqms:DescribeQueryHistory",
        "rds-data:BatchExecuteStatement",
        "rds-data:BeginTransaction",
        "rds-data:CommitTransaction",
        "rds-data:ExecuteStatement",
        "rds-data:RollbackTransaction"
    ],
    "Resource": "*"
}
]
```

For information about creating an IAM policy, see [Creating IAM policies](#) in the *AWS Identity and Access Management User Guide*.

For information about adding an IAM policy to a user, see [Adding and removing IAM identity permissions](#) in the *AWS Identity and Access Management User Guide*.

## Running queries in the query editor

You can run SQL statements on an Aurora Serverless v1 DB cluster in the query editor.

### To run a query in the query editor

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the Aurora Serverless v1 DB clusters that you want to query.
3. In the navigation pane, choose **Databases**.
4. Choose the Aurora Serverless v1 DB cluster that you want to run SQL queries on.
5. For **Actions**, choose **Query**. If you haven't connected to the database before, the **Connect to database** page opens.

## Connect to database

You need to choose a database and enter the database credentials to use the query editor. We will be storing your credentials and the connection in the AWS Secrets Manager service. [Learn more](#)

Database instance or cluster

database-1

Database username

Add new database credentials

Enter database username

Enter database password

Enter the name of the database or schema (optional)

Enter the name for schemas collection

Enter database or schema name

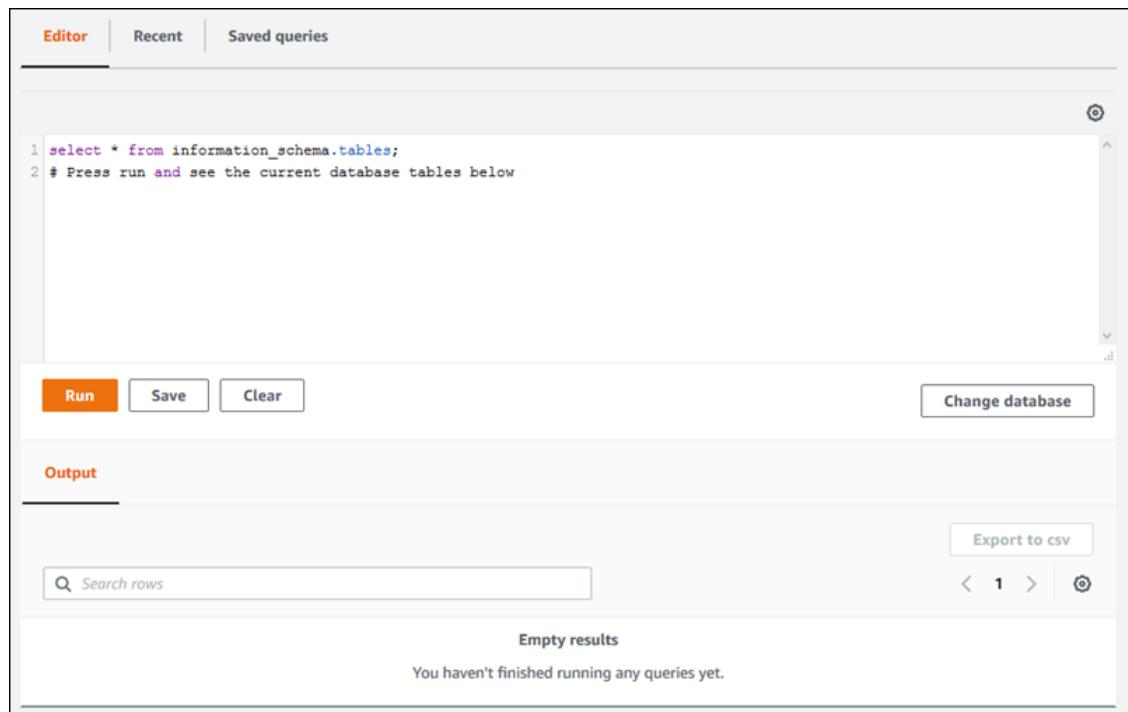

**Cancel** **Connect to database**

6. Enter the following information:
  - a. For **Database instance or cluster**, choose the Aurora Serverless v1 DB cluster that you want to run SQL queries on.
  - b. For **Database username**, choose the user name of the database user to connect with, or choose **Add new database credentials**. If you choose **Add new database credentials**, enter the user name for the new database credentials in **Enter database username**.
  - c. For **Enter database password**, enter the password for the database user that you chose.
  - d. In the last box, enter the name of the database or schema that you want to use for the Aurora DB cluster.
  - e. Choose **Connect to database**.

**Note**

If your connection is successful, your connection and authentication information are stored in AWS Secrets Manager. You don't need to enter the connection information again.

7. In the query editor, enter the SQL query that you want to run on the database.

```
1 select * from information_schema.tables;
2 # Press run and see the current database tables below
```

Run Save Clear Change database

Output

Search rows Export to csv

Empty results

You haven't finished running any queries yet.

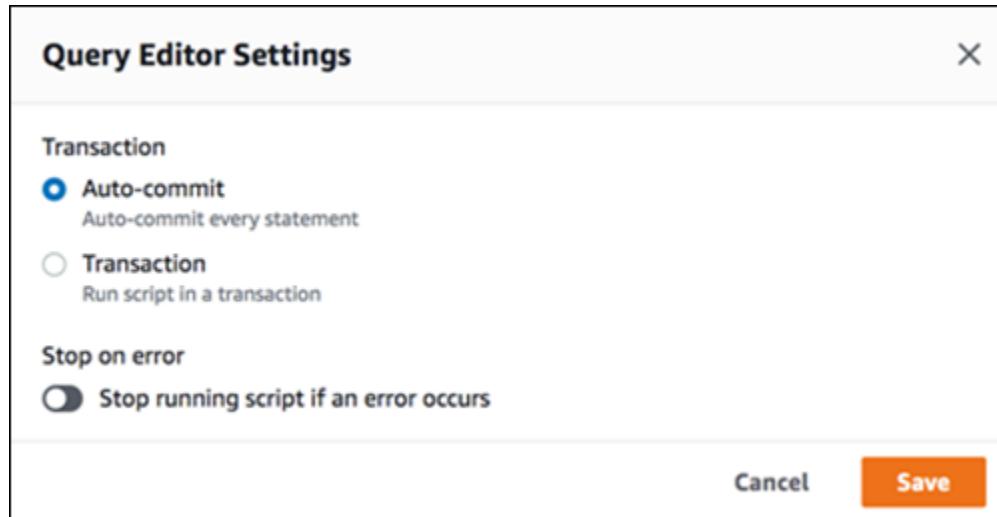

Each SQL statement can commit automatically, or you can run SQL statements in a script as part of a transaction. To control this behavior, choose the gear icon above the query window.

```
1 select * from information_schema.tables;
2 # Press run and see the current database tables below
```

Save Clear Change database

The **Query Editor Settings** window appears.

If you choose **Auto-commit**, every SQL statement commits automatically. If you choose **Transaction**, you can run a group of statements in a script. Statements are automatically committed at the end of the script unless explicitly committed or rolled back before then. Also, you can choose to stop a running script if an error occurs by enabling **Stop on error**.

**Note**

In a group of statements, data definition language (DDL) statements can cause previous data manipulation language (DML) statements to commit. You can also include COMMIT and ROLLBACK statements in a group of statements in a script.

After you make your choices in the **Query Editor Settings** window, choose **Save**.

8. Choose **Run** or press Ctrl+Enter, and the query editor displays the results of your query.

After running the query, save it to **Saved queries** by choosing **Save**.

Export the query results to spreadsheet format by choosing **Export to csv**.

You can find, edit, and rerun previous queries. To do so, choose the **Recent** tab or the **Saved queries** tab, choose the query text, and then choose **Run**.

To change the database, choose **Change database**.

## Database Query Metadata Service (DBQMS) API reference

The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.

The following DBQMS actions are supported:

**Topics**

- [CreateFavoriteQuery \(p. 1618\)](#)
- [CreateQueryHistory \(p. 1618\)](#)
- [CreateTab \(p. 1618\)](#)

- [DeleteFavoriteQueries \(p. 1618\)](#)
- [DeleteQueryHistory \(p. 1618\)](#)
- [DeleteTab \(p. 1618\)](#)
- [DescribeFavoriteQueries \(p. 1618\)](#)
- [DescribeQueryHistory \(p. 1618\)](#)
- [DescribeTabs \(p. 1618\)](#)
- [GetQueryString \(p. 1619\)](#)
- [UpdateFavoriteQuery \(p. 1619\)](#)
- [UpdateQueryHistory \(p. 1619\)](#)
- [UpdateTab \(p. 1619\)](#)

## CreateFavoriteQuery

Save a new favorite query. Each IAM user can create up to 1000 saved queries. This limit is subject to change in the future.

## CreateQueryHistory

Save a new query history entry.

## CreateTab

Save a new query tab. Each IAM user can create up to 10 query tabs.

## DeleteFavoriteQueries

Delete one or more saved queries.

## DeleteQueryHistory

Delete query history entries.

## DeleteTab

Delete query tab entries.

## DescribeFavoriteQueries

List saved queries created by an IAM user in a given account.

## DescribeQueryHistory

List query history entries.

## DescribeTabs

List query tabs created by an IAM user in a given account.

## GetQueryString

Retrieve full query text from a query ID.

## UpdateFavoriteQuery

Update the query string, description, name, or expiration date.

## UpdateQueryHistory

Update the status of query history.

## UpdateTab

Update the query tab name and query string.

# Best practices with Amazon Aurora

Following, you can find information on general best practices and options for using or migrating data to an Amazon Aurora DB cluster.

Some of the best practices for Amazon Aurora are specific to a particular database engine. For more information about Aurora best practices specific to a database engine, see the following.

Database engine	Best practices
Amazon Aurora MySQL	See <a href="#">Best practices with Amazon Aurora MySQL (p. 940)</a>
Amazon Aurora PostgreSQL	See <a href="#">Best practices with Amazon Aurora PostgreSQL (p. 1200)</a>

## Note

For common recommendations for Aurora, see [Viewing Amazon Aurora recommendations \(p. 444\)](#).

## Topics

- [Basic operational guidelines for Amazon Aurora \(p. 1620\)](#)
- [DB instance RAM recommendations \(p. 1620\)](#)
- [Monitoring Amazon Aurora \(p. 1621\)](#)
- [Working with DB parameter groups and DB cluster parameter groups \(p. 1621\)](#)
- [Amazon Aurora best practices presentation video \(p. 1621\)](#)

# Basic operational guidelines for Amazon Aurora

The following are basic operational guidelines that everyone should follow when working with Amazon Aurora. The Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Monitor your memory, CPU, and storage usage. You can set up Amazon CloudWatch to notify you when usage patterns change or when you approach the capacity of your deployment. This way, you can maintain system performance and availability.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. The underlying IP address of a DB instance can change after a failover. Thus, caching the DNS data for an extended time can lead to connection failures if your application tries to connect to an IP address that no longer is in service. Aurora DB clusters with multiple read replicas can experience connection failures also when connections use the reader endpoint and one of the read replica instances is in maintenance or is deleted.
- Test failover for your DB cluster to understand how long the process takes for your use case. Testing failover can help you ensure that the application that accesses your DB cluster can automatically connect to the new DB cluster after failover.

# DB instance RAM recommendations

To optimize performance, allocate enough RAM so that your working set resides almost completely in memory. To determine whether your working set is almost all in memory, examine the following metrics in Amazon CloudWatch:

- **VolumeReadIOPS** – This metric measures the average number of read I/O operations from a cluster volume, reported at 5-minute intervals. The value of **VolumeReadIOPS** should be small and stable. In some cases, you might find your read I/O is spiking or is higher than usual. If so, investigate the DB instances in your DB cluster to see which DB instances are causing the increased I/O.

**Tip**

If your Aurora MySQL cluster uses parallel query, you might see an increase in **VolumeReadIOPS** values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

- **BufferCacheHitRatio** – This metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB cluster. This metric gives you an insight into the amount of data that is being served from memory. If the hit ratio is low, it's a good indication that your queries on this DB instance are going to disk more often than not. In this case, investigate your workload to see which queries are causing this behavior.

If, after investigating your workload, you find that you need more memory, consider scaling up the DB instance class to a class with more RAM. After doing so, you can investigate the metrics discussed preceding and continue to scale up as necessary. If your Aurora cluster is larger than 40 TB, don't use db.t2, db.t3, or db.t4g instance classes.

For more information, see [Amazon CloudWatch metrics for Amazon Aurora \(p. 525\)](#).

## Monitoring Amazon Aurora

Amazon Aurora provides a variety of Amazon CloudWatch metrics that you can monitor to determine the health and performance of your Aurora DB cluster. You can use various tools, such as the AWS Management Console, AWS CLI, and CloudWatch API, to view Aurora metrics. For more information, see [Monitoring metrics in an Amazon Aurora cluster \(p. 427\)](#).

## Working with DB parameter groups and DB cluster parameter groups

We recommend that you try out DB parameter group and DB cluster parameter group changes on a test DB cluster before applying parameter group changes to your production DB cluster. Improperly setting DB engine parameters can have unintended adverse effects, including degraded performance and system instability.

Always use caution when modifying DB engine parameters, and back up your DB cluster before modifying a DB parameter group. For information about backing up your DB cluster, see [Backing up and restoring an Amazon Aurora DB cluster \(p. 368\)](#).

## Amazon Aurora best practices presentation video

The 2016 AWS Summit conference in Chicago included a presentation on best practices for creating and configuring an Amazon Aurora DB cluster to be more secure and highly available. For a video of the presentation, see [Amazon Aurora best practices](#) on the AWS YouTube channel.

# Performing a proof of concept with Amazon Aurora

Following, you can find an explanation of how to set up and run a proof of concept for Aurora. A *proof of concept* is an investigation that you do to see if Aurora is a good fit with your application. The proof of concept can help you understand Aurora features in the context of your own database applications and how Aurora compares with your current database environment. It can also show what level of effort you need to move data, port SQL code, tune performance, and adapt your current management procedures.

In this topic, you can find an overview and a step-by-step outline of the high-level procedures and decisions involved in running a proof of concept, listed following. For detailed instructions, you can follow links to the full documentation for specific subjects.

## Overview of an Aurora proof of concept

When you conduct a proof of concept for Amazon Aurora, you learn what it takes to port your existing data and SQL applications to Aurora. You exercise the important aspects of Aurora at scale, using a volume of data and activity that's representative of your production environment. The objective is to feel confident that the strengths of Aurora match up well with the challenges that cause you to outgrow your previous database infrastructure. At the end of a proof of concept, you have a solid plan to do larger-scale performance benchmarking and application testing. At this point, you understand the biggest work items on your way to a production deployment.

The following advice about best practices can help you avoid common mistakes that cause problems during benchmarking. However, this topic doesn't cover the step-by-step process of performing benchmarks and doing performance tuning. Those procedures vary depending on your workload and the Aurora features that you use. For detailed information, consult performance-related documentation such as [Managing performance and scaling for Aurora DB clusters \(p. 274\)](#), [Amazon Aurora MySQL performance enhancements \(p. 651\)](#), [Managing Amazon Aurora PostgreSQL \(p. 1143\)](#), and [Monitoring DB load with Performance Insights on Amazon Aurora \(p. 461\)](#).

The information in this topic applies mainly to applications where your organization writes the code and designs the schema and that support the MySQL and PostgreSQL open-source database engines. If you're testing a commercial application or code generated by an application framework, you might not have the flexibility to apply all of the guidelines. In such cases, check with your AWS representative to see if there are Aurora best practices or case studies for your type of application.

## 1. Identify your objectives

When you evaluate Aurora as part of a proof of concept, you choose what measurements to make and how to evaluate the success of the exercise.

You must ensure that all of the functionality of your application is compatible with Aurora. Because Aurora major versions are wire-compatible with corresponding major versions of MySQL and PostgreSQL, most applications developed for those engines are also compatible with Aurora. However, you must still validate compatibility on a per-application basis.

For example, some of the configuration choices that you make when you set up an Aurora cluster influence whether you can or should use particular database features. You might start with the most general-purpose kind of Aurora cluster, known as *provisioned*. You might then decide if a specialized configuration such as serverless or parallel query offers benefits for your workload.

Use the following questions to help identify and quantify your objectives:

- Does Aurora support all functional use cases of your workload?
- What dataset size or load level do you want? Can you scale to that level?
- What are your specific query throughput or latency requirements? Can you reach them?
- What is the minimum acceptable amount of planned or unplanned downtime for your workload? Can you achieve it?
- What are the necessary metrics for operational efficiency? Can you accurately monitor them?
- Does Aurora support your specific business goals, such as cost reduction, increase in deployment, or provisioning speed? Do you have a way to quantify these goals?
- Can you meet all security and compliance requirements for your workload?

Take some time to build knowledge about Aurora database engines and platform capabilities, and review the service documentation. Take note of all the features that can help you achieve your desired outcomes. One of these might be workload consolidation, described in the AWS Database Blog post [How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads](#). Another might be demand-based scaling, described in [Using Amazon Aurora Auto Scaling with Aurora replicas \(p. 305\)](#) in the *Amazon Aurora User Guide*. Others might be performance gains or simplified database operations.

## 2. Understand your workload characteristics

Evaluate Aurora in the context of your intended use case. Aurora is a good choice for online transaction processing (OLTP) workloads. You can also run reports on the cluster that holds the real-time OLTP data without provisioning a separate data warehouse cluster. You can recognize if your use case falls into these categories by checking for the following characteristics:

- High concurrency, with dozens, hundreds, or thousands of simultaneous clients.
- Large volume of low-latency queries (milliseconds to seconds).
- Short, real-time transactions.
- Highly selective query patterns, with index-based lookups.
- For HTAP, analytical queries that can take advantage of Aurora parallel query.

One of the key factors affecting your database choices is the velocity of the data. *High velocity* involves data being inserted and updated very frequently. Such a system might have thousands of connections and hundreds of thousands of simultaneous queries reading from and writing to a database. Queries in high-velocity systems usually affect a relatively small number of rows, and typically access multiple columns in the same row.

Aurora is designed to handle high-velocity data. Depending on the workload, an Aurora cluster with a single r4.16xlarge DB instance can process more than 600,000 SELECT statements per second. Again depending on workload, such a cluster can process 200,000 INSERT, UPDATE, and DELETE statements per second. Aurora is a row store database and is ideally suited for high-volume, high-throughput, and highly parallelized OLTP workloads.

Aurora can also run reporting queries on the same cluster that handles the OLTP workload. Aurora supports up to 15 [replicas \(p. 73\)](#), each of which is on average within 10–20 milliseconds of the primary

instance. Analysts can query OLTP data in real time without copying the data to a separate data warehouse cluster. With Aurora clusters using the parallel query feature, you can offload much of the processing, filtering, and aggregation work to the massively distributed Aurora storage subsystem.

Use this planning phase to familiarize yourself with the capabilities of Aurora, other AWS services, the AWS Management Console, and the AWS CLI. Also, check how these work with the other tooling that you plan to use in the proof of concept.

## 3. Practice with the AWS Management Console or AWS CLI

As a next step, practice with the AWS Management Console or the AWS CLI, to become familiar with these tools and with Aurora.

### Practice with the AWS Management Console

The following initial activities with Aurora database clusters are mainly so you can familiarize yourself with the AWS Management Console environment and practice setting up and modifying Aurora clusters. If you use the MySQL-compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

By taking advantage of the Aurora shared storage model and features such as replication and snapshots, you can treat entire database clusters as another kind of object that you freely manipulate. You can set up, tear down, and change the capacity of Aurora clusters frequently during the proof of concept. You aren't locked into early choices about capacity, database settings, and physical data layout.

To get started, set up an empty Aurora cluster. Choose the **provisioned** capacity type and **regional** location for your initial experiments.

Connect to that cluster using a client program such as a SQL command-line application. Initially, you connect using the cluster endpoint. You connect to that endpoint to perform any write operations, such as data definition language (DDL) statements and extract, transform, load (ETL) processes. Later in the proof of concept, you connect query-intensive sessions using the reader endpoint, which distributes the query workload among multiple DB instances in the cluster.

Scale the cluster out by adding more Aurora Replicas. For those procedures, see [Replication with Amazon Aurora \(p. 73\)](#). Scale the DB instances up or down by changing the AWS instance class. Understand how Aurora simplifies these kinds of operations, so that if your initial estimates for system capacity are inaccurate, you can adjust later without starting over.

Create a snapshot and restore it to a different cluster.

Examine cluster metrics to see activity over time, and how the metrics apply to the DB instances in the cluster.

It's useful to become familiar with how to do these things through the AWS Management Console in the beginning. After you understand what you can do with Aurora, you can progress to automating those operations using the AWS CLI. In the following sections, you can find more details about the procedures and best practices for these activities during the proof-of-concept period.

### Practice with the AWS CLI

We recommend automating deployment and management procedures, even in a proof-of-concept setting. To do so, become familiar with the AWS CLI if you're not already. If you use the MySQL-

compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

Aurora typically involves groups of DB instances arranged in clusters. Thus, many operations involve determining which DB instances are associated with a cluster and then performing administrative operations in a loop for all the instances.

For example, you might automate steps such as creating Aurora clusters, then scaling them up with larger instance classes or scaling them out with additional DB instances. Doing so helps you to repeat any stages in your proof of concept and explore what-if scenarios with different kinds or configurations of Aurora clusters.

Learn the capabilities and limitations of infrastructure deployment tools such as AWS CloudFormation. You might find activities that you do in a proof-of-concept context aren't suitable for production use. For example, the AWS CloudFormation behavior for modification is to create a new instance and delete the current one, including its data. For more details on this behavior, see [Update behaviors of stack resources](#) in the *AWS CloudFormation User Guide*.

## 4. Create your Aurora cluster

With Aurora, you can explore what-if scenarios by adding DB instances to the cluster and scaling up the DB instances to more powerful instance classes. You can also create clusters with different configuration settings to run the same workload side by side. With Aurora, you have a lot of flexibility to set up, tear down, and reconfigure DB clusters. Given this, it's helpful to practice these techniques in the early stages of the proof-of-concept process. For the general procedures to create Aurora clusters, see [Creating an Amazon Aurora DB cluster \(p. 127\)](#).

Where practical, start with a cluster using the following settings. Skip this step only if you have certain specific use cases in mind. For example, you might skip this step if your use case requires a specialized kind of Aurora cluster. Or you might skip it if you need a particular combination of database engine and version.

- Amazon Aurora.
- MySQL 5.7 compatibility. This combination of database engine and version has wide compatibility with other Aurora features and substantial customer usage for production applications.
- Turn off **Easy create**. For the proof of concept, we recommend that you be aware of all the settings you choose so that you can create identical or slightly different clusters later.
- Regional. The **Global** setting is for specific high availability scenarios. You can try it out later after your initial functional and performance experiments.
- One writer, multiple readers. This is the most widely used, general purpose kind of cluster. This setting persists for the life of the cluster. Thus, if you later do experiments with other kinds of clusters such as serverless or parallel query, you create other clusters and compare and contrast the results on each.
- Choose the **Dev/Test** template. This choice isn't significant for your proof-of-concept activities.
- For **DB instance class**, choose **Memory optimized classes** and one of the **xlarge** instance classes. You can adjust the instance class up or down later.
- Under **Multi-AZ Deployment**, choose **Create an Aurora Replica or Reader node in a different AZ**. Many of the most useful aspects of Aurora involve clusters of multiple DB instances. It makes sense to always start with at least two DB instances in any new cluster. Using a different Availability Zone for the second DB instance helps to test different high availability scenarios.
- When you pick names for the DB instances, use a generic naming convention. Don't refer to any cluster DB instance as the "master" or "writer," because different DB instances assume those roles as needed. We recommend using something like `clustername-az-serialnumber`, for example `myprodappdb-a-01`. These pieces uniquely identify the DB instance and its placement.

- Set the backup retention high for the Aurora cluster. With a long retention period, you can do point-in-time recovery (PITR) for a period up to 35 days. You can reset your database to a known state after running tests involving DDL and data manipulation language (DML) statements. You can also recover if you delete or change data by mistake.
- Turn on additional recovery, logging, and monitoring features at cluster creation. Turn on all the choices under **Backtrack**, **Performance Insights**, **Monitoring**, and **Log exports**. With these features enabled, you can test the suitability of features such as backtracking, Enhanced Monitoring, or Performance Insights for your workload. You can also easily investigate performance and perform troubleshooting during the proof of concept.

## 5. Set up your schema

On the Aurora cluster, set up databases, tables, indexes, foreign keys, and other schema objects for your application. If you're moving from another MySQL-compatible or PostgreSQL-compatible database system, expect this stage to be simple and straightforward. You use the same SQL syntax and command line or other client applications that you're familiar with for your database engine.

To issue SQL statements on your cluster, find its cluster endpoint and supply that value as the connection parameter to your client application. You can find the cluster endpoint on the [Connectivity](#) tab of the detail page of your cluster. The cluster endpoint is the one labeled **Writer**. The other endpoint, labeled **Reader**, represents a read-only connection that you can supply to end users who run reports or other read-only queries. For help with any issues around connecting to your cluster, see [Connecting to an Amazon Aurora DB cluster \(p. 207\)](#).

If you're porting your schema and data from a different database system, expect to make some schema changes at this point. These schema changes are to match the SQL syntax and capabilities available in Aurora. You might leave out certain columns, constraints, triggers, or other schema objects at this point. Doing so can be useful particularly if these objects require rework for Aurora compatibility and aren't significant for your objectives with the proof of concept.

If you're migrating from a database system with a different underlying engine than Aurora's, consider using the AWS Schema Conversion Tool (AWS SCT) to simplify the process. For details, see the [AWS Schema Conversion Tool User Guide](#). For general details about migration and porting activities, see the [Migrating Your Databases to Amazon Aurora](#) AWS whitepaper.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Such inefficiencies can be amplified when you deploy your application on a cluster with multiple DB instances and a heavy workload. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

## 6. Import your data

During the proof of concept, you bring across the data, or a representative sample, from your former database system. If practical, set up at least some data in each of your tables. Doing so helps to test compatibility of all data types and schema features. After you have exercised the basic Aurora features, scale up the amount of data. By the time you finish the proof of concept, you should test your ETL tools, queries, and overall workload with a dataset that's big enough to draw accurate conclusions.

You can use several techniques to import either physical or logical backup data to Aurora. For details, see [Migrating data to an Amazon Aurora MySQL DB cluster \(p. 690\)](#) or [Migrating data to Amazon Aurora with PostgreSQL compatibility \(p. 1048\)](#) depending on the database engine you're using in the proof of concept.

Experiment with the ETL tools and technologies that you're considering. See which one best meets your needs. Consider both throughput and flexibility. For example, some ETL tools perform a one-time transfer, and others involve ongoing replication from the old system to Aurora.

If you're migrating from a MySQL-compatible system to Aurora MySQL, you can use the native data transfer tools. The same applies if you're migrating from a PostgreSQL-compatible system to Aurora PostgreSQL. If you're migrating from a database system that uses a different underlying engine than Aurora does, you can experiment with the AWS Database Migration Service (AWS DMS). For details about AWS DMS, see the [AWS Database Migration Service User Guide](#).

For details about migration and porting activities, see the AWS whitepaper [Aurora migration handbook](#).

## 7. Port your SQL code

Trying out SQL and associated applications requires different levels of effort depending on different cases. In particular, the level of effort depends on whether you move from a MySQL-compatible or PostgreSQL-compatible system or another kind.

- If you're moving from RDS for MySQL or RDS for PostgreSQL, the SQL changes are small enough that you can try the original SQL code with Aurora and manually incorporate needed changes.
- Similarly, if you move from an on-premises database compatible with MySQL or PostgreSQL, you can try the original SQL code and manually incorporate changes.
- If you're coming from a different commercial database, the required SQL changes are more extensive. In this case, consider using the AWS SCT.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

You can verify the database connection logic in your application. To take advantage of Aurora distributed processing, you might need to use separate connections for read and write operations, and use relatively short sessions for query operations. For information about connections, see [9. Connect to Aurora \(p. 1628\)](#).

Consider if you had to make compromises and tradeoffs to work around issues in your production database. Build time into the proof-of-concept schedule to make improvements to your schema design and queries. To judge if you can achieve easy wins in performance, operating cost, and scalability, try the original and modified applications side by side on different Aurora clusters.

For details about migration and porting activities, see the AWS whitepaper [Aurora migration handbook](#).

## 8. Specify configuration settings

You can also review your database configuration parameters as part of the Aurora proof-of-concept exercise. You might already have MySQL or PostgreSQL configuration settings tuned for performance and scalability in your current environment. The Aurora storage subsystem is adapted and tuned for a distributed cloud-based environment with a high-speed storage subsystem. As a result, many former database engine settings don't apply. We recommend conducting your initial experiments with the default Aurora configuration settings. Reapply settings from your current environment only if you encounter performance and scalability bottlenecks. If you're interested, you can look more deeply into this subject in [Introducing the Aurora storage engine](#) on the AWS Database Blog.

Aurora makes it easy to reuse the optimal configuration settings for a particular application or use case. Instead of editing a separate configuration file for each DB instance, you manage sets of parameters that

you assign to entire clusters or specific DB instances. For example, the time zone setting applies to all DB instances in the cluster, and you can adjust the page cache size setting for each DB instance.

You start with one of the default parameter sets, and apply changes to only the parameters that you need to fine-tune. For details about working with parameter groups, see [Amazon Aurora DB cluster and DB instance parameters \(p. 217\)](#). For the configuration settings that are or aren't applicable to Aurora clusters, see [Aurora MySQL configuration parameters \(p. 949\)](#) or [Amazon Aurora PostgreSQL parameters \(p. 1369\)](#) depending on your database engine.

## 9. Connect to Aurora

As you find when doing your initial schema and data setup and running sample queries, you can connect to different endpoints in an Aurora cluster. The endpoint to use depends on whether the operation is a read such as `SELECT` statement, or a write such as a `CREATE` or `INSERT` statement. As you increase the workload on an Aurora cluster and experiment with Aurora features, it's important for your application to assign each operation to the appropriate endpoint.

By using the cluster endpoint for write operations, you always connect to a DB instance in the cluster that has read/write capability. By default, only one DB instance in an Aurora cluster has read/write capability. This DB instance is called the *primary instance*. If the original primary instance becomes unavailable, Aurora activates a failover mechanism and a different DB instance takes over as the primary.

Similarly, by directing `SELECT` statements to the reader endpoint, you spread the work of processing queries among the DB instances in the cluster. Each reader connection is assigned to a different DB instance using round-robin DNS resolution. Doing most of the query work on the read-only DB Aurora Replicas reduces the load on the primary instance, freeing it to handle DDL and DML statements.

Using these endpoints reduces the dependency on hard-coded hostnames, and helps your application to recover more quickly from DB instance failures.

### Note

Aurora also has custom endpoints that you create. Those endpoints usually aren't needed during a proof of concept.

The Aurora Replicas are subject to a replica lag, even though that lag is usually 10 to 20 milliseconds. You can monitor the replication lag and decide whether it is within the range of your data consistency requirements. In some cases, your read queries might require strong read consistency (read-after-write consistency). In these cases, you can continue using the cluster endpoint for them and not the reader endpoint.

To take full advantage of Aurora capabilities for distributed parallel execution, you might need to change the connection logic. Your objective is to avoid sending all read requests to the primary instance. The read-only Aurora Replicas are standing by, with all the same data, ready to handle `SELECT` statements. Code your application logic to use the appropriate endpoint for each kind of operation. Follow these general guidelines:

- Avoid using a single hard-coded connection string for all database sessions.
- If practical, enclose write operations such as DDL and DML statements in functions in your client application code. That way, you can make different kinds of operations use specific connections.
- Make separate functions for query operations. Aurora assigns each new connection to the reader endpoint to a different Aurora Replica to balance the load for read-intensive applications.
- For operations involving sets of queries, close and reopen the connection to the reader endpoint when each set of related queries is finished. Use connection pooling if that feature is available in your software stack. Directing queries to different connections helps Aurora to distribute the read workload among the DB instances in the cluster.

For general information about connection management and endpoints for Aurora, see [Connecting to an Amazon Aurora DB cluster \(p. 207\)](#). For a deep dive on this subject, see [Aurora MySQL database administrator's handbook – Connection management](#).

## 10. Run your workload

After the schema, data, and configuration settings are in place, you can begin exercising the cluster by running your workload. Use a workload in the proof of concept that mirrors the main aspects of your production workload. We recommend always making decisions about performance using real-world tests and workloads rather than synthetic benchmarks such as sysbench or TPC-C. Wherever practical, gather measurements based on your own schema, query patterns, and usage volume.

As much as practical, replicate the actual conditions under which the application will run. For example, you typically run your application code on Amazon EC2 instances in the same AWS Region and the same virtual private cloud (VPC) as the Aurora cluster. If your production application runs on multiple EC2 instances spanning multiple Availability Zones, set up your proof-of-concept environment in the same way. For more information on AWS Regions, see [Regions and Availability Zones](#) in the *Amazon RDS User Guide*. To learn more about the Amazon VPC service, see [What is Amazon VPC?](#) in the *Amazon VPC User Guide*.

After you've verified that the basic features of your application work and you can access the data through Aurora, you can exercise aspects of the Aurora cluster. Some features you might want to try are concurrent connections with load balancing, concurrent transactions, and automatic replication.

By this point, the data transfer mechanisms should be familiar, and so you can run tests with a larger proportion of sample data.

This stage is when you can see the effects of changing configuration settings such as memory limits and connection limits. Revisit the procedures that you explored in [8. Specify configuration settings \(p. 1627\)](#).

You can also experiment with mechanisms such as creating and restoring snapshots. For example, you can create clusters with different AWS instance classes, numbers of AWS Replicas, and so on. Then on each cluster, you can restore the same snapshot containing your schema and all your data. For the details of that cycle, see [Creating a DB cluster snapshot \(p. 373\)](#) and [Restoring from a DB cluster snapshot \(p. 375\)](#).

## 11. Measure performance

Best practices in this area are designed to ensure that all the right tools and processes are set up to quickly isolate abnormal behaviors during workload operations. They're also set up to see that you can reliably identify any applicable causes.

You can always see the current state of your cluster, or examine trends over time, by examining the **Monitoring** tab. This tab is available from the console detail page for each Aurora cluster or DB instance. It displays metrics from the Amazon CloudWatch monitoring service in the form of charts. You can filter the metrics by name, by DB instance, and by time period.

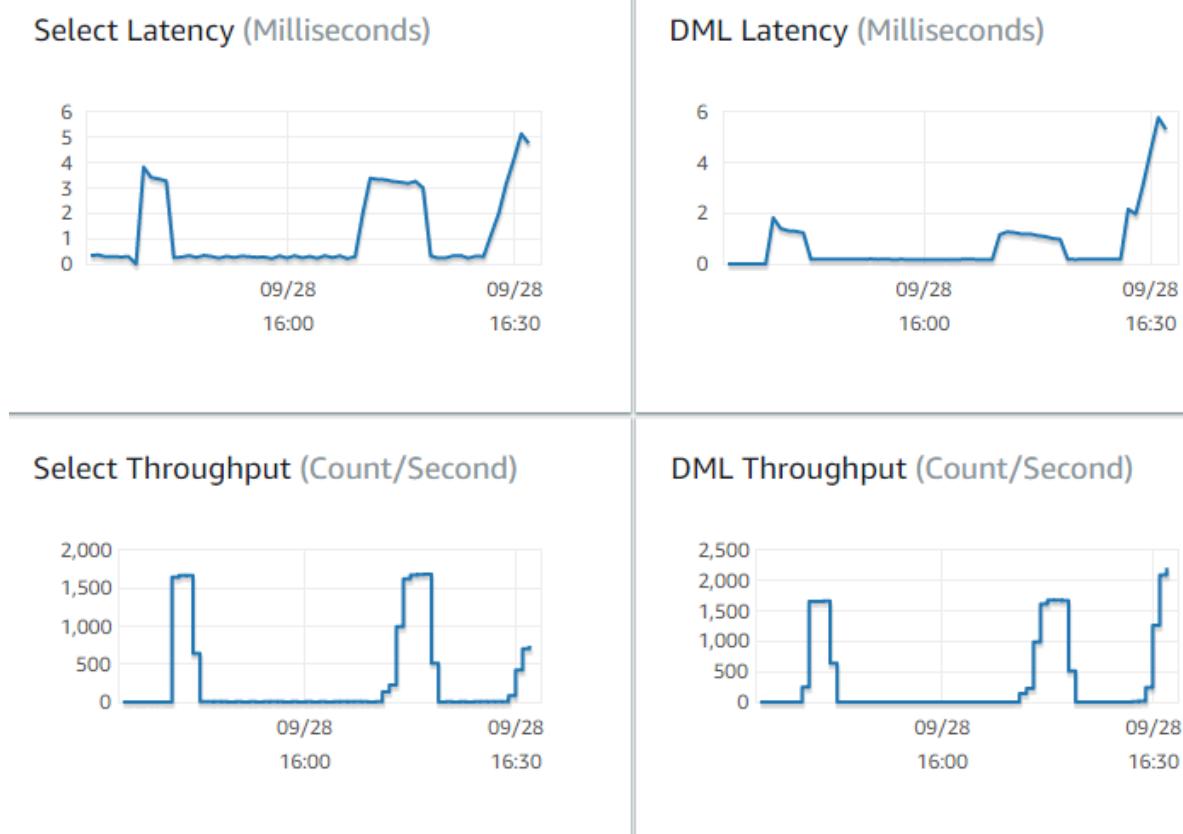

To have more choices on the **Monitoring** tab, enable Enhanced Monitoring and Performance Insights in the cluster settings. You can also enable those choices later if you didn't choose them when setting up the cluster.

To measure performance, you rely mostly on the charts showing activity for the whole Aurora cluster. You can verify whether the Aurora Replicas have similar load and response times. You can also see how the work is split up between the read/write primary instance and the read-only Aurora Replicas. If there is some imbalance between the DB instances or an issue affecting only one DB instance, you can examine the **Monitoring** tab for that specific instance.

After the environment and the actual workload are set up to emulate your production application, you can measure how well Aurora performs. The most important questions to answer are as follows:

- How many queries per second is Aurora processing? You can examine the **Throughput** metrics to see the figures for various kinds of operations.
- How long does it take, on average for Aurora to process a given query? You can examine the **Latency** metrics to see the figures for various kinds of operations.

To do so, look at the **Monitoring** tab for a given Aurora cluster in the [Amazon RDS console](#) as illustrated following.

If you can, establish baseline values for these metrics in your current environment. If that's not practical, construct a baseline on the Aurora cluster by executing a workload equivalent to your production application. For example, run your Aurora workload with a similar number of simultaneous users and queries. Then observe how the values change as you experiment with different instance classes, cluster size, configuration settings, and so on.

If the throughput numbers are lower than you expect, investigate further the factors affecting database performance for your workload. Similarly, if the latency numbers are higher than you expect, further investigate. To do so, monitor the secondary metrics for the DB server (CPU, memory, and so on). You can see whether the DB instances are close to their limits. You can also see how much extra capacity your DB instances have to handle more concurrent queries, queries against larger tables, and so on.

**Tip**

To detect metric values that fall outside the expected ranges, set up CloudWatch alarms.

When evaluating the ideal Aurora cluster size and capacity, you can find the configuration that achieves peak application performance without over-provisioning resources. One important factor is finding

the appropriate size for the DB instances in the Aurora cluster. Start by selecting an instance size that has similar CPU and memory capacity to your current production environment. Collect throughput and latency numbers for the workload at that instance size. Then, scale the instance up to the next larger size. See if the throughput and latency numbers improve. Also scale the instance size down, and see if the latency and throughput numbers remain the same. Your goal is to get the highest throughput, with the lowest latency, on the smallest instance possible.

**Tip**

Size your Aurora clusters and associated DB instances with enough existing capacity to handle sudden, unpredictable traffic spikes. For mission-critical databases, leave at least 20 percent spare CPU and memory capacity.

Run performance tests long enough to measure database performance in a warm, steady state. You might need to run the workload for many minutes or even a few hours before reaching this steady state. It's normal at the beginning of a run to have some variance. This variance happens because each Aurora Replica warms up its caches based on the `SELECT` queries that it handles.

Aurora performs best with transactional workloads involving multiple concurrent users and queries. To ensure that you're driving enough load for optimal performance, run benchmarks that use multithreading, or run multiple instances of the performance tests concurrently. Measure performance with hundreds or even thousands of concurrent client threads. Simulate the number of concurrent threads that you expect in your production environment. You might also perform additional stress tests with more threads to measure Aurora scalability.

## 12. Exercise Aurora high availability

Many of the main Aurora features involve high availability. These features include automatic replication, automatic failover, automatic backups with point-in-time restore, and ability to add DB instances to the cluster. The safety and reliability from features like these are important for mission-critical applications.

To evaluate these features requires a certain mindset. In earlier activities, such as performance measurement, you observe how the system performs when everything works correctly. Testing high availability requires you to think through worst-case behavior. You must consider various kinds of failures, even if such conditions are rare. You might intentionally introduce problems to make sure that the system recovers correctly and quickly.

**Tip**

For a proof of concept, set up all the DB instances in an Aurora cluster with the same AWS instance class. Doing so makes it possible to try out Aurora availability features without major changes to performance and scalability as you take DB instances offline to simulate failures.

We recommend using at least two instances in each Aurora cluster. The DB instances in an Aurora cluster can span up to three Availability Zones (AZs). Locate each of the first two or three DB instances in a different AZ. When you begin using larger clusters, spread your DB instances across all of the AZs in your AWS Region. Doing so increases fault tolerance capability. Even if a problem affects an entire AZ, Aurora can fail over to a DB instance in a different AZ. If you run a cluster with more than three instances, distribute the DB instances as evenly as you can over all three AZs.

**Tip**

The storage for an Aurora cluster is independent from the DB instances. The storage for each Aurora cluster always spans three AZs.

When you test high availability features, always use DB instances with identical capacity in your test cluster. Doing so avoids unpredictable changes in performance, latency, and so on whenever one DB instance takes over for another.

To learn how to simulate failure conditions to test high availability features, see [Testing Amazon Aurora using fault injection queries \(p. 738\)](#).

As part of your proof-of-concept exercise, one objective is to find the ideal number of DB instances and the optimal instance class for those DB instances. Doing so requires balancing the requirements of high availability and performance.

For Aurora, the more DB instances that you have in a cluster, the greater the benefits for high availability. Having more DB instances also improves scalability of read-intensive applications. Aurora can distribute multiple connections for `SELECT` queries among the read-only Aurora Replicas.

On the other hand, limiting the number of DB instances reduces the replication traffic from the primary node. The replication traffic consumes network bandwidth, which is another aspect of overall performance and scalability. Thus, for write-intensive OLTP applications, prefer to have a smaller number of large DB instances rather than many small DB instances.

In a typical Aurora cluster, one DB instance (the primary instance) handles all the DDL and DML statements. The other DB instances (the Aurora Replicas) handle only `SELECT` statements. Although the DB instances don't do exactly the same amount of work, we recommend using the same instance class for all the DB instances in the cluster. That way, if a failure happens and Aurora promotes one of the read-only DB instances to be the new primary instance, the primary instance has the same capacity as before.

If you need to use DB instances of different capacities in the same cluster, set up failover tiers for the DB instances. These tiers determine the order in which Aurora Replicas are promoted by the failover mechanism. Put DB instances that are a lot larger or smaller than the others into a lower failover tier. Doing so ensures that they are chosen last for promotion.

Exercise the data recovery features of Aurora, such as automatic point-in-time restore, manual snapshots and restore, and cluster backtracking. If appropriate, copy snapshots to other AWS Regions and restore into other AWS Regions to mimic DR scenarios.

Investigate your organization's requirements for restore time objective (RTO), restore point objective (RPO), and geographic redundancy. Most organizations group these items under the broad category of disaster recovery. Evaluate the Aurora high availability features described in this section in the context of your disaster recovery process to ensure that your RTO and RPO requirements are met.

## 13. What to do next

At the end of a successful proof-of-concept process, you confirm that Aurora is a suitable solution for you based on the anticipated workload. Throughout the preceding process, you've checked how Aurora works in a realistic operational environment and measured it against your success criteria.

After you get your database environment up and running with Aurora, you can move on to more detailed evaluation steps, leading to your final migration and production deployment. Depending on your situation, these other steps might or might not be included in the proof-of-concept process. For details about migration and porting activities, see the AWS whitepaper [Aurora migration handbook](#).

In another next step, consider the security configurations relevant for your workload and designed to meet your security requirements in a production environment. Plan what controls to put in place to protect access to the Aurora cluster master user credentials. Define the roles and responsibilities of database users to control access to data stored in the Aurora cluster. Take into account database access requirements for applications, scripts, and third-party tools or services. Explore AWS services and features such as AWS Secrets Manager and AWS Identity and Access Management (IAM) authentication.

At this point, you should understand the procedures and best practices for running benchmark tests with Aurora. You might find you need to do additional performance tuning. For details, see [Managing performance and scaling for Aurora DB clusters \(p. 274\)](#), [Amazon Aurora MySQL performance enhancements \(p. 651\)](#), [Managing Amazon Aurora PostgreSQL \(p. 1143\)](#), and [Monitoring DB load with Performance Insights on Amazon Aurora \(p. 461\)](#). If you do additional tuning, make sure that you're

familiar with the metrics that you gathered during the proof of concept. For a next step, you might create new clusters with different choices for configuration settings, database engine, and database version. Or you might create specialized kinds of Aurora clusters to match the needs of specific use cases.

For example, you can explore Aurora parallel query clusters for hybrid transaction/analytical processing (HTAP) applications. If wide geographic distribution is crucial for disaster recovery or to minimize latency, you can explore Aurora global databases. If your workload is intermittent or you're using Aurora in a development/test scenario, you can explore Aurora Serverless clusters.

Your production clusters might also need to handle high volumes of incoming connections. To learn those techniques, see the AWS whitepaper [Aurora MySQL database administrator's handbook – Connection management](#).

If, after the proof of concept, you decide that your use case is not suited for Aurora, consider these other AWS services:

- For purely analytic use cases, workloads benefit from a columnar storage format and other features more suitable to OLAP workloads. AWS services that address such use cases include the following:
  - [Amazon Redshift](#)
  - [Amazon EMR](#)
  - [Amazon Athena](#)
- Many workloads benefit from a combination of Aurora with one or more of these services. You can move data between these services by using these:
  - [AWS Glue](#)
  - [AWS DMS](#)
  - [Importing from Amazon S3](#), as described in the *Amazon Aurora User Guide*
  - [Exporting to Amazon S3](#), as described in the *Amazon Aurora User Guide*
  - Many other popular ETL tools

# Security in Amazon Aurora

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security of the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the [AWS compliance programs](#). To learn about the compliance programs that apply to Amazon Aurora (Aurora), see [AWS services in scope by compliance program](#).
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon Aurora. The following topics show you how to configure Amazon Aurora to meet your security and compliance objectives. You also learn how to use other AWS services that help you monitor and secure your Amazon Aurora resources.

You can manage access to your Amazon Aurora resources and your databases on a DB cluster. The method you use to manage access depends on what type of task the user needs to perform with Amazon Aurora:

- Run your DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB cluster in a VPC, see [Amazon VPC VPCs and Amazon Aurora \(p. 1729\)](#).
- Use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon Aurora resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB clusters, tag resources, or modify security groups.

For information on setting up an IAM user, see [Create an IAM user \(p. 87\)](#).

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB cluster. When you first create a DB cluster, its firewall prevents any database access except through rules specified by an associated security group.
- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB clusters running the Aurora MySQL or Aurora PostgreSQL. For more information on using SSL/TLS with a DB cluster, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).
- Use Amazon Aurora encryption to secure your DB clusters and snapshots at rest. Amazon Aurora encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB cluster. For more information, see [Encrypting Amazon Aurora resources \(p. 1638\)](#).
- Use the security features of your DB engine to control who can log in to the databases on a DB cluster. These features work just as if the database was on your local network.

For information about security with Aurora MySQL, see [Security with Amazon Aurora MySQL \(p. 681\)](#).

For information about security with Aurora PostgreSQL, see [Security with Amazon Aurora PostgreSQL \(p. 1018\)](#).

Aurora is part of the managed database service Amazon Relational Database Service (Amazon RDS). Amazon RDS is a web service that makes it easier to set up, operate, and scale a relational database in the cloud. If you are not already familiar with Amazon RDS, see the [Amazon RDS user guide](#).

Aurora includes a high-performance storage subsystem. Its MySQL- and PostgreSQL-compatible database engines are customized to take advantage of that fast distributed storage. Aurora also automates and standardizes database clustering and replication, which are typically among the most challenging aspects of database configuration and administration.

For both Amazon RDS and Aurora, you can access the RDS API programmatically, and you can use the AWS CLI to access the RDS API interactively. Some RDS API operations and AWS CLI commands apply to both Amazon RDS and Aurora, while others apply to either Amazon RDS or Aurora. For information about RDS API operations, see [Amazon RDS API reference](#). For more information about the AWS CLI, see [AWS Command Line Interface reference for Amazon RDS](#).

**Note**

You have to configure security only for your use cases. You don't have to configure security access for processes that Amazon Aurora manages. These include creating backups, automatic failover, and other processes.

For more information on managing access to Amazon Aurora resources and your databases on a DB cluster, see the following topics.

## Database authentication with Amazon Aurora

Amazon Aurora supports several ways to authenticate database users.

Password authentication is available by default for all DB clusters. For Aurora MySQL, you can also add IAM database authentication. For Aurora PostgreSQL, you can also add either or both IAM database authentication and Kerberos authentication for the same DB cluster.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the `rds_iam` role to the user.
- To use Kerberos authentication, assign the `rds_ad` role to the user.
- To use password authentication, don't assign either the `rds_iam` or `rds_ad` roles to the user.

Don't assign both the `rds_iam` and `rds_ad` roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the `rds_iam` role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

#### Topics

- [Password authentication \(p. 1636\)](#)
- [IAM database authentication \(p. 1636\)](#)
- [Kerberos authentication \(p. 1636\)](#)

## Password authentication

With *password authentication*, your database performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is `CREATE USER name IDENTIFIED BY password`, while in PostgreSQL, the statement is `CREATE USER name WITH PASSWORD password`.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with AWS Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon Aurora, see [Creating a basic secret](#) and [Rotating secrets for supported Amazon RDS databases](#) in the *AWS Secrets Manager User Guide*. For information about programmatically retrieving your secrets in your custom applications, see [Retrieving the secret value](#) in the *AWS Secrets Manager User Guide*.

## IAM database authentication

You can authenticate to your DB cluster using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with Aurora MySQL and Aurora PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see [IAM database authentication \(p. 1683\)](#).

## Kerberos authentication

Amazon Aurora supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon Aurora support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB clusters.

You can make it possible for your database users to authenticate against DB clusters in two ways. They can use credentials stored either in AWS Directory Service for Microsoft Active Directory or in your on-premises Active Directory.

Currently, Aurora supports Kerberos authentication for Aurora PostgreSQL DB clusters. With Kerberos authentication, Aurora PostgreSQL DB clusters support one- and two-way forest trust relationships. For more information, see [Using Kerberos authentication with Aurora PostgreSQL \(p. 1035\)](#).

## Data protection in Amazon RDS

The AWS [shared responsibility model](#) applies to data protection in Amazon Relational Database Service. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the [Data Privacy FAQ](#). For information about data protection in Europe, see the [AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog](#).

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing personal data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-2](#).

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form fields such as a **Name** field. This includes when you work with Amazon RDS or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

### Topics

- [Protecting data using encryption \(p. 1637\)](#)
- [Internetwork traffic privacy \(p. 1652\)](#)

## Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB clusters.

### Topics

- [Encrypting Amazon Aurora resources \(p. 1638\)](#)

- [AWS KMS key management \(p. 1641\)](#)
- [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#)
- [Rotating your SSL/TLS certificate \(p. 1644\)](#)

## Encrypting Amazon Aurora resources

Amazon Aurora can encrypt your Amazon Aurora DB clusters. Data that is encrypted at rest includes the underlying storage for DB clusters, its automated backups, read replicas, and snapshots.

Amazon Aurora encrypted DB clusters use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon Aurora DB clusters. After your data is encrypted, Amazon Aurora handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

### Note

For encrypted and unencrypted DB clusters, data that is in transit between the source and the read replicas is encrypted, even when replicating across AWS Regions.

### Topics

- [Overview of encrypting Amazon Aurora resources \(p. 1638\)](#)
- [Encrypting an Amazon Aurora DB cluster \(p. 1638\)](#)
- [Determining whether encryption is turned on for a DB cluster \(p. 1639\)](#)
- [Availability of Amazon Aurora encryption \(p. 1640\)](#)
- [Limitations of Amazon Aurora encrypted DB clusters \(p. 1640\)](#)

## Overview of encrypting Amazon Aurora resources

Amazon Aurora encrypted DB clusters provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon Aurora encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest.

For an Amazon Aurora encrypted DB cluster, all DB instances, logs, backups, and snapshots are encrypted. You can also encrypt a read replica of an Amazon Aurora encrypted cluster. Amazon Aurora uses an AWS KMS key to encrypt these resources. For more information about KMS keys, see [AWS KMS keys](#) in the *AWS Key Management Service Developer Guide*. Each DB instance in the DB cluster is encrypted using the same KMS key as the DB cluster. If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.

You can use an AWS managed key, or you can create customer managed keys. To manage the customer managed keys used for encrypting and decrypting your Amazon Aurora resources, you use the [AWS Key Management Service \(AWS KMS\)](#). AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Using AWS KMS, you can create customer managed keys and define the policies that control how these customer managed keys can be used. AWS KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported AWS services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with AWS KMS, see [AWS Service Integration](#).

## Encrypting an Amazon Aurora DB cluster

To encrypt a new DB cluster, choose **Enable encryption** on the console. For information on creating a DB cluster, see [Creating an Amazon Aurora DB cluster \(p. 127\)](#).

If you use the [create-db-cluster](#) AWS CLI command to create an encrypted DB cluster, set the `--storage-encrypted` parameter. If you use the [CreateDBCluster](#) API operation, set the `StorageEncrypted` parameter to true.

When you create an encrypted DB cluster, you can choose a customer managed key or the AWS managed key for Amazon Aurora to encrypt your DB cluster. If you don't specify the key identifier for a customer managed key, Amazon Aurora uses the AWS managed key for your new DB cluster. Amazon Aurora creates an AWS managed key for Amazon Aurora for your AWS account. Your AWS account has a different AWS managed key for Amazon Aurora for each AWS Region.

Once you have created an encrypted DB cluster, you can't change the KMS key used by that DB cluster. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB cluster.

If you use the AWS CLI `create-db-cluster` command to create an encrypted DB cluster with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key. If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to any key identifier for the KMS key. To use a customer managed key in a different AWS account, specify the key ARN or alias ARN.

### Important

Amazon Aurora can lose access to the KMS key for a DB cluster. For example, Aurora loses access when the KMS key isn't enabled, or when Aurora access to a KMS key is revoked. In these cases, the encrypted DB cluster goes into `inaccessible-encryption-credentials-recoverable` state. The DB cluster remains in this state for seven days. When you start the DB cluster during that time, it checks if the KMS key is active and recovers the DB cluster if it is. Restart the DB cluster using the AWS CLI command [start-db-cluster](#). Currently, you can't start a DB cluster in this state using the AWS Management Console.

If the DB cluster isn't recovered, then it goes into the terminal `inaccessible-encryption-credentials` state. In this case, you can only restore the DB cluster from a backup. We strongly recommend that you always turn on backups for encrypted DB instances to guard against the loss of encrypted data in your databases.

## Determining whether encryption is turned on for a DB cluster

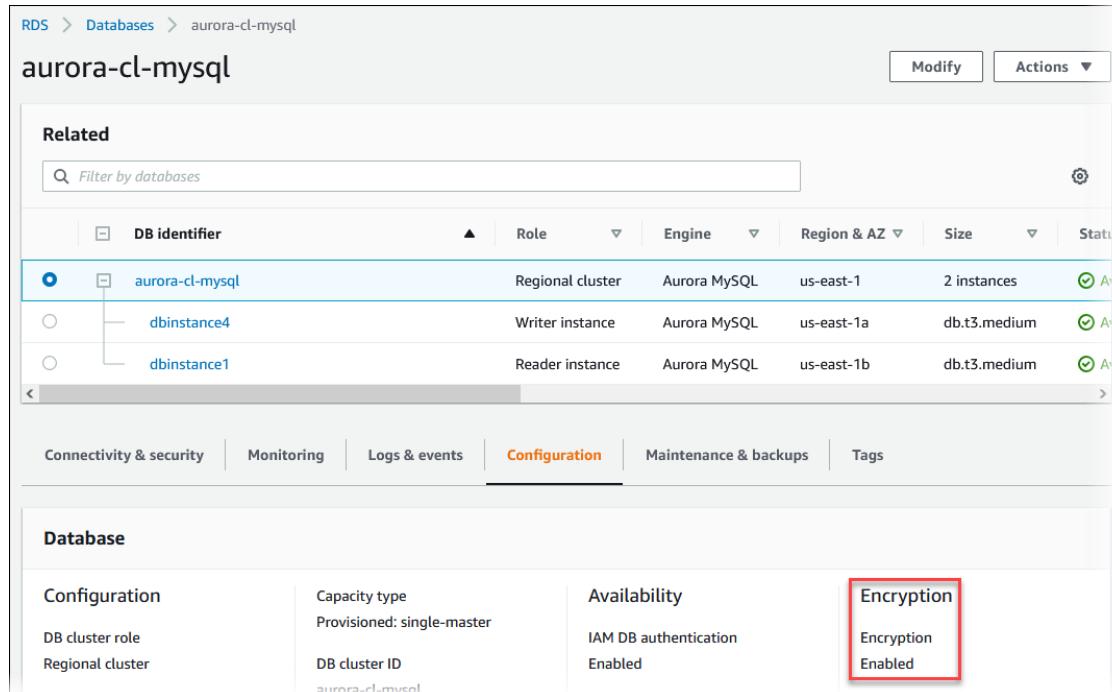

You can use the AWS Management Console, AWS CLI, or RDS API to determine whether encryption at rest is turned on for a DB cluster.

### Console

#### To determine whether encryption at rest is turned on for a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB cluster that you want to check to view its details.
4. Choose the **Configuration** tab and check the **Encryption** value.

It shows either **Enabled** or **Not enabled**.

The screenshot shows the AWS RDS 'Databases' page for the 'aurora-cl-mysql' cluster. The 'Configuration' tab is selected. In the 'Database' section, under the 'Encryption' heading, it says 'Encryption Enabled'. This section is highlighted with a red box.

DB identifier	Role	Engine	Region & AZ	Size	Status
aurora-cl-mysql	Regional cluster	Aurora MySQL	us-east-1	2 instances	<span>Enabled</span>
dbinstance4	Writer instance	Aurora MySQL	us-east-1a	db.t3.medium	<span>Enabled</span>
dbinstance1	Reader instance	Aurora MySQL	us-east-1b	db.t3.medium	<span>Enabled</span>

## AWS CLI

To determine whether encryption at rest is turned on for a DB cluster by using the AWS CLI, call the [describe-db-clusters](#) command with the following option:

- `--db-cluster-identifier` – The name of the DB cluster.

The following example uses a query to return either `TRUE` or `FALSE` regarding encryption at rest for the `mydb` DB cluster.

### Example

```
aws rds describe-db-clusters --db-cluster-identifier mydb --query "[].{StorageEncrypted:StorageEncrypted}" --output text
```

## RDS API

To determine whether encryption at rest is turned on for a DB cluster by using the Amazon RDS API, call the [DescribeDBClusters](#) operation with the following parameter:

- `DBClusterIdentifier` – The name of the DB cluster.

## Availability of Amazon Aurora encryption

Amazon Aurora encryption is currently available for all database engines and storage types.

### Note

Amazon Aurora encryption is not available for the db.t2.micro DB instance class.

## Limitations of Amazon Aurora encrypted DB clusters

The following limitations exist for Amazon Aurora encrypted DB clusters:

- You can't turn off encryption on an encrypted DB cluster.
- You can't create an encrypted snapshot of an unencrypted DB cluster.
- A snapshot of an encrypted DB cluster must be encrypted using the same KMS key as the DB cluster.
- You can't convert an unencrypted DB cluster to an encrypted one. However, you can restore an unencrypted snapshot to an encrypted Aurora DB cluster. To do this, specify a KMS key when you restore from the unencrypted snapshot.
- You can't create an encrypted Aurora Replica from an unencrypted Aurora DB cluster. You can't create an unencrypted Aurora Replica from an encrypted Aurora DB cluster.
- To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.

The source snapshot remains encrypted throughout the copy process. Amazon Aurora uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see [Envelope encryption](#) in the *AWS Key Management Service Developer Guide*.

- You can't unencrypt an encrypted DB cluster. However, you can export data from an encrypted DB cluster and import the data into an unencrypted DB cluster.

## AWS KMS key management

Amazon Aurora automatically integrates with AWS Key Management Service (AWS KMS) for key management. Amazon Aurora uses envelope encryption. For more information about envelope encryption, see [Envelope encryption](#) in the *AWS Key Management Service Developer Guide*.

An *AWS KMS key* is a logical representation of a key. The KMS key includes metadata, such as the key ID, creation date, description, and key state. The KMS key also contains the key material used to encrypt and decrypt data. For more information about KMS keys, see [AWS KMS keys](#) in the *AWS Key Management Service Developer Guide*.

You can manage KMS keys used for Amazon Aurora encrypted DB clusters using the [AWS Key Management Service \(AWS KMS\)](#) in the [AWS KMS console](#), the AWS CLI, or the AWS KMS API. If you want full control over a KMS key, then you must create a customer managed key. For more information about customer managed keys, see [Customer managed keys](#) in the *AWS Key Management Service Developer Guide*.

*AWS managed keys* are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. You can't delete, edit, or rotate AWS managed keys. For more information about AWS managed keys, see [AWS managed keys](#) in the *AWS Key Management Service Developer Guide*.

You can't share a snapshot that has been encrypted using the AWS managed key of the AWS account that shared the snapshot.

You can view audit logs of every action taken with an AWS managed or customer managed key by using [AWS CloudTrail](#).

### Important

If you turn off or revoke permissions to a KMS key used by an RDS database, RDS puts your database into a terminal state when access to the KMS key is required. This change could be immediate, or deferred, depending on the use case that required access to the KMS key. In this state, the DB cluster is no longer available, and the current state of the database can't be recovered. To restore the DB cluster, you must re-enable access to the KMS key for RDS, and then restore the DB cluster from the latest available backup.

## Authorizing use of a customer managed key

When Aurora uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the Aurora resource.

To create an Aurora resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- kms>CreateGrant
- kms>DescribeKey

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

You can make the IAM policy stricter in various ways. For example, to allow the customer managed key to be used only for requests that originate in Aurora, you can use the [kms:ViaService condition key](#) with the rds.<region>.amazonaws.com value.

You can also use the keys or values in the [encryption context](#) as a condition for using the customer managed key for cryptographic operations.

For more information, see [Allowing users in other accounts to use a KMS key](#) in the *AWS Key Management Service Developer Guide*.

## Using SSL/TLS to encrypt a connection to a DB cluster

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB cluster running Aurora MySQL or Aurora PostgreSQL.

SSL/TLS connections provide one layer of security by encrypting data that moves between your client and a DB cluster. Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon Aurora DB cluster. It does so by checking the server certificate that is automatically installed on all DB clusters that you provision.

Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your DB cluster, use the link following that corresponds to your DB engine:

- [Security with Amazon Aurora MySQL \(p. 681\)](#)
- [Security with Amazon Aurora PostgreSQL \(p. 1018\)](#)

### Note

All certificates are only available for download using SSL/TLS connections.

To get a certificate bundle that contains both the intermediate and root certificates for all AWS Regions, download from <https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem>.

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at <https://truststore.pki.rds.amazonaws.com/global/global-bundle.p7b>.

### Note

Amazon RDS Proxy and Aurora Serverless use certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see [Using TLS/SSL with RDS Proxy \(p. 1435\)](#).

If you are Aurora Serverless, downloading Amazon RDS certificates isn't required. For more information about using TLS/SSL with Aurora Serverless, see [Using TLS/SSL with Aurora Serverless v1 \(p. 1546\)](#).

## Certificate bundles for AWS Regions

To get a certificate bundle that contains both the intermediate and root certificates for an AWS Region, download from the link for the AWS Region in the following table.

AWS Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
US East (N. Virginia)	us-east-1-bundle.pem	us-east-1-bundle.p7b
US East (Ohio)	us-east-2-bundle.pem	us-east-2-bundle.p7b
US West (N. California)	us-west-1-bundle.pem	us-west-1-bundle.p7b
US West (Oregon)	us-west-2-bundle.pem	us-west-2-bundle.p7b
Africa (Cape Town)	af-south-1-bundle.pem	af-south-1-bundle.p7b
Asia Pacific (Hong Kong)	ap-east-1-bundle.pem	ap-east-1-bundle.p7b
Asia Pacific (Jakarta)	ap-southeast-3-bundle.pem	ap-southeast-3-bundle.p7b
Asia Pacific (Mumbai)	ap-south-1-bundle.pem	ap-south-1-bundle.p7b
Asia Pacific (Osaka)	ap-northeast-3-bundle.pem	ap-northeast-3-bundle.p7b
Asia Pacific (Tokyo)	ap-northeast-1-bundle.pem	ap-northeast-1-bundle.p7b
Asia Pacific (Seoul)	ap-northeast-2-bundle.pem	ap-northeast-2-bundle.p7b
Asia Pacific (Singapore)	ap-southeast-1-bundle.pem	ap-southeast-1-bundle.p7b
Asia Pacific (Sydney)	ap-southeast-2-bundle.pem	ap-southeast-2-bundle.p7b
Canada (Central)	ca-central-1-bundle.pem	ca-central-1-bundle.p7b
Europe (Frankfurt)	eu-central-1-bundle.pem	eu-central-1-bundle.p7b
Europe (Ireland)	eu-west-1-bundle.pem	eu-west-1-bundle.p7b
Europe (London)	eu-west-2-bundle.pem	eu-west-2-bundle.p7b
Europe (Milan)	eu-south-1-bundle.pem	eu-south-1-bundle.p7b
Europe (Paris)	eu-west-3-bundle.pem	eu-west-3-bundle.p7b
Europe (Stockholm)	eu-north-1-bundle.pem	eu-north-1-bundle.p7b
Middle East (Bahrain)	me-south-1-bundle.pem	me-south-1-bundle.p7b
South America (São Paulo)	sa-east-1-bundle.pem	sa-east-1-bundle.p7b

## AWS GovCloud (US) certificates

To get a certificate bundle that contains both the intermediate and root certificates for the AWS GovCloud (US) Regions, download from <https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.pem>.

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at <https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.p7b>.

To get a certificate bundle that contains both the intermediate and root certificates for an AWS GovCloud (US) Region, download from the link for the AWS GovCloud (US) Region in the following table.

AWS GovCloud (US) Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
AWS GovCloud (US-East)	<a href="#">us-gov-east-1-bundle.pem</a>	<a href="#">us-gov-east-1-bundle.p7b</a>
AWS GovCloud (US-West)	<a href="#">us-gov-west-1-bundle.pem</a>	<a href="#">us-gov-west-1-bundle.p7b</a>

## Rotating your SSL/TLS certificate

As of March 5, 2020, Amazon RDS CA-2015 certificates have expired. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances, you require Amazon RDS CA-2019 certificates, which are enabled by default for new DB instances. If you currently do not use SSL/TLS with certificate verification, you might still have expired CA-2015 certificates and must update them to CA-2019 certificates if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Follow these instructions to complete your updates. Before you update your DB instances to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).

### Note

Amazon RDS Proxy and Aurora Serverless use certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see [Using TLS/SSL with RDS Proxy \(p. 1435\)](#).

If you are Aurora Serverless, rotating your SSL/TLS certificate isn't required. For more information about using TLS/SSL with Aurora Serverless, see [Using TLS/SSL with Aurora Serverless v1 \(p. 1546\)](#).

### Note

If you are using a Go version 1.15 application with a DB instance that was created or updated to the `rds-ca-2019` certificate prior to July 28, 2020, you must update the certificate again. Run the `modify-db-instance` command shown in the AWS CLI section using `rds-ca-2019` as the CA certificate identifier. In this case, it isn't possible to update the certificate using the AWS Management Console. If you created your DB instance or updated its certificate after July 28, 2020, no action is required. For more information, see [Go GitHub issue #39568](#).

### Topics

- [Updating your CA certificate by modifying your DB instance \(p. 1644\)](#)
- [Updating your CA certificate by applying DB instance maintenance \(p. 1647\)](#)
- [Sample script for importing certificates into your trust store \(p. 1651\)](#)

## Updating your CA certificate by modifying your DB instance

Complete the following steps to update your CA certificate.

### To update your CA certificate by modifying your DB instance

1. Download the new SSL/TLS certificate as described in [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).

2. Update your applications to use the new SSL/TLS certificate.

The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

- [Updating applications to connect to Aurora MySQL DB clusters using new SSL/TLS certificates \(p. 687\)](#)
- [Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates \(p. 1032\)](#)

For a sample script that updates a trust store for a Linux operating system, see [Sample script for importing certificates into your trust store \(p. 1651\)](#).

**Note**

The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the AWS Database Migration Service to migrate a database to a DB cluster, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance to change the CA from **rds-ca-2015** to **rds-ca-2019**.

**Important**

By default, this operation restarts your DB instance. If you don't want to restart your DB instance during this operation, you can use the `modify-db-instance` CLI command and specify the `--no-certificate-rotation-restart` option.

This option will not rotate the certificate until the next time the database restarts, either for planned or unplanned maintenance. This option is only recommended if you don't use SSL/TLS.

If you are experiencing connectivity issues after certificate expiry, use the `apply immediately` option by specifying **Apply immediately** in the console or by specifying the `--apply-immediately` option using the AWS CLI. By default, this operation is scheduled to run during your next maintenance window.

You can use the AWS Management Console or the AWS CLI to change the CA certificate from **rds-ca-2015** to **rds-ca-2019** for a DB instance.

[Console](#)

**To change the CA from rds-ca-2015 to rds-ca-2019 for a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.

The screenshot shows the AWS RDS console with the path: RDS > Databases > aurora-test > dbinstance1. The main title is "dbinstance1". On the right, there is a red box highlighting the "More" button. Below the title, the "Related" section displays a table of database instances:

DB identifier	Role	Engine	Region & AZ	Size
aurora-test	Regional	Aurora MySQL	us-east-1	3 instances
dbinstance4	Writer	Aurora MySQL	us-east-1a	db.r5.large
dbinstance1	Reader	Aurora MySQL	us-east-1b	db.r5.large
dbinstance2	Reader	Aurora MySQL	us-east-1b	db.r5.large

Below the table, there are tabs: Connectivity & security (selected), Monitoring, Logs & events, Configuration, Maintenance, and Tags.

The **Modify DB Instance** page appears.

- In the **Connectivity** section, choose **rds-ca-2019**.

**Certificate authority**  
Certificate authority for this DB instance

rds-ca-2019

rds-ca-2015

rds-ca-2019

EC2 instances and devices outside of the VPC hosting the DB instance will connect to the DB instances. You can add more VPC security groups that specify which EC2 instances and devices can connect to the DB instance.

- Choose **Continue** and check the summary of modifications.
- To apply the changes immediately, choose **Apply immediately**.

**Important**

Choosing this option restarts your database immediately.

- On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

**Important**

When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

## AWS CLI

To use the AWS CLI to change the CA from `rds-ca-2015` to `rds-ca-2019` for a DB instance, call the `modify-db-instance` command. Specify the DB instance identifier and the `--ca-certificate-identifier` option.

**Important**

When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

### Example

The following code modifies `mydbinstance` by setting the CA certificate to `rds-ca-2019`. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately.

**Important**

By default, this operation reboots your DB instance. If you don't want to reboot your DB instance during this operation, you can use the `modify-db-instance` CLI command and specify the `--no-certificate-rotation-restart` option.

This option will not rotate the certificate until the next time the database restarts, either for planned or unplanned maintenance. This option is only recommended if you do not use SSL/TLS.

Use `--apply-immediately` to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--ca-certificate-identifier rds-ca-2019 \
--no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--ca-certificate-identifier rds-ca-2019 ^
--no-apply-immediately
```

## Updating your CA certificate by applying DB instance maintenance

Complete the following steps to update your CA certificate by applying DB instance maintenance.

### To update your CA certificate by applying DB instance maintenance

1. Download the new SSL/TLS certificate as described in [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).
2. Update your database applications to use the new SSL/TLS certificate.

The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

- [Updating applications to connect to Aurora MySQL DB clusters using new SSL/TLS certificates \(p. 687\)](#)
- [Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates \(p. 1032\)](#)

For a sample script that updates a trust store for a Linux operating system, see [Sample script for importing certificates into your trust store \(p. 1651\)](#).

**Note**

The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period.

3. Apply DB instance maintenance to change the CA from **rds-ca-2015** to **rds-ca-2019**.

**Important**

You can choose to apply the change immediately. By default, this operation is scheduled to run during your next maintenance window.

You can use the AWS Management Console to apply DB instance maintenance to change the CA certificate from **rds-ca-2015** to **rds-ca-2019** for multiple DB instances.

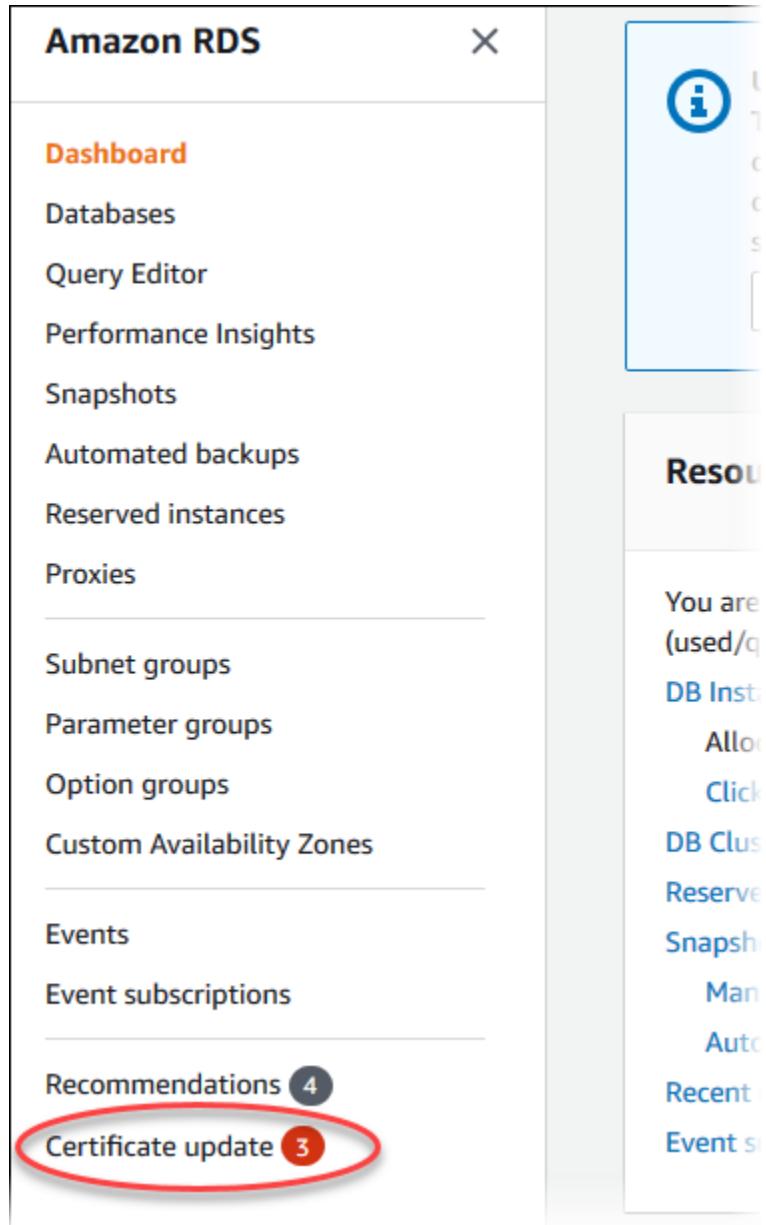

[Updating your CA certificate by applying maintenance to multiple DB instances](#)

Use the AWS Management Console to change the CA certificate for multiple DB instances.

**To change the CA from rds-ca-2015 to rds-ca-2019 for multiple DB instances**

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

In the navigation pane, there is a **Certificate update** option that shows the total number of affected DB instances.

Choose **Certificate update** in the navigation pane.

The **Update your Amazon RDS SSL/TLS certificates** page appears.

DB identifier	DB cluster identifier	Status	Apply date
mydbinstancecf	-	Requires Update	-
mydbinstancecf2	-	Requires Update	-
oracledb	-	Requires Update	-

**Note**

This page only shows the DB instances for the current AWS Region. If you have DB instances in more than one AWS Region, check this page in each AWS Region to see all DB instances with old SSL/TLS certificates.

3. Choose the DB instance you want to update.

You can schedule the certificate rotation for your next maintenance window by choosing **Update at the next maintenance window**. Apply the rotation immediately by choosing **Update now**.

**Important**

When your CA certificate is rotated, the operation restarts your DB instance.

If you experience connectivity issues after certificate expiry, use the **Update now** option.

4. If you choose **Update at the next maintenance window** or **Update now**, you are prompted to confirm the CA certificate rotation.

**Important**

Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. To determine whether your applications use SSL/TLS and the server certificate to connect, see [Step 2: Update Your Database Applications to Use the New SSL/TLS Certificate \(p. 1647\)](#). After you have updated these client applications, you can confirm the CA certificate rotation.

**Confirm rotation of CA certificate?**

Before scheduling the CA certificate rotation, update client applications that connect to your database to use the new CA certificate. Not doing this will cause an interruption of connectivity between your applications and your database. [Get new CA certificates](#)

I understand that not doing so will break SSL/TLS connectivity to my database.

**Cancel**

**Confirm**

To continue, choose the check box, and then choose **Confirm**.

5. Repeat steps 3 and 4 for each DB instance that you want to update.

## Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Each sample shell script uses keytool, which is part of the Java Development Kit (JDK). For information about installing the JDK, see [JDK Installation Guide](#).

### Topics

- [Sample script for importing certificates on Linux \(p. 1651\)](#)
- [Sample script for importing certificates on macOS \(p. 1651\)](#)

### Sample script for importing certificates on Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
storepassword=changeit

curl -ss "https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem" > ${mydir}/
global-bundle.pem
awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/ {split_after=1}{print
> "rds-ca-" n ".pem"}' < ${mydir}/global-bundle.pem

for CERT in rds-ca-*; do
alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
echo "Importing $alias"
keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -keystore
${truststore} -noprompt
rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias | cut -d
" " -f3- | while read alias
do
expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -alias
"${alias}" | grep Valid | perl -ne 'if(/until: (.*)\n/) { print "$1\n"; }'`^
echo " Certificate ${alias} expires in '$expiry'"^
done
```

### Sample script for importing certificates on macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
```

```
mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
storepassword=changeit

curl -sS "https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem" > ${mydir}/
global-bundle.pem
split -p "-----BEGIN CERTIFICATE-----" ${mydir}/global-bundle.pem rds-ca-
for CERT in rds-ca-*; do
    alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
    echo "Importing $alias"
    keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -keystore
${truststore} -noprompt
    rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias | cut -d
" " -f3- | while read alias
do
    expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -alias
"${alias}" | grep Valid | perl -ne 'if(/until: (.*)\n/) { print "$1\n"; }'`^
    echo " Certificate ${alias} expires in '$expiry'"
done
```

## Internetwork traffic privacy

Connections are protected both between Amazon Aurora and on-premises applications and between Amazon Aurora and other AWS resources within the same AWS Region.

## Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see [What is AWS Site-to-Site VPN?](#)
- An AWS Direct Connect connection. For more information, see [What is AWS Direct Connect?](#)

You get access to Amazon Aurora through the network by using AWS-published API operations. Clients must support Transport Layer Security (TLS) 1.0. We recommend TLS 1.2. Clients must also support cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, you must sign requests using an access key identifier and a secret access key that are associated with an IAM principal. Or you can use the [AWS security token service \(STS\)](#) to generate temporary security credentials to sign requests.

# Identity and access management for Amazon Aurora

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon RDS resources. IAM is an AWS service that you can use with no additional charge.

## Topics

- [Audience \(p. 1653\)](#)
- [Authenticating with identities \(p. 1653\)](#)
- [Managing access using policies \(p. 1655\)](#)
- [How Amazon Aurora works with IAM \(p. 1657\)](#)
- [Identity-based policy examples for Amazon Aurora \(p. 1662\)](#)
- [AWS managed policies for Amazon RDS \(p. 1673\)](#)
- [Amazon RDS updates to AWS managed policies \(p. 1679\)](#)
- [Preventing cross-service confused deputy problems \(p. 1681\)](#)
- [IAM database authentication \(p. 1683\)](#)
- [Troubleshooting Amazon Aurora identity and access \(p. 1710\)](#)

## Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work you do in Amazon Aurora.

**Service user** – If you use the Aurora service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Aurora features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Aurora, see [Troubleshooting Amazon Aurora identity and access \(p. 1710\)](#).

**Service administrator** – If you're in charge of Aurora resources at your company, you probably have full access to Aurora. It's your job to determine which Aurora features and resources your employees should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Aurora, see [How Amazon Aurora works with IAM \(p. 1657\)](#).

**IAM administrator** – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to Aurora. To view example Aurora identity-based policies that you can use in IAM, see [Identity-based policy examples for Amazon Aurora \(p. 1662\)](#).

## Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. For more information about signing in using the AWS Management Console, see [The IAM console and sign-in page](#) in the *IAM User Guide*.

You must be *authenticated* (signed in to AWS) as the AWS account root user, an IAM user, or by assuming an IAM role. You can also use your company's single sign-on authentication, or even sign in using Google or Facebook. In these cases, your administrator previously set up identity federation using IAM roles. When you access AWS using credentials from another company, you are assuming a role indirectly.

To sign in directly to the [AWS Management Console](#), use your password with your root user email or your IAM user name. You can access AWS programmatically using your root user or IAM user access keys. AWS provides SDK and command line tools to cryptographically sign your request using your credentials. If you don't use AWS tools, you must sign the request yourself. Do this using *Signature Version 4*, a protocol for authenticating inbound API requests. For more information about authenticating requests, see [Signature Version 4 signing process](#) in the [AWS General Reference](#).

Regardless of the authentication method that you use, you might also be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see [Using multi-factor authentication \(MFA\) in AWS](#) in the [IAM User Guide](#).

## AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the *AWS account root user* and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see [Tasks that require root user credentials](#) in the [AWS General Reference](#).

## IAM users and groups

An *IAM user* is an identity within your AWS account that has specific permissions for a single person or application. An IAM user can have long-term credentials such as a user name and password or a set of access keys. To learn how to generate access keys, see [Managing access keys for IAM users](#) in the [IAM User Guide](#). When you generate access keys for an IAM user, make sure you view and securely save the key pair. You cannot recover the secret access key in the future. Instead, you must generate a new access key pair.

An *IAM group* is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMAdmins* and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see [When to create an IAM user \(instead of a role\)](#) in the [IAM User Guide](#).

You can authenticate to your DB cluster using IAM database authentication.

IAM database authentication works with Aurora. For more information about authenticating to your DB cluster using IAM, see [IAM database authentication \(p. 1683\)](#).

## IAM roles

An *IAM role* is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by [switching roles](#). You can assume a role by calling an AWS CLI or AWS API

operation or by using a custom URL. For more information about methods for using roles, see [Using IAM roles](#) in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary IAM user permissions** – An IAM user can assume an IAM role to temporarily take on different permissions for a specific task.
- **Federated user access** – Instead of creating an IAM user, you can use existing identities from AWS Directory Service, your enterprise user directory, a web identity provider, or the IAM Identity Center identity store. These identities are known as *federated identities*. To assign permissions to federated identities, you can create a role and define permissions for the role. When an external identity authenticates, the identity is associated with the role and is granted the permissions that are defined by it. If you use IAM Identity Center, you configure a permission set. IAM Identity Center correlates the permission set to a role in IAM to control what your identities can access after they authenticate. For more information about identity federation, see [Creating a role for a third-party Identity Provider](#) in the *IAM User Guide*. For more information about IAM Identity Center, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide*.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
- **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see [Actions, Resources, and Condition Keys for Amazon RDS](#) in the *Service Authorization Reference*.
- **Service role** – A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.
- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *IAM User Guide*.

To learn whether to use IAM roles, see [When to create an IAM role \(instead of a user\)](#) in the *IAM User Guide*.

## Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions.

AWS evaluates these policies when an entity (root user, IAM user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see [Overview of JSON policies](#) in the *IAM User Guide*.

An IAM administrator can use policies to specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM entity (user or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

## Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, role, or group. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see [Choosing between managed policies and inline policies](#) in the *IAM User Guide*.

For information about AWS managed policies that are specific to Amazon Aurora, see [AWS managed policies for Amazon RDS \(p. 1673\)](#).

## Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#) in the *IAM User Guide*.
- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see [How SCPs work](#) in the *AWS Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see [Session policies](#) in the *IAM User Guide*.

## Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the *IAM User Guide*.

## How Amazon Aurora works with IAM

Before you use IAM to manage access to Amazon Aurora, you should understand what IAM features are available to use with Aurora.

### IAM features you can use with Amazon Aurora

IAM feature	Amazon Aurora support
Identity-based policies ( <a href="#">p. 1658</a> )	Yes
Resource-based policies ( <a href="#">p. 1658</a> )	No
Policy actions ( <a href="#">p. 1658</a> )	Yes
Policy resources ( <a href="#">p. 1659</a> )	Yes
Policy condition keys (service-specific) ( <a href="#">p. 1660</a> )	Yes
ACLs ( <a href="#">p. 1660</a> )	No
Attribute-based access control (ABAC) (tags in policies) ( <a href="#">p. 1661</a> )	Yes
Temporary credentials ( <a href="#">p. 1661</a> )	Yes
Principal permissions ( <a href="#">p. 1661</a> )	Yes
Service roles ( <a href="#">p. 1662</a> )	Yes
Service-linked roles ( <a href="#">p. 1662</a> )	Yes

To get a high-level view of how Amazon Aurora and other AWS services work with IAM, see [AWS services that work with IAM](#) in the *IAM User Guide*.

## Aurora identity-based policies

Supports identity-based policies	Yes
----------------------------------	-----

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see [IAM JSON policy elements reference](#) in the *IAM User Guide*.

### Identity-based policy examples for Aurora

To view examples of Aurora identity-based policies, see [Identity-based policy examples for Amazon Aurora](#) (p. 1662).

## Resource-based policies within Aurora

Supports resource-based policies	No
----------------------------------	----

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#) in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

## Policy actions for Aurora

Supports policy actions	Yes
-------------------------	-----

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The **Action** element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Aurora use the following prefix before the action: `rds:`. For example, to grant someone permission to describe DB instances with the Amazon RDS `DescribeDBInstances` API operation, you include the `rds:DescribeDBInstances` action in their policy. Policy statements must include either an `Action` or `NotAction` element. Aurora defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```
"Action": [  
    "rds:action1",  
    "rds:action2"]
```

You can specify multiple actions using wildcards (\*). For example, to specify all actions that begin with the word `Describe`, include the following action.

```
"Action": "rds:Describe*"
```

To see a list of Aurora actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

## Policy resources for Aurora

Supports policy resources	Yes
---------------------------	-----

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a `Resource` or a `NotResource` element. As a best practice, specify a resource using its [Amazon Resource Name \(ARN\)](#). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (\*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

The DB instance resource has the following Amazon Resource Name (ARN).

```
arn:${Partition}:rds:${Region}:${Account}:{ResourceType}/${Resource}
```

For more information about the format of ARNs, see [Amazon Resource Names \(ARNs\) and AWS service namespaces](#).

For example, to specify the `dbtest` DB instance in your statement, use the following ARN.

```
"Resource": "arn:aws:rds:us-west-2:123456789012:db:dbtest"
```

To specify all DB instances that belong to a specific account, use the wildcard (\*).

```
"Resource": "arn:aws:rds:us-east-1:123456789012:db:/*"
```

Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (\*).

```
"Resource": "*"
```

Many Amazon RDS API operations involve multiple resources. For example, `CreateDBInstance` creates a DB instance. You can specify that an IAM user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [  
    "resource1",  
    "resource2"]
```

To see a list of Aurora resource types and their ARNs, see [Resources Defined by Amazon RDS](#) in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see [Actions Defined by Amazon RDS](#).

## Policy condition keys for Aurora

Supports service-specific policy condition keys	Yes
---	-----

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element (or *Condition block*) lets you specify conditions in which a statement is in effect. The `Condition` element is optional. You can create conditional expressions that use [condition operators](#), such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see [IAM policy elements: variables and tags](#) in the *IAM User Guide*.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see [AWS global condition context keys](#) in the *IAM User Guide*.

Aurora defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see [AWS global condition context keys](#) in the *IAM User Guide*.

All RDS API operations support the `aws:RequestedRegion` condition key.

To see a list of Aurora condition keys, see [Condition Keys for Amazon RDS](#) in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see [Actions Defined by Amazon RDS](#).

## Access control lists (ACLs) in Aurora

Supports access control lists (ACLs)	No
--------------------------------------	----

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

## Attribute-based access control (ABAC) in policies with Aurora tags

Supports attribute-based access control (ABAC) tags in policies	Yes
---	-----

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the [condition element](#) of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

For more information about ABAC, see [What is ABAC?](#) in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see [Use attribute-based access control \(ABAC\)](#) in the *IAM User Guide*.

For more information about tagging Aurora resources, see [Specifying conditions: Using custom tags \(p. 1669\)](#). To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see [Grant permission for actions on a resource with a specific tag with two different values \(p. 1666\)](#).

## Using temporary credentials with Aurora

Supports temporary credentials	Yes
--------------------------------	-----

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see [AWS services that work with IAM](#) in the *IAM User Guide*.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see [Switching to a role \(console\)](#) in the *IAM User Guide*.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see [Temporary security credentials in IAM](#).

## Cross-service principal permissions for Aurora

Supports principal permissions	Yes
--------------------------------	-----

When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see [Actions, Resources, and Condition Keys for Amazon RDS](#) in the *Service Authorization Reference*.

## Service roles for Aurora

Supports service roles	Yes
------------------------	-----

A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

### Warning

Changing the permissions for a service role might break Aurora functionality. Edit service roles only when Aurora provides guidance to do so.

## Service-linked roles for Aurora

Supports service-linked roles	Yes
-------------------------------	-----

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about using Aurora service-linked roles, see [Using service-linked roles for Amazon Aurora](#) (p. 1724).

## Identity-based policy examples for Amazon Aurora

By default, IAM users and roles don't have permission to create or modify Aurora resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see [Creating policies on the JSON tab](#) in the *IAM User Guide*.

- Specifying conditions: Using custom tags (p. 1669)

## Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see [AWS managed policies](#) or [AWS managed policies for job functions](#) in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](#) in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see [IAM JSON policy elements: Condition](#) in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or root users in your account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see [Configuring MFA-protected API access](#) in the *IAM User Guide*.

For more information about best practices in IAM, see [Security best practices in IAM](#) in the *IAM User Guide*.

## Using the Aurora console

To access the Amazon Aurora console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon Aurora resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (IAM users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To ensure that those entities can still use the Aurora console, also attach the following AWS managed policy to the entities.

AmazonRDSReadOnlyAccess
-------------------------

For more information, see [Adding permissions to a user](#) in the *IAM User Guide*.

## Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "ViewOwnUserInfo",  
            "Effect": "Allow",  
            "Action": [  
                "iam:GetUserPolicy",  
                "iam>ListGroupsForUser",  
                "iam>ListAttachedUserPolicies",  
                "iam>ListUserPolicies",  
                "iam GetUser"  
            ],  
            "Resource": ["arn:aws:iam::*:user/${aws:username}"]  
        },  
        {  
            "Sid": "NavigateInConsole",  
            "Effect": "Allow",  
            "Action": [  
                "iam:GetGroupPolicy",  
                "iam:GetPolicyVersion",  
                "iam GetPolicy",  
                "iam>ListAttachedGroupPolicies",  
                "iam>ListGroupPolicies",  
                "iam>ListPolicyVersions",  
                "iam>ListPolicies",  
                "iam>ListUsers"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

## Allow a user to create DB instances in an AWS account

The following is an example policy that allows the user with the ID 123456789012 to create DB instances for your AWS account. The policy requires that the name of the new DB instance begin with test. The new DB instance must also use the MySQL database engine and the db.t2.micro DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with default, and it must use the default subnet group.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowCreateDBInstanceOnly",  
            "Effect": "Allow",  
            "Action": [  
                "rds>CreateDBInstance"  
            ],  
            "Resource": [  
                "arn:aws:rds::123456789012:db:test*",  
                "arn:aws:rds::123456789012:og:default*",  
                "arn:aws:rds::123456789012:subnetgroup:default"  
            ]  
        }  
    ]  
}
```

```
        "arn:aws:rds:*:123456789012:pg:default*",
        "arn:aws:rds:*:123456789012:subgrp:default"
    ],
    "Condition": {
        "StringEquals": {
            "rds:DatabaseEngine": "mysql",
            "rds:DatabaseClass": "db.t2.micro"
        }
    }
}
```

The policy includes a single statement that specifies the following permissions for the IAM user:

- The policy allows the IAM user to create a DB instance using the [CreateDBInstance](#) API operation (this also applies to the [create-db-instance](#) AWS CLI command and the AWS Management Console).
- The `Resource` element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resources Name (ARN). This ARN includes the name of the service that the resource belongs to (`rds`), the AWS Region (\* indicates any region in this example), the user account number (123456789012 is the user ID in this example), and the type of resource. For more information about creating ARNs, see [Working with Amazon Resource Names \(ARNs\) in Amazon RDS \(p. 360\)](#).

The `Resource` element in the example specifies the following policy constraints on resources for the user:

- The DB instance identifier for the new DB instance must begin with `test` (for example, `testCustomerData1`, `test-region2-data`).
- The option group for the new DB instance must begin with `default`.
- The DB parameter group for the new DB instance must begin with `default`.
- The subnet group for the new DB instance must be the `default` subnet group.
- The `Condition` element specifies that the DB engine must be MySQL and the DB instance class must be `db.t2.micro`. The `Condition` element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the `Condition` element. For more information about specifying conditions, see [Policy condition keys for Aurora \(p. 1660\)](#). This example specifies the `rds:DatabaseEngine` and `rds:DatabaseClass` conditions. For information about the valid condition values for `rds:DatabaseEngine`, see the list under the `Engine` parameter in [CreateDBInstance](#). For information about the valid condition values for `rds:DatabaseClass`, see [Supported DB engines for DB instance classes \(p. 57\)](#).

The policy doesn't specify the `Principal` element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Aurora actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

## Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon Aurora resources for their AWS account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the `AmazonRDSReadOnlyAccess` managed policy to the user, as described in [Managing access using policies \(p. 1655\)](#).

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the Amazon RDS API.

The following policy grants full access to all Amazon Aurora resources for the root AWS account:

```
AmazonRDSFullAccess
```

## Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with `Describe`. These actions show information about an RDS resource, such as a DB instance. The wildcard character (\*) in the `Resource` element indicates that the actions are allowed for all Amazon Aurora resources owned by the account.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRDSDescribe",
            "Effect": "Allow",
            "Action": "rds:Describe*",
            "Resource": "*"
        }
    ]
}
```

## Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the `mydbpg` DB parameter group and the `mydbsubnetgroup` DB subnet group.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "rds>CreateDBInstance",
            "Resource": [
                "arn:aws:rds::*:pg:mydbpg",
                "arn:aws:rds::*:subgrp:mydbsubnetgroup"
            ]
        }
    ]
}
```

## Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Aurora resources based on tags. The following policy allows permission to perform the `ModifyDBInstance` and `CreateDBSnapshot` API operations on DB instances with either the `stage` tag set to `development` or `test`.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowDevTestCreate",
            "Effect": "Allow",
            "Action": [
                "rds:ModifyDBInstance",
                "rds>CreateDBSnapshot"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "rds:db-tag/stage": [
                        "development",
                        "test"
                    ]
                }
            }
        }
    ]
}
```

## Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyDelete1",
            "Effect": "Deny",
            "Action": "rds>DeleteDBInstance",
            "Resource": "arn:aws:rds:us-west-2:123456789012:db:my-mysql-instance"
        }
    ]
}
```

## Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": "rds:*",
            "Resource": "arn:aws:rds:us-east-1:123456789012:db:mydb"
        }
    ]
}
```

## Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon Aurora IAM permissions policies.

## Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The Condition element indicates the requirement that the database engine is MySQL.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowMySQLCreate",  
            "Effect": "Allow",  
            "Action": "rds>CreateDBInstance",  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "rds:DatabaseEngine": "mysql"  
                },  
                "Bool": {  
                    "rds:MultiAz": false  
                }  
            }  
        }  
    ]  
}
```

## Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes `r3.8xlarge` and `m4.10xlarge`, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities do not accidentally get permission that you never want to grant.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DenyLargeCreate",  
            "Effect": "Deny",  
            "Action": "rds>CreateDBInstance",  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "rds:DatabaseClass": [  
                        "db.r3.8xlarge",  
                        "db.m4.10xlarge"  
                    ]  
                }  
            }  
        },  
        {  
            "Sid": "DenyPIOPSCreate",  
            "Effect": "Deny",  
            "Action": "rds>CreateDBInstance",  
            "Resource": "*",  
            "Condition": {  
                "StringEquals": {  
                    "rds:ProvisionedIOPS": "true"  
                }  
            }  
        }  
    ]  
}
```

```
        "NumericNotEquals": {
            "rds:Piops": "0"
        }
    }
}
```

**Example 3: Limit the set of tag keys and values that can be used to tag a resource**

The following policy uses an RDS condition key and allows the addition of a tag with the key stage to be added to a resource with the values test, qa, and production.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "rds:AddTagsToResource",  
                "rds:RemoveTagsFromResource"  
            ],  
            "Resource": "*",  
            "Condition": {  
                "streq": {  
                    "rds:req-tag/stage": [  
                        "test",  
                        "qa",  
                        "production"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

## Specifying conditions: Using custom tags

Amazon Aurora supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named `environment` to your DB instances with values such as `beta`, `staging`, `production`, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the `environment` tag value.

## Note

**Note** Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a Condition element.

RDS tag identifier	Applies to
db-tag	DB instances, including read replicas
snapshot-tag	DB snapshots
ri-tag	Reserved DB instances
og-tag	DB option groups
pg-tag	DB parameter groups

RDS tag identifier	Applies to
subgrp-tag	DB subnet groups
es-tag	Event subscriptions
cluster-tag	DB clusters
cluster-pg-tag	DB cluster parameter groups
cluster-snapshot-tag	DB cluster snapshots

The syntax for a custom tag condition is as follows:

```
"Condition": {"StringEquals": {"rds:rds-tag-identifier/tag-name": ["value"]}}
```

For example, the following Condition element applies to DB instances with a tag named `environment` and a tag value of `production`.

```
"Condition": {"StringEquals": {"rds:db-tag/environment": ["production"]}}
```

For information about creating tags, see [Tagging Amazon RDS resources \(p. 352\)](#).

#### Important

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the `AddTagsToResource` and `RemoveTagsFromResource` actions. For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyTagUpdates",
            "Effect": "Deny",
            "Action": [
                "rds:AddTagsToResource",
                "rds:RemoveTagsFromResource"
            ],
            "Resource": "*"
        }
    ]
}
```

To see a list of Aurora actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

### Example policies: Using custom tags

Following are examples of how you can use custom tags in Amazon Aurora IAM permissions policies. For more information about adding tags to an Amazon Aurora resource, see [Working with Amazon Resource Names \(ARNs\) in Amazon RDS \(p. 360\)](#).

#### Note

All examples use the us-west-2 region and contain fictitious account IDs.

#### Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the `ModifyDBInstance` and `CreateDBSnapshot` API operations on DB instances with either the `stage` tag set to `development` or `test`.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowDevTestCreate",
            "Effect": "Allow",
            "Action": [
                "rds:ModifyDBInstance",
                "rds>CreateDBSnapshot"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "rds:db-tag/stage": [
                        "development",
                        "test"
                    ]
                }
            }
        ]
    ]
}
```

#### Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use Deny are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyProductionCreate",
            "Effect": "Deny",
            "Action": "rds:CreateDBInstance",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "rds:pg-tag/usage": "prod"
                }
            }
        }
    ]
}
```

#### Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to `AddTagsToResource` or `RemoveTagsFromResource`) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called `stage` equal to `devo` or that has no tag called `stage`.

The Resource line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon Aurora resources, see [Working with Amazon Resource Names \(ARNs\) in Amazon RDS \(p. 360\)](#).

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowFullDevAccessNoTags",  
            "Effect": "Allow",  
            "NotAction": [  
                "rds:AddTagsToResource",  
                "rds:RemoveTagsFromResource"  
            ],  
            "Resource": "arn:aws:rds:*:123456789012:db:${aws:username}*",  
            "Condition": {  
                "StringEqualsIfExists": {  
                    "rds:db-tag/stage": "devo"  
                }  
            }  
        }  
    ]  
}
```

## AWS managed policies for Amazon RDS

To add permissions to users, groups, and roles, it's easier to use AWS managed policies than to write policies yourself. It takes time and expertise to [create IAM customer managed policies](#) that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see [AWS managed policies](#) in the *IAM User Guide*.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an AWS managed policy, so policy updates don't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the `ReadOnlyAccess` AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see [AWS managed policies for job functions](#) in the *IAM User Guide*.

## AWS managed policy: AmazonRDSReadOnlyAccess

This policy allows read-only access to Amazon RDS through the AWS Management Console.

### Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- `cloudwatch` – Allows principals to get Amazon CloudWatch metric statistics.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "rds:Describe*",  
                "rds>ListTagsForResource",  
                "ec2:DescribeAccountAttributes",  
                "ec2:DescribeAvailabilityZones",  
                "ec2:DescribeInternetGateways",  
                "logs:GetLogEvents",  
                "logs:DescribeLogStreams",  
                "logs:CreateLogStream",  
                "logs:PutLogEvents"  
            ],  
            "Effect": "Allow",  
            "Resource": "*"  
        }  
    ]  
}
```

```
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSubnets",
        "ec2:DescribeVpcAttribute",
        "ec2:DescribeVpcs"
    ],
    "Effect": "Allow",
    "Resource": "*"
},
{
    "Action": [
        "cloudwatch:GetMetricStatistics",
        "logs:DescribeLogStreams",
        "logs:GetLogEvents"
    ],
    "Effect": "Allow",
    "Resource": "*"
}
]
```

## AWS managed policy: AmazonRDSFullAccess

This policy provides full access to Amazon RDS through the AWS Management Console.

### Permissions details

This policy includes the following permissions:

- **rds** – Allows principals full access to Amazon RDS.
- **application-autoscaling** – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- **cloudwatch** – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- **ec2** – Allows principals to describe Availability Zones and networking resources.
- **logs** – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- **outposts** – Allows principals to get AWS Outposts instance types.
- **pi** – Allows principals to get Performance Insights metrics.
- **sns** – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "rds:*",
                "application-autoscaling>DeleteScalingPolicy",
                "application-autoscaling>DeregisterScalableTarget",

```

## AWS managed policy: AmazonRDSDDataFullAccess

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific AWS account. This policy allows the AWS account to get the value of a secret from AWS Secrets Manager.

You can attach the [AmazonRDSDDataFullAccess](#) policy to your IAM identities.

### Permissions details

This policy includes the following permissions:

- **dbqms** – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.
- **rds-data** – Allows principals to run SQL statements on Aurora Serverless databases.
- **secretsmanager** – Allows principals to get the value of a secret from AWS Secrets Manager.

{

```

    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SecretsManagerDbCredentialsAccess",
            "Effect": "Allow",
            "Action": [

## AWS managed policy: AmazonRDSEnhancedMonitoringRole

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

### Permissions details

This policy includes the following permissions:

- logs – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogGroups",
            "Effect": "Allow",

```

```

        "Action": [
            "logs:CreateLogGroup",
            "logs:PutRetentionPolicy"
        ],
        "Resource": [
            "arn:aws:logs:*:log-group:RDS*"
        ]
    },
    {
        "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogStreams",
        "Effect": "Allow",
        "Action": [
            "logs:CreateLogStream",
            "logs:PutLogEvents",
            "logs:DescribeLogStreams",
            "logs:GetLogEvents"
        ],
        "Resource": [
            "arn:aws:logs:*:log-group:RDS*:log-stream:*
        ]
    }
]
}

```

## AWS managed policy: [AmazonRDSPerformanceInsightsReadOnly](#)

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

### Permissions details

This policy includes the following permissions:

- **rds** – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- **pi** – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "rds:DescribeDBInstances",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "rds:DescribeDBClusters",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "pi:DescribeDimensionKeys",
            "Resource": "arn:aws:pi:metrics/rds/*"
        },
        {
            "Effect": "Allow",
            "Action": "pi:GetDimensionKeyDetails",
            "Resource": "arn:aws:pi:metrics/rds/*"
        },
    ]
}

```

```
{  
    "Effect": "Allow",  
    "Action": "pi:GetResourceMetadata",  
    "Resource": "arn:aws:pi:*.*:metrics/rds/*"  
},  
{  
    "Effect": "Allow",  
    "Action": "pi:GetResourceMetrics",  
    "Resource": "arn:aws:pi:*.*:metrics/rds/*"  
},  
{  
    "Effect": "Allow",  
    "Action": "pi>ListAvailableResourceDimensions",  
    "Resource": "arn:aws:pi:*.*:metrics/rds/*"  
},  
{  
    "Effect": "Allow",  
    "Action": "pi>ListAvailableResourceMetrics",  
    "Resource": "arn:aws:pi:*.*:metrics/rds/*"  
}  
]  
}
```

## AWS managed policy: AmazonRDSDirectoryServiceAccess

This policy allows Amazon RDS to make calls to the AWS Directory Service.

### Permissions details

This policy includes the following permissions:

- **ds** – Allows principals to describe AWS Directory Service directories and control authorization to AWS Directory Service directories.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "ds:DescribeDirectories",  
                "ds:AuthorizeApplication",  
                "ds:UnauthorizeApplication",  
                "ds:GetAuthorizedApplicationDetails"  
            ],  
            "Effect": "Allow",  
            "Resource": "*"  
        }  
    ]  
}
```

## AWS managed policy: AmazonRDSServiceRolePolicy

You can't attach the `AmazonRDSServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see [Service-linked role permissions for Amazon Aurora \(p. 1724\)](#).

## Amazon RDS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS [Document history](#) page.

## Preventing cross-service confused deputy problems

The *confused deputy problem* is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, AWS provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see [The confused deputy problem](#) in the *IAM User Guide*.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies.

In some cases, the `aws:SourceArn` value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the `aws:SourceArn` value contains the account ID. In these cases, make sure that the `aws:SourceAccount` value and the account in the `aws:SourceArn` use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use `aws:SourceArn`. If you want to allow any resource in the specified AWS account to be associated with the cross-service use, use `aws:SourceAccount`.

Make sure that the value of `aws:SourceArn` is an ARN for an Amazon RDS resource type. For more information, see [Working with Amazon Resource Names \(ARNs\) in Amazon RDS \(p. 360\)](#).

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the `aws:SourceArn` global context condition key with wildcards (\*) for the unknown portions of the ARN. An example is `arn:aws:rds:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

```
{  
    "Version": "2012-10-17",  
    "Statement": {  
        "Sid": "ConfusedDeputyPreventionExamplePolicy",  
        "Effect": "Allow",  
        "Principal": {  
            "Service": "rds.amazonaws.com"  
        },  
        "Action": "sts:AssumeRole",  
        "Condition": {  
            "ArnLike": {  
                "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"  
            },  
            "StringEquals": {  
                "aws:SourceAccount": "123456789012"  
            }  
        }  
    }  
}
```

For more examples of policies that use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys, see the following sections:

- [Granting permissions to publish notifications to an Amazon SNS topic \(p. 577\)](#)
- [Setting up access to an Amazon S3 bucket \(p. 1233\) \(PostgreSQL import\)](#)
- [Setting up access to an Amazon S3 bucket \(p. 1246\) \(PostgreSQL export\)](#)

## IAM database authentication

You can authenticate to your DB cluster using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with Aurora MySQL, and Aurora PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

An *authentication token* is a unique string of characters that Amazon Aurora generates on request. Authentication tokens are generated using AWS Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon Aurora, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB cluster.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when your applications create fewer than 200 connections per second, and you don't want to manage usernames and passwords directly in your application code.

The AWS JDBC Driver for MySQL supports IAM database authentication. For more information, see [AWS IAM Database Authentication](#) in the AWS JDBC Driver for MySQL GitHub repository.

### Topics

- [Region and version availability \(p. 1683\)](#)
- [CLI and SDK support \(p. 1684\)](#)
- [Limitations for IAM database authentication \(p. 1684\)](#)
- [Recommendations for IAM database authentication \(p. 1684\)](#)
- [Enabling and disabling IAM database authentication \(p. 1685\)](#)
- [Creating and using an IAM policy for IAM database access \(p. 1686\)](#)
- [Creating a database account using IAM authentication \(p. 1689\)](#)
- [Connecting to your DB cluster using IAM authentication \(p. 1690\)](#)

## Region and version availability

IAM database authentication is available in all Regions.

IAM database authentication is available for the following database engines:

- **Aurora MySQL**
  - Aurora MySQL version 3, all minor versions
  - Aurora MySQL version 2, all minor versions
  - Aurora MySQL version 1.10 and higher 1.1 minor versions
- **Aurora PostgreSQL**
  - All Aurora PostgreSQL 14, 13, and 12 versions

- Aurora PostgreSQL 11.6 and higher 11 versions
- Aurora PostgreSQL 10.11 and higher 10 versions
- Aurora PostgreSQL 9.6.16 and higher 9.6 versions

For more information, see [Amazon Aurora PostgreSQL releases and engine versions \(p. 1414\)](#).

For Aurora MySQL, all supported DB instance classes support IAM database authentication, except for db.t2.small and db.t3.small. For information about the supported DB instance classes, see [Supported DB engines for DB instance classes \(p. 57\)](#).

## CLI and SDK support

IAM database authentication is available for the [AWS CLI](#) and for the following language-specific AWS SDKs:

- [AWS SDK for .NET](#)
- [AWS SDK for C++](#)
- [AWS SDK for Go](#)
- [AWS SDK for Java](#)
- [AWS SDK for JavaScript](#)
- [AWS SDK for PHP](#)
- [AWS SDK for Python \(Boto3\)](#)
- [AWS SDK for Ruby](#)

## Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

- The maximum number of connections per second for your DB cluster might be limited depending on its DB instance class and your workload.
- Currently, IAM database authentication doesn't support all global condition context keys.

For more information about global condition context keys, see [AWS global condition context keys in the IAM User Guide](#).

- Currently, IAM database authentication isn't supported for CNAMEs.
- For PostgreSQL, if the IAM role (`rds_iam`) is added to a user (including the RDS the master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.

## Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

- Use IAM database authentication as a mechanism for temporary, personal access to databases.
- Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

The database engines that work with Amazon Aurora don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB cluster. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling.

## Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB clusters. You can enable or disable IAM database authentication using the AWS Management Console, AWS CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB cluster with IAM database authentication enabled, see [Creating an Amazon Aurora DB cluster \(p. 127\)](#).
- To modify a DB cluster to enable IAM database authentication, see [Modifying an Amazon Aurora DB cluster \(p. 248\)](#).
- To restore a DB cluster from a snapshot with IAM database authentication enabled, see [Restoring from a DB cluster snapshot \(p. 375\)](#).
- To restore a DB cluster to a point in time with IAM database authentication enabled, see [Restoring a DB cluster to a specified time \(p. 415\)](#).

### Console

Each creation or modification workflow has a **Database authentication** section, where you can enable or disable IAM database authentication. In that section, choose **Password and IAM database authentication** to enable IAM database authentication.

#### To enable or disable IAM database authentication for an existing DB cluster

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster that you want to modify.

##### Note

You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in [Region and version availability \(p. 1683\)](#).

4. Choose **Modify**.
5. In the **Database authentication** section, choose **Password and IAM database authentication** to enable IAM database authentication.
6. Choose **Continue**.
7. To apply the changes immediately, choose **Immediately** in the **Scheduling of modifications** section.
8. Choose **Modify cluster**.

### AWS CLI

To create a new DB cluster with IAM authentication by using the AWS CLI, use the `create-db-cluster` command. Specify the `--enable-iam-database-authentication` option.

To update an existing DB cluster to have or not have IAM authentication, use the AWS CLI command `modify-db-cluster`. Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

##### Note

You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in [Region and version availability \(p. 1683\)](#).

By default, Aurora performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

If you are restoring a DB cluster, use one of the following AWS CLI commands:

- [restore-db-cluster-to-point-in-time](#)
- [restore-db-cluster-from-db-snapshot](#)

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

## RDS API

To create a new DB instance with IAM authentication by using the API, use the API operation [CreateDBCluster](#). Set the `EnableIAMDatabaseAuthentication` parameter to `true`.

To update an existing DB cluster to have IAM authentication, use the API operation [ModifyDBCluster](#). Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

### Note

You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in [Region and version availability \(p. 1683\)](#).

If you are restoring a DB cluster, use one of the following API operations:

- [RestoreDBClusterFromSnapshot](#)
- [RestoreDBClusterToPointInTime](#)

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

## Creating and using an IAM policy for IAM database access

To allow an IAM user or role to connect to your DB cluster, you must create an IAM policy. After that, you attach the policy to an IAM user or role.

### Note

To learn more about IAM policies, see [Identity and access management for Amazon Aurora \(p. 1653\)](#).

The following example policy allows an IAM user to connect to a DB cluster using IAM database authentication.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "rds-db:connect"  
            ],  
            "Resource": [  
                "arn:aws:rds-db:us-east-2:1234567890:dbuser:cluster-ABCDEFGHIJKLM01234/db_user"  
            ]  
        }  
    ]  
}
```

### Important

An IAM administrator user can access DB clusters without explicit permissions in an IAM policy. The example in [Create an IAM user \(p. 87\)](#) creates an IAM administrator user. If you want to restrict administrator access to DB clusters, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

### Note

Don't confuse the `rds-db:` prefix with other RDS API operation prefixes that begin with `rds:`. You use the `rds-db:` prefix and the `rds-db:connect` action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- **Effect** – Specify `Allow` to grant access to the DB cluster. If you don't explicitly allow access, then access is denied by default.
- **Action** – Specify `rds-db:connect` to allow connections to the DB cluster.
- **Resource** – Specify an Amazon Resource Name (ARN) that describes one database account in one DB cluster. The ARN format is as follows.

```
arn:aws:rds-db:region:account-id:dbuser:DbClusterResourceId/db-user-name
```

In this format, replace the following:

- **region** is the AWS Region for the DB cluster. In the example policy, the AWS Region is `us-east-2`.
- **account-id** is the AWS account number for the DB cluster. In the example policy, the account number is `1234567890`.
- **DbClusterResourceId** is the identifier for the DB cluster. This identifier is unique to an AWS Region and never changes. In the example policy, the identifier is `cluster-ABCDEFGHIJKL01234`.

To find a DB cluster resource ID in the AWS Management Console for Amazon Aurora, choose the DB cluster to see its details. Then choose the **Configuration** tab. The **Resource ID** is shown in the **Configuration** section.

Alternatively, you can use the AWS CLI command to list the identifiers and resource IDs for all of your DB cluster in the current AWS Region, as shown following.

```
aws rds describe-db-clusters --query "DBClusters[*].  
[DBClusterIdentifier,DbClusterResourceId]"
```

### Note

If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as `prx-ABCDEFGHIJKL01234`. For information about using IAM database authentication with RDS Proxy, see [Connecting to a proxy using IAM authentication \(p. 1447\)](#).

- **db-user-name** is the name of the database account to associate with IAM authentication. In the example policy, the database account is `db_user`.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB cluster.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws:rds-db:us-east-2:123456789012:dbuser:cluster-ABCDEFGHIJKL01234/jane_doe",
                "arn:aws:rds-db:us-east-2:123456789012:dbuser:cluster-ABCDEFGHIJKL01234/mary_roe"
            ]
        }
    ]
}
```

The following policy uses the "\*" character to match all DB clusters and database accounts for a particular AWS account and AWS Region.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws:rds-db:us-east-2:1234567890:dbuser:*/**"
            ]
        }
    ]
}
```

The following policy matches all of the DB clusters for a particular AWS account and AWS Region. However, the policy only grants access to DB clusters that have a `jane_doe` database account.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws:rds-db:us-east-2:123456789012:dbuser:*/jane_doe"
            ]
        }
    ]
}
```

The IAM user or role has access to only those databases that the database user does. For example, suppose that your DB cluster has a database named `dev`, and another database named `test`. If the database user `jane_doe` has access only to `dev`, any IAM users or roles that access that DB cluster with

the `jane_doe` user also have access only to `dev`. This access restriction is also true for other database objects, such as tables, views, and so on.

An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions. For examples of policies, see [Identity-based policy examples for Amazon Aurora \(p. 1662\)](#).

## Attaching an IAM policy to an IAM user or role

After you create an IAM policy to allow database authentication, you need to attach the policy to an IAM user or role. For a tutorial on this topic, see [Create and attach your first customer managed policy](#) in the *IAM User Guide*.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have an IAM user with an attached policy that can make use of the `rds-db:connect` action.

**Note**

You can map multiple IAM users or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.

```
arn:aws:rds-db:us-east-2:123456789012:dbuser:cluster-12ABC34DEFG5HIJ6KLMNOP78QR/jane_doe
```

If you attach the policy to IAM users *Jane*, *Bob*, and *Diego*, then each of those users can connect to the specified DB cluster using the `jane_doe` database account.

## Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove an IAM user that is mapped to a database account, you should also remove the database account with the `DROP USER` statement.

**Note**

The user name used for IAM authentication must match the case of the user name in the database.

**Topics**

- [Using IAM authentication with Aurora MySQL \(p. 1689\)](#)
- [Using IAM authentication with Aurora PostgreSQL \(p. 1690\)](#)

## Using IAM authentication with Aurora MySQL

With Aurora MySQL, authentication is handled by `AWSAuthenticationPlugin`—an AWS-provided plugin that works seamlessly with IAM to authenticate your IAM users. Connect to the DB cluster and issue the `CREATE USER` statement, as shown in the following example.

```
CREATE USER jane_doe IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The `IDENTIFIED WITH` clause allows Aurora MySQL to use the `AWSAuthenticationPlugin` to authenticate the database account (`jane_doe`). The `AS 'RDS'` clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for

IAM database access. For more information, see [Creating and using an IAM policy for IAM database access \(p. 1686\)](#).

**Note**

If you see the following message, it means that the AWS-provided plugin is not available for the current DB cluster.

ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded  
To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB cluster. For more information, see [Region and version availability \(p. 1683\)](#) and [Enabling and disabling IAM database authentication \(p. 1685\)](#).

After you create an account using `AWSAuthenticationPlugin`, you manage it in the same way as other database accounts. For example, you can modify account privileges with `GRANT` and `REVOKE` statements, or modify various account attributes with the `ALTER USER` statement.

## Using IAM authentication with Aurora PostgreSQL

To use IAM authentication with Aurora PostgreSQL, connect to the DB cluster, create database users, and then grant them the `rds_iam` role as shown in the following example.

```
CREATE USER db_userx;
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see [Creating and using an IAM policy for IAM database access \(p. 1686\)](#).

Note that a PostgreSQL database user can use either IAM or Kerberos authentication but not both, so this user can't also have the `rds_ad` role. This also applies to nested memberships. For more information, see [Step 7: Create Kerberos authentication PostgreSQL logins \(p. 1045\)](#).

## Connecting to your DB cluster using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB cluster. An *authentication token* is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using AWS signature version 4. (For more information, see [Signature Version 4 signing process](#) in the *AWS General Reference*.) The AWS CLI and an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (`Boto3`), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon Aurora from another AWS service, such as AWS Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an AWS SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Aurora DB cluster. Following, you can find out how to do this using either a command line tool or an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (`Boto3`).

For more information, see the following blog posts:

- [Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL](#)
- [Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL](#)

## Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication \(p. 1685\)](#)
- [Creating and using an IAM policy for IAM database access \(p. 1686\)](#)
- [Creating a database account using IAM authentication \(p. 1689\)](#)

#### Topics

- [Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and mysql client \(p. 1691\)](#)
- [Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and psql client \(p. 1693\)](#)
- [Connecting to your DB cluster using IAM authentication and the AWS SDK for .NET \(p. 1694\)](#)
- [Connecting to your DB cluster using IAM authentication and the AWS SDK for Go \(p. 1697\)](#)

- [Connecting to your DB cluster using IAM authentication and the AWS SDK for Python \(Boto3\) \(p. 1708\)](#)

## Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and mysql client

You can connect from the command line to an Aurora DB cluster with the AWS CLI and `mysql` command line tool as described following.

#### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication \(p. 1685\)](#)
- [Creating and using an IAM policy for IAM database access \(p. 1686\)](#)
- [Creating a database account using IAM authentication \(p. 1689\)](#)

#### Note

For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post [Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL](#).

#### Topics

- [Generating an IAM authentication token \(p. 1691\)](#)
- [Connecting to a DB cluster \(p. 1692\)](#)

## Generating an IAM authentication token

The following example shows how to get a signed authentication token using the AWS CLI.

```
aws rds generate-db-auth-token \
--hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \
--port 3306 \
--region us-west-2 \
--username jane_doe
```

In the example, the parameters are as follows:

- **--hostname** – The host name of the DB cluster that you want to access
- **--port** – The port number used for connecting to your DB cluster
- **--region** – The AWS Region where the DB cluster is running
- **--username** – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

## Connecting to a DB cluster

The general format for connecting is shown following.

```
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- **--host** – The host name of the DB cluster that you want to access
- **--port** – The port number used for connecting to your DB cluster
- **--ssl-ca** – The full path to the SSL certificate file that contains the public key

For more information, see [Using SSL/TLS with Aurora MySQL DB clusters \(p. 683\)](#).

To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).

- **--enable-cleartext-plugin** – A value that specifies that `AWSAuthenticationPlugin` must be used for this connection

If you are using a MariaDB client, the `--enable-cleartext-plugin` option isn't required.

- **--user** – The database account that you want to access
- **--password** – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```
RDSHOST="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"  
TOKEN=$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-west-2  
--username jane_doe)  
  
mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using `AWSAuthenticationPlugin`, the connection is secured using SSL. To verify this, type the following at the `mysql>` command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+-----+-----+
```

Variable_name	Value
...	...
Ssl_cipher	AES256-SHA
...	...
Ssl_version	TLSv1.1
...	...

## Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and psql client

You can connect from the command line to an Aurora PostgreSQL DB cluster with the AWS CLI and psql command line tool as described following.

### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication \(p. 1685\)](#)
- [Creating and using an IAM policy for IAM database access \(p. 1686\)](#)
- [Creating a database account using IAM authentication \(p. 1689\)](#)

### Note

For information about connecting to your database using pgAdmin with IAM authentication, see the blog post [Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL](#).

### Topics

- [Generating an IAM authentication token \(p. 1693\)](#)
- [Connecting to an Aurora PostgreSQL cluster \(p. 1694\)](#)

## Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the AWS CLI to get a signed authentication token using the generate-db-auth-token command, and store it in a PGASSWORD environment variable.

```
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD=$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"
```

In the example, the parameters to the generate-db-auth-token command are as follows:

- **--hostname** – The host name of the DB cluster (cluster endpoint) that you want to access
- **--port** – The port number used for connecting to your DB cluster
- **--region** – The AWS Region where the DB cluster is running

- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com:5432/?  
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

## Connecting to an Aurora PostgreSQL cluster

The general format for using `psql` to connect is shown following.

```
psql "host=hostName port=portNumber sslmode=verify-full  
sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName password=authToken"
```

The parameters are as follows:

- `host` – The host name of the DB cluster (cluster endpoint) that you want to access
- `port` – The port number used for connecting to your DB cluster
- `sslmode` – The SSL mode to use

When you use `sslmode=verify-full`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- `sslrootcert` – The full path to the SSL certificate file that contains the public key

For more information, see [Securing Aurora PostgreSQL data with SSL/TLS \(p. 1029\)](#).

To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).

- `dbname` – The database that you want to access
- `user` – The database account that you want to access
- `password` – A signed IAM authentication token

The following example shows using `psql` to connect. In the example, `psql` uses the environment variable `RDSHOST` for the host and the environment variable `PGPASSWORD` for the generated token. Also, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"  
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --  
region us-west-2 --username jane_doe)"  
  
psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-bundle.pem  
dbname=DBName user=jane_doe password=$PGPASSWORD"
```

## Connecting to your DB cluster using IAM authentication and the AWS SDK for .NET

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for .NET as described following.

### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication \(p. 1685\)](#)
- [Creating and using an IAM policy for IAM database access \(p. 1686\)](#)

- [Creating a database account using IAM authentication \(p. 1689\)](#)

## Examples

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the [AWS SDK for .NET](#), found on the AWS site. The `AWSSDK.Core` and the `AWSSDK.RDS` packages are required. To connect to a DB cluster, use the .NET database connector for the DB engine, such as `MySQLConnector` for MariaDB or MySQL, or `Npgsql` for PostgreSQL.

This code connects to an Aurora MySQL DB cluster.

Modify the values of the following variables as needed:

- `server` – The endpoint of the DB cluster that you want to access
- `user` – The database account that you want to access
- `database` – The database that you want to access
- `port` – The port number used for connecting to your DB cluster
- `SslMode` – The SSL mode to use

When you use `SslMode=Required`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- `SslCa` – The full path to the SSL certificate for Amazon Aurora

To download a certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).

```
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd =
Amazon.RDS.Util.RDSSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1,
"mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
            // for debug only Console.WriteLine("{0}\n", pwd); //this verifies the token is
generated

            MySqlConnection conn = new
MySqlConnection($"server=mysqlcluster.cluster-123456789012.us-
east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;SslCa=fu
conn.Open();

            // Define a query
            MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

            // Execute a query
            MySqlDataReader mysqlDataRdr = sampleCommand.ExecuteReader();

            // Read all rows and output the first column in each row
            while (mysqlDataRdr.Read())
                Console.WriteLine(mysqlDataRdr[0]);
```

```
        mysqlDataRdr.Close();
        // Close connection
        conn.Close();
    }
}
```

This code connects to an Aurora PostgreSQL DB cluster.

Modify the values of the following variables as needed:

- **Server** – The endpoint of the DB cluster that you want to access
  - **User ID** – The database account that you want to access
  - **Database** – The database that you want to access
  - **Port** – The port number used for connecting to your DB cluster
  - **SSL Mode** – The SSL mode to use

When you use `SSL Mode=Required`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- Root Certificate – The full path to the SSL certificate for Amazon Aurora

To download a certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).

```
using System;
using Npgsql;
using Amazon.RDS.Util;

namespace ConsoleApp1
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd =
RDSAAuthGenerator.GenerateAuthToken("postgresmycluster.cluster-123456789012.us-
east-1.rds.amazonaws.com", 5432, "jane_doe");
// for debug only Console.WriteLine("{0}\n", pwd); //this verifies the token is generated

            NpgsqlConnection conn = new
NpgsqlConnection($"Server=postgresmycluster.cluster-123456789012.us-
east-1.rds.amazonaws.com;User Id=jane_doe;Password={pwd};Database=mydb;SSL
Mode=Require;Root Certificate=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
            NpgsqlCommand cmd = new NpgsqlCommand("select count(*) FROM pg_user"
conn);

            // Execute a query
            NpgsqlDataReader dr = cmd.ExecuteReader();

            // Read all rows and output the first column in each row
            while (dr.Read())
                Console.WriteLine("{0}\n", dr[0]);

            // Close connection
            conn.Close();
        }
    }
}
```

## Connecting to your DB cluster using IAM authentication and the AWS SDK for Go

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Go as described following.

### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication \(p. 1685\)](#)
- [Creating and using an IAM policy for IAM database access \(p. 1686\)](#)
- [Creating a database account using IAM authentication \(p. 1689\)](#)

### Examples

To run these code examples, you need the [AWS SDK for Go](#), found on the AWS site.

Modify the values of the following variables as needed:

- `dbName` – The database that you want to access
- `dbUser` – The database account that you want to access
- `dbHost` – The endpoint of the DB cluster that you want to access
- `dbPort` – The port number used for connecting to your DB cluster
- `region` – The AWS Region where the DB cluster is running

In addition, make sure the imported libraries in the sample code exist on your system.

#### Important

The examples in this section use the following code to provide credentials that access a database from a local environment:

```
creds := credentials.NewEnvCredentials()
```

If you are accessing a database from an AWS service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

```
sess := session.Must(session.NewSession())
creds := sess.Config.Credentials
```

If you make this change, make sure you add the following import:  
`"github.com/aws/aws-sdk-go/aws/session"`

### Topics

- [Connecting using IAM authentication and the AWS SDK for Go V2 \(p. 1697\)](#)
- [Connecting using IAM authentication and the AWS SDK for Go V1. \(p. 1699\)](#)

## Connecting using IAM authentication and the AWS SDK for Go V2

You can connect to a DB cluster using IAM authentication and the AWS SDK for Go V2.

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

This code connects to an Aurora MySQL DB cluster.

```
package main

import (
    "context"
    "database/sql"
    "fmt"
```

```

    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    _ "github.com/go-sql-driver/mysql"
)

func main() {

    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 3306
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
        dbUser, authenticationToken, dbEndpoint, dbName,
    )

    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}

```

This code connects to an Aurora PostgreSQL DB cluster.

```

package main

import (
    "context"
    "database/sql"
    "fmt"

    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    _ "github.com/lib/pq"
)

func main() {

    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "postgresmycluster.cluster-123456789012.us-
east-1.rds.amazonaws.com"
    var dbPort int = 5432
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"
}

```

```

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    panic("configuration error: " + err.Error())
}

authenticationToken, err := auth.BuildAuthToken(
    context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
if err != nil {
    panic("failed to create authentication token: " + err.Error())
}

dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
    dbHost, dbPort, dbUser, authenticationToken, dbName,
)
db, err := sql.Open("postgres", dsn)
if err != nil {
    panic(err)
}

err = db.Ping()
if err != nil {
    panic(err)
}
}
}

```

### Connecting using IAM authentication and the AWS SDK for Go V1.

You can connect to a DB cluster using IAM authentication and the AWS SDK for Go V1

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

This code connects to an Aurora MySQL DB cluster.

```

package main

import (
    "database/sql"
    "fmt"
    "log"

    "github.com/aws/aws-sdk-go/aws/credentials"
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
    _ "github.com/go-sql-driver/mysql"
)

func main() {
    dbName := "app"
    dbUser := "jane_doe"
    dbHost := "mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
    dbPort := 3306
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
    region := "us-east-1"

    creds := credentials.NewEnvCredentials()
    authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
    if err != nil {
        panic(err)
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowClearTextPasswords=true",
        dbUser, authToken, dbEndpoint, dbName,
    )
}

```

```
db, err := sql.Open("mysql", dsn)
if err != nil {
    panic(err)
}

err = db.Ping()
if err != nil {
    panic(err)
}
}
```

This code connects to an Aurora PostgreSQL DB cluster.

```
package main

import (
    "database/sql"
    "fmt"

    "github.com/aws/aws-sdk-go/aws/credentials"
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
    _ "github.com/lib/pq"
)

func main() {
    dbName := "app"
    dbUser := "jane_doe"
    dbHost := "postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
    dbPort := 5432
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
    region := "us-east-1"

    creds := credentials.NewEnvCredentials()
    authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
    if err != nil {
        panic(err)
    }

    dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
        dbHost, dbPort, dbUser, authToken, dbName,
    )

    db, err := sql.Open("postgres", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

## Connecting to your DB cluster using IAM authentication and the AWS SDK for Java

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Java as described following.

### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication \(p. 1685\)](#)
- [Creating and using an IAM policy for IAM database access \(p. 1686\)](#)
- [Creating a database account using IAM authentication \(p. 1689\)](#)
- [Set up the AWS SDK for Java](#)

## Topics

- [Generating an IAM authentication token \(p. 1701\)](#)
- [Manually constructing an IAM authentication token \(p. 1702\)](#)
- [Connecting to a DB cluster \(p. 1704\)](#)

### Generating an IAM authentication token

If you are writing programs using the AWS SDK for Java, you can get a signed authentication token using the `RdsIamAuthTokenGenerator` class. Using this class requires that you provide AWS credentials. To do this, you create an instance of the `DefaultAWSCredentialsProviderChain` class. `DefaultAWSCredentialsProviderChain` uses the first AWS access key and secret key that it finds in the [default credential provider chain](#). For more information about AWS access keys, see [Managing access keys for IAM users](#).

After you create an instance of `RdsIamAuthTokenGenerator`, you can call the `getAuthToken` method to obtain a signed token. Provide the AWS Region, host name, port number, and user name. The following code example illustrates how to do this.

```
package com.amazonaws.codesamples;

import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {

    public static void main(String[] args) {

        String region = "us-west-2";
        String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        System.out.println(generateAuthToken(region, hostname, port, username));
    }

    static String generateAuthToken(String region, String hostName, String port, String
username) {

        RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
            .credentials(new DefaultAWSCredentialsProviderChain())
            .region(region)
            .build();

        String authToken = generator.getAuthToken(
            GetIamAuthTokenRequest.builder()
                .hostname(hostName)
                .port(Integer.parseInt(port))
                .userName(username)
                .build());
    }

    return authToken;
}
```

```
}
```

## Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use `RdsIamAuthTokenGenerator`. This class creates an authentication token for you, and then signs it using AWS signature version 4. For more information, see [Signature version 4 signing process](#) in the *AWS General Reference*.

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```
package com.amazonaws.codesamples;

import com.amazonaws.SdkClientException;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.SigningAlgorithm;
import com.amazonaws.util.BinaryUtils;
import org.apache.commons.lang3.StringUtils;

import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import java.nio.charset.Charset;
import java.security.MessageDigest;
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.SortedMap;
import java.util.TreeMap;

import static com.amazonaws.auth.internal.SignerConstants.AWS4_TERMINATOR;
import static com.amazonaws.util.StringUtils.UTF8;

public class CreateRDSAuthTokenManually {
    public static String httpMethod = "GET";
    public static String action = "connect";
    public static String canonicalURIParameter = "/";
    public static SortedMap<String, String> canonicalQueryParameters = new TreeMap();
    public static String payload = StringUtils.EMPTY;
    public static String signedHeader = "host";
    public static String algorithm = "AWS4-HMAC-SHA256";
    public static String serviceName = "rds-db";
    public static String requestWithoutSignature;

    public static void main(String[] args) throws Exception {

        String region = "us-west-2";
        String instanceName = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        Date now = new Date();
        String date = new SimpleDateFormat("yyyyMMdd").format(now);
        String dateTimeStamp = new SimpleDateFormat("yyyyMMdd'T'HHmmss'Z'").format(now);
        DefaultAWSCredentialsProviderChain creds = new
DefaultAWSCredentialsProviderChain();
        String awsAccessKey = creds.getCredentials().getAWSAccessKeyId();
        String awsSecretKey = creds.getCredentials().getAWSSecretKey();
        String expiryMinutes = "900";

        System.out.println("Step 1: Create a canonical request:");
        String canonicalString = createCanonicalString(username, awsAccessKey, date,
dateTimeStamp, region, expiryMinutes, instanceName, port);
        System.out.println(canonicalString);
        System.out.println();
    }
}
```

```

        System.out.println("Step 2: Create a string to sign:");
        String stringToSign = createStringToSign(dateTimeStamp, canonicalString,
awsAccessKey, date, region);
        System.out.println(stringToSign);

    }
}
}

```

## Connecting to a DB cluster

The following code example shows how to generate an authentication token, and then use it to connect to a cluster running Aurora MySQL.

To run this code example, you need the [AWS SDK for Java](#), found on the AWS site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with `mysql-connector-java-5.1.33-bin.jar`.
- An intermediate certificate for Amazon Aurora that is specific to an AWS Region. (For more information, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.
- Modify the values of the following variables as needed:
  - `RDS_INSTANCE_HOSTNAME` – The host name of the DB cluster that you want to access.
  - `RDS_INSTANCE_PORT` – The port number used for connecting to your PostgreSQL DB cluster.
  - `REGION_NAME` – The AWS Region where the DB cluster is running.
  - `DB_USER` – The database account that you want to access.
  - `SSL_CERTIFICATE` – An SSL certificate for Amazon Aurora that is specific to an AWS Region.

To download a certificate for your AWS Region, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#). Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains AWS credentials from the [default credential provider chain](#).

```
package com.amazonaws.samples;

import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

## Connecting to your DB cluster using IAM authentication and the AWS SDK for Python (Boto3)

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Python (Boto3) as described following.

### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication \(p. 1685\)](#)
- [Creating and using an IAM policy for IAM database access \(p. 1686\)](#)
- [Creating a database account using IAM authentication \(p. 1689\)](#)

In addition, make sure the imported libraries in the sample code exist on your system.

### Examples

The code examples use profiles for shared credentials. For information about specifying credentials, see [Credentials](#) in the AWS SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the [AWS SDK for Python \(Boto3\)](#), found on the AWS site.

Modify the values of the following variables as needed:

- **ENDPOINT** – The endpoint of the DB cluster that you want to access
- **PORT** – The port number used for connecting to your DB cluster
- **USER** – The database account that you want to access
- **REGION** – The AWS Region where the DB cluster is running
- **DBNAME** – The database that you want to access
- **SSLCERTIFICATE** – The full path to the SSL certificate for Amazon Aurora

For `ssl_ca`, specify an SSL certificate. To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1642\)](#).

This code connects to an Aurora MySQL DB cluster.

Before running this code, install Connector/Python version 8.0 by following the instructions in [Connector/Python Installation](#) in the MySQL documentation.

```

import mysql.connector
import sys
import boto3
import os

ENDPOINT="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
Region=REGION)

try:
    conn = mysql.connector.connect(host=ENDPOINT, user=USER, passwd=token, port=PORT,
database=DBNAME, ssl_ca='SSLCERTIFICATE')
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))

```

This code connects to an Aurora PostgreSQL DB cluster.

Before running this code, install `psycopg2` by following the instructions in [Psycopg documentation](#).

```

import psycopg2
import sys
import boto3
import os

ENDPOINT="postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER,
password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))

```

## Troubleshooting Amazon Aurora identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Aurora and IAM.

### Topics

- [I'm not authorized to perform an action in Aurora \(p. 1710\)](#)
- [I'm not authorized to perform iam:PassRole \(p. 1710\)](#)
- [I want to view my access keys \(p. 1710\)](#)
- [I'm an administrator and want to allow others to access Aurora \(p. 1711\)](#)
- [I want to allow people outside of my AWS account to access my Aurora resources \(p. 1711\)](#)

### I'm not authorized to perform an action in Aurora

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a `widget` but does not have `rds:GetWidget` permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:  
rds:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the `my-example-widget` resource using the `rds:GetWidget` action.

### I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password. Ask that person to update your policies to allow you to pass a role to Aurora.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in Aurora. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the `iam:PassRole` action.

### I want to view my access keys

After you create your IAM user access keys, you can view your access key ID at any time. However, you can't view your secret access key again. If you lose your secret key, you must create a new access key pair.

Access keys consist of two parts: an access key ID (for example, `AKIAIOSFODNN7EXAMPLE`) and a secret access key (for example, `wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY`). Like a user name and

password, you must use both the access key ID and secret access key together to authenticate your requests. Manage your access keys as securely as you do your user name and password.

**Important**

Do not provide your access keys to a third party, even to help [find your canonical user ID](#). By doing this, you might give someone permanent access to your account.

When you create an access key pair, you are prompted to save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must add new access keys to your IAM user. You can have a maximum of two access keys. If you already have two, you must delete one key pair before creating a new one. To view instructions, see [Managing access keys](#) in the *IAM User Guide*.

## I'm an administrator and want to allow others to access Aurora

To enable others to access Aurora, you must create an IAM entity (user or role) for the person or application that needs access. They use the credentials for that entity to access AWS. You must then attach a policy to the entity that grants them the correct permissions in Aurora.

To get started right away, see [Creating your first IAM delegated user and group](#) in the *IAM User Guide*.

## I want to allow people outside of my AWS account to access my Aurora resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Aurora supports these features, see [How Amazon Aurora works with IAM \(p. 1657\)](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the *IAM User Guide*.
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

## Logging and monitoring in Amazon Aurora

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon Aurora resources and responding to potential incidents:

### Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

## AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon Aurora. CloudTrail captures all API calls for Amazon Aurora as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon Aurora, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Monitoring Amazon Aurora API calls in AWS CloudTrail \(p. 615\)](#).

## Enhanced Monitoring

Amazon Aurora provides metrics in real time for the operating system (OS) that your DB cluster runs on. You can view the metrics for your DB cluster using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see [Monitoring OS metrics with Enhanced Monitoring \(p. 518\)](#).

## Amazon RDS Performance Insights

Performance Insights expands on existing Amazon Aurora monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora \(p. 461\)](#).

## Database Logs

You can view, download, and watch database logs using the AWS Management Console, AWS CLI, or RDS API. For more information, see [Monitoring Amazon Aurora log files \(p. 597\)](#).

## Amazon Aurora Recommendations

Amazon Aurora provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB cluster configuration, usage, and performance data. For more information, see [Viewing Amazon Aurora recommendations \(p. 444\)](#).

## Amazon Aurora Event Notification

Amazon Aurora uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon Aurora event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see [Working with Amazon RDS event notification \(p. 572\)](#).

## AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon Aurora-related checks:

- Amazon Aurora Idle DB Instances
- Amazon Aurora Security Group Access Risk
- Amazon Aurora Backups
- Amazon Aurora Multi-AZ
- Aurora DB Instance Accessibility

For more information on these checks, see [Trusted Advisor best practices \(checks\)](#).

## Database activity streams

Database activity streams can protect your databases from internal threats by controlling DBA access to the database activity streams. Thus, the collection, transmission, storage, and subsequent

processing of the database activity stream is beyond the access of the DBAs that manage the database. Database activity streams can provide safeguards for your database and meet compliance and regulatory requirements. For more information, see [Monitoring Amazon Aurora with Database Activity Streams \(p. 619\)](#).

For more information about monitoring Aurora see [Monitoring metrics in an Amazon Aurora cluster \(p. 427\)](#).

# Compliance validation for Amazon Aurora

Third-party auditors assess the security and compliance of Amazon Aurora as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see [AWS services in scope by compliance program](#). For general information, see [AWS compliance programs](#).

You can download third-party audit reports using AWS Artifact. For more information, see [Downloading reports in AWS Artifact](#).

Your compliance responsibility when using Amazon Aurora is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- [Security and compliance quick start guides](#) – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- [Architecting for HIPAA security and compliance whitepaper](#) – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- [AWS compliance resources](#) – This collection of workbooks and guides that might apply to your industry and location.
- [AWS Config](#) – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- [AWS Security Hub](#) – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.

# Resilience in Amazon Aurora

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see [AWS global infrastructure](#).

In addition to the AWS global infrastructure, Aurora offers features to help support your data resiliency and backup needs.

## Backup and restore

Aurora backs up your cluster volume automatically and retains restore data for the length of the *backup retention period*. Aurora backups are continuous and incremental so you can quickly restore to any point within the backup retention period. No performance impact or interruption of database service occurs as backup data is being written. You can specify a backup retention period, from 1 to 35 days, when you create or modify a DB cluster.

If you want to retain a backup beyond the backup retention period, you can also take a snapshot of the data in your cluster volume. Aurora retains incremental restore data for the entire backup retention period. Thus, you need to create a snapshot only for data that you want to retain beyond the backup retention period. You can create a new DB cluster from the snapshot.

You can recover your data by creating a new Aurora DB cluster from the backup data that Aurora retains, or from a DB cluster snapshot that you have saved. You can quickly create a new copy of a DB cluster from backup data to any point in time during your backup retention period. The continuous and incremental nature of Aurora backups during the backup retention period means you don't need to take frequent snapshots of your data to improve restore times.

For more information, see [Backing up and restoring an Amazon Aurora DB cluster \(p. 368\)](#).

## Replication

Aurora Replicas are independent endpoints in an Aurora DB cluster, best used for scaling read operations and increasing availability. Up to 15 Aurora Replicas can be distributed across the Availability Zones that a DB cluster spans within an AWS Region. The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the data in the cluster volume is represented as a single, logical volume to the primary DB instance and to Aurora Replicas in the DB cluster. If the primary DB instance fails, an Aurora Replica is promoted to be the primary DB instance.

Aurora also supports replication options that are specific to Aurora MySQL and Aurora PostgreSQL.

For more information, see [Replication with Amazon Aurora \(p. 73\)](#).

## Failover

Aurora stores copies of the data in a DB cluster across multiple Availability Zones in a single AWS Region. This storage occurs regardless of whether the DB instances in the DB cluster span multiple Availability Zones. When you create Aurora Replicas across Availability Zones, Aurora automatically provisions and maintains them synchronously. The primary DB instance is synchronously replicated across Availability Zones to Aurora Replicas to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups. Running a DB cluster with high availability can enhance availability during

planned system maintenance, and help protect your databases against failure and Availability Zone disruption.

For more information, see [High availability for Amazon Aurora \(p. 71\)](#).

# Infrastructure security in Amazon Aurora

As a managed service, Amazon RDS is protected by the AWS global network security procedures that are described in the [Amazon Web Services: Overview of security processes](#) whitepaper.

You use AWS published API calls to access Amazon Aurora through the network. Clients must support Transport Layer Security (TLS) 1.0. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [AWS Security Token Service \(AWS STS\)](#) to generate temporary security credentials to sign requests.

In addition, Aurora offers features to help support infrastructure security.

## Security groups

Security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off to a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group.

For more information, see [Controlling access with security groups \(p. 1721\)](#).

## Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the *Public accessibility* parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the *Public accessibility* parameter.

For more information, see [Hiding a DB cluster in a VPC from the internet \(p. 1735\)](#).

### Note

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see [Internetwork traffic privacy \(p. 1652\)](#).

# Amazon RDS API and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by [AWS PrivateLink](#).

AWS PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances and DB clusters. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see [Elastic network interfaces](#) in the *Amazon EC2 User Guide*.

For more information about VPC endpoints, see [Interface VPC endpoints \(AWS PrivateLink\)](#) in the *Amazon VPC User Guide*. For more information about RDS API operations, see [Amazon RDS API Reference](#).

You don't need an interface VPC endpoint to connect to a DB cluster. For more information, see [Scenarios for accessing a DB cluster in a VPC \(p. 1739\)](#).

## Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review [Interface endpoint properties and limitations](#) in the *Amazon VPC User Guide*.

All RDS API operations relevant to managing Amazon Aurora resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see [Controlling access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

## Availability

Amazon RDS API currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)

- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- Europe (Milan)
- Middle East (Bahrain)
- South America (São Paulo)
- China (Beijing)
- China (Ningxia)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

## Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see [Creating an interface endpoint](#) in the *Amazon VPC User Guide*.

Create a VPC endpoint for Amazon RDS API using the service name `com.amazonaws.region.rds`.

Excluding AWS Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the AWS Region, for example `rds.us-east-1.amazonaws.com`. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint using `rds-api.cn-north-1.amazonaws.com.cn` and `rds-api.cn-northwest-1.amazonaws.com.cn`, respectively.

For more information, see [Accessing a service through an interface endpoint](#) in the *Amazon VPC User Guide*.

## Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see [Controlling access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

### Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```
{  
    "Statement": [  
        {
```

```
        "Principal": "*",
        "Effect": "Allow",
        "Action": [
            "rds:CreateDBInstance",
            "rds:ModifyDBInstance",
            "rds>CreateDBSnapshot"
        ],
        "Resource": "*"
    }
}
```

#### Example: VPC endpoint policy that denies all access from a specified AWS account

The following VPC endpoint policy denies AWS account 123456789012 all access to resources using the endpoint. The policy allows all actions from other accounts.

```
{
    "Statement": [
        {
            "Action": "*",
            "Effect": "Allow",
            "Resource": "*",
            "Principal": "*"
        },
        {
            "Action": "*",
            "Effect": "Deny",
            "Resource": "*",
            "Principal": {
                "AWS": [
                    "123456789012"
                ]
            }
        }
    ]
}
```

## Security best practices for Amazon Aurora

Use AWS Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon Aurora resources. Such resources include DB clusters, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB clusters.

- Create an individual IAM user for each person who manages Amazon Aurora resources, including yourself. Don't use AWS root credentials to manage Amazon Aurora resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure AWS Secrets Manager to automatically rotate the secrets for Amazon Aurora. For more information, see [Rotating your AWS Secrets Manager secrets](#) in the *AWS Secrets Manager User Guide*. You can also retrieve the credential from AWS Secrets Manager programmatically. For more information, see [Retrieving the secret value](#) in the *AWS Secrets Manager User Guide*.

For more information about Amazon Aurora security, see [Security in Amazon Aurora \(p. 1634\)](#). For more information about IAM, see [AWS Identity and Access Management](#). For information on IAM best practices, see [IAM best practices](#).

Use the AWS Management Console, the AWS CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

## Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off for a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group. You can specify up to 20 rules in a security group.

### Overview of VPC security groups

Each VPC security group rule makes it possible for a specific source to access a DB cluster in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB clusters. Outbound traffic rules apply only if the DB cluster acts as a client. You must use the [Amazon EC2 API](#) or the **Security Group** option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the clusters in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for Aurora MySQL DB instances in your VPC.

#### Note

In an Aurora DB cluster, the VPC security group associated with the DB cluster is also associated with all of the DB instances in the DB cluster. If you change the VPC security group for the DB cluster or for a DB instance, the change is applied automatically to all of the DB instances in the DB cluster.

For more information on VPC security groups, see [Security groups in the Amazon Virtual Private Cloud User Guide](#).

#### Note

If your DB cluster is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see [Internetwork traffic privacy \(p. 1652\)](#).

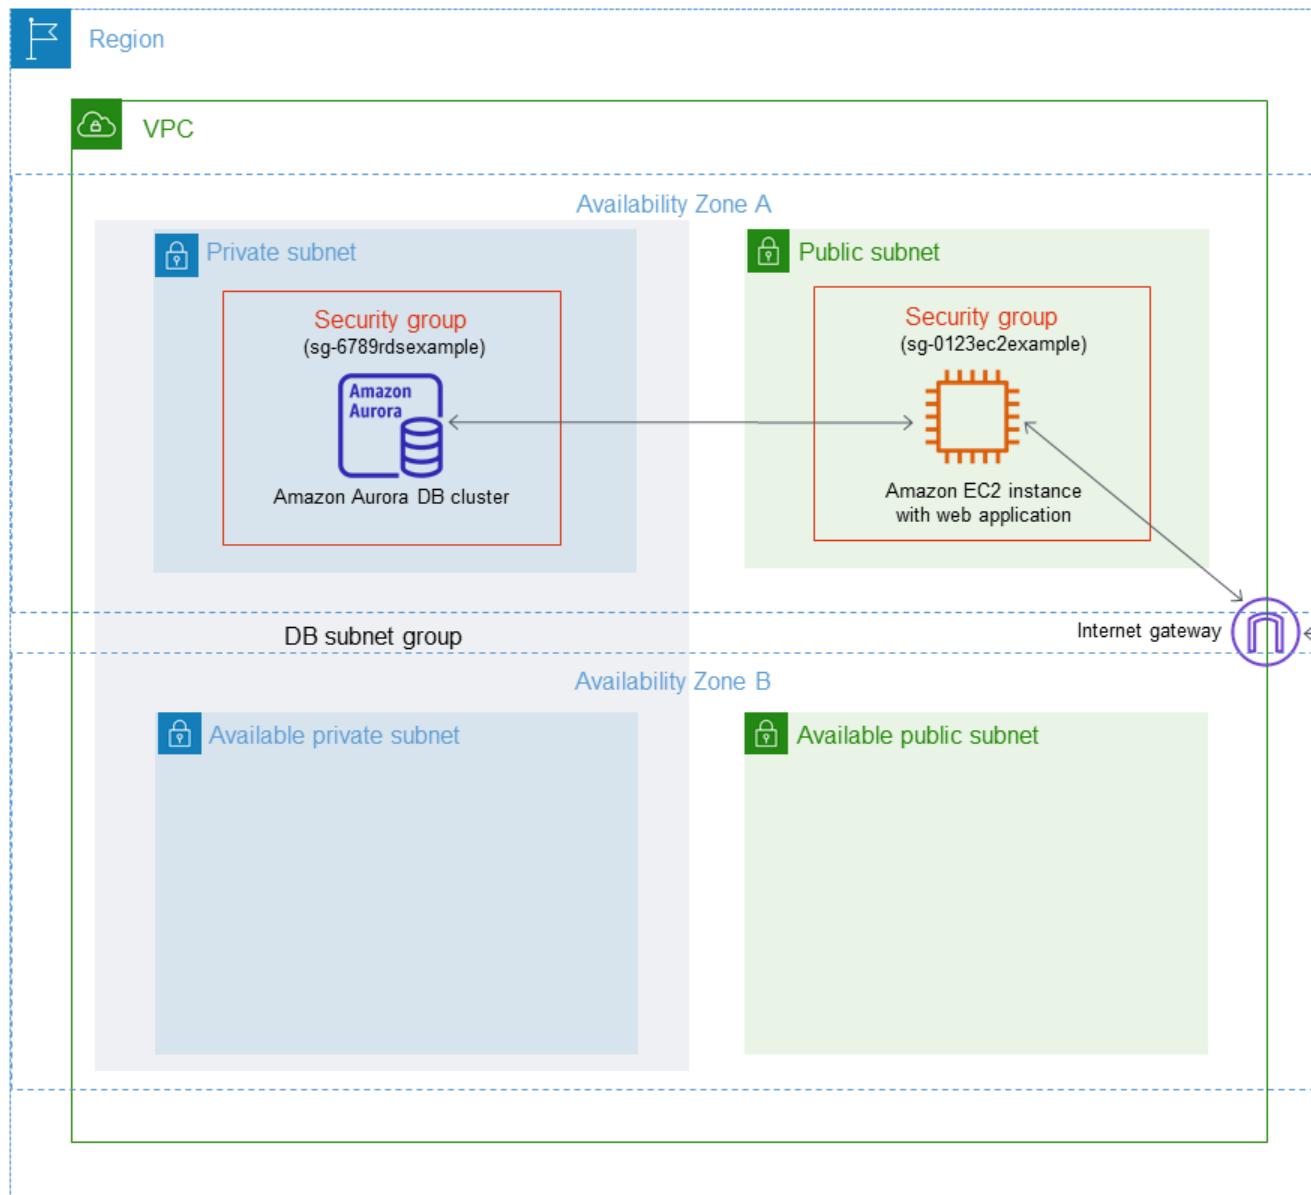

## Security group scenario

A common use of a DB cluster in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the AWS Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, sg-0123ec2example) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.

2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (`sg-0123ec2example`) that you created in the previous step.
3. Create a second VPC security group (for example, `sg-6789rdsexample`) and create a new rule by specifying the VPC security group that you created in step 1 (`sg-0123ec2example`) as the source.
4. Create a new DB cluster and add the DB cluster to the VPC security group (`sg-6789rdsexample`) that you created in the previous step. When you create the DB cluster, use the same port number as the one specified for the VPC security group (`sg-6789rdsexample`) rule that you created in step 3.

The following diagram shows this scenario.

For detailed instructions about configuring a VPC for this scenario, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\) \(p. 1744\)](#). For more information about using a VPC, see [Amazon VPC VPCs and Amazon Aurora \(p. 1729\)](#).

## Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see [Provide access to the DB cluster in the VPC by creating a security group \(p. 90\)](#) and [Security groups](#) in the *Amazon Virtual Private Cloud User Guide*.

## Associating a security group with a DB cluster

You can associate a security group with a DB cluster by using **Modify cluster** on the RDS console, the `ModifyDBCluster` Amazon RDS API, or the `modify-db-cluster` AWS CLI command.

For information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster \(p. 248\)](#).

## Master user account privileges

When you create a new DB cluster, the default master user that you use gets certain privileges for that DB cluster. You can't change the master user name after the DB cluster is created.

### Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

### Note

If you accidentally delete the permissions for the master user, you can restore them by modifying the DB cluster and setting a new master user password. For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster \(p. 248\)](#).

The following table shows the privileges and database roles the master user gets for each of the database engines.

Database engine	System privilege	Database role
Amazon Aurora MySQL	CREATE, DROP, GRANT OPTION, REFERENCES, EVENT, ALTER, DELETE, INDEX, INSERT, SELECT, UPDATE, CREATE TEMPORARY TABLES, LOCK TABLES, TRIGGER, CREATE VIEW, SHOW VIEW, LOAD FROM S3, SELECT INTO S3, ALTER ROUTINE, CREATE ROUTINE, EXECUTE, CREATE USER, PROCESS, SHOW DATABASES , RELOAD, REPLICATION CLIENT, REPLICATION SLAVE	—
Amazon Aurora PostgreSQL	LOGIN, NOSUPERUSER, INHERIT, CREATEDB, CREATEROLE, NOREPLICATION, VALID UNTIL 'infinity'	RDS_SUPERUSER For more information about RDS_SUPERUSER, see <a href="#">Understanding PostgreSQL roles and permissions (p. 1019)</a> .

# Using service-linked roles for Amazon Aurora

Amazon Aurora uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Amazon Aurora. Service-linked roles are predefined by Amazon Aurora and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes using Amazon Aurora easier because you don't have to manually add the necessary permissions. Amazon Aurora defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon Aurora can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon Aurora resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

## Service-linked role permissions for Amazon Aurora

Amazon Aurora uses the service-linked role named AWSServiceRoleForRDS to allow Amazon RDS to call AWS services on behalf of your DB clusters.

The AWSServiceRoleForRDS service-linked role trusts the following services to assume the role:

- rds.amazonaws.com

This service-linked role has a permissions policy attached to it called `AmazonRDSServiceRolePolicy` that grants it permissions to operate in your account. The role permissions policy allows Amazon Aurora to complete the following actions on the specified resources:

```
        "ec2:DescribeCoipPools",
        "ec2:DescribeInternetGateways",
        "ec2:DescribeLocalGatewayRouteTablePermissions",
        "ec2:DescribeLocalGatewayRouteTables",
        "ec2:DescribeLocalGatewayRouteTableVpcAssociations",
        "ec2:DescribeLocalGateways",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSubnets",
        "ec2:DescribeVpcAttribute",
        "ec2:DescribeVpcs",
        "ec2:DisassociateAddress",
        "ec2:ModifyNetworkInterfaceAttribute",
        "ec2:ModifyVpcEndpoint",
        "ec2:ReleaseAddress",
        "ec2:RevokeSecurityGroupIngress",
        "ec2>CreateVpcEndpoint",
        "ec2:DescribeVpcEndpoints",
        "ec2:DeleteVpcEndpoints",
        "ec2:AssignPrivateIpAddresses",
        "ec2:UnassignPrivateIpAddresses"
    ],
    "Resource": "*"
},
{
    "Effect": "Allow",
    "Action": [
        "sns:Publish"
    ],
    "Resource": "*"
},
{
    "Effect": "Allow",
    "Action": [
        "logs>CreateLogGroup"
    ],
    "Resource": [
        "arn:aws:logs:***:log-group:/aws/rds/*",
        "arn:aws:logs:***:log-group:/aws/docdb/*",
        "arn:aws:logs:***:log-group:/aws/neptune/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "logs>CreateLogStream",
        "logs:PutLogEvents",
        "logs:DescribeLogStreams"
    ],
    "Resource": [
        "arn:aws:logs:***:log-group:/aws/rds/*:log-stream:*",
        "arn:aws:logs:***:log-group:/aws/docdb/*:log-stream:*",
        "arn:aws:logs:***:log-group:/aws/neptune/*:log-stream:*
```

```
        "Resource": [
            "arn:aws:kinesis:*::stream/aws-rds-das-*"
        ],
    },

    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "cloudwatch:namespace": [
                "AWS/DocDB",
                "AWS/Neptune",
                "AWS/RDS",
                "AWS/Usage"
            ]
        }
    }
},
{
    "Effect": "Allow",
    "Action": [
        "secretsmanager:GetSecretValue",
        "secretsmanager:DescribeSecret",
        "secretsmanager:RestoreSecret",
        "secretsmanager>CreateSecret",
        "secretsmanager>DeleteSecret",
        "secretsmanager:UpdateSecret"
    ],
    "Resource": "arn:aws:secretsmanager:*::secret:rds-sqlserver-ssrs!*"
}
]
```

#### Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

**Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**

Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/rds.amazonaws.com/
AWSServiceRoleForRDS",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName": "rds.amazonaws.com"
        }
    }
}
```

For more information, see [Service-linked role permissions in the \*IAM User Guide\*](#).

## Creating a service-linked role for Amazon Aurora

You don't need to manually create a service-linked role. When you create a DB cluster, Amazon Aurora creates the service-linked role for you.

### Important

If you were using the Amazon Aurora service before December 1, 2017, when it began supporting service-linked roles, then Amazon Aurora created the AWSServiceRoleForRDS role in your account. To learn more, see [A new role appeared in my AWS account](#).

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB cluster, Amazon Aurora creates the service-linked role for you again.

## Editing a service-linked role for Amazon Aurora

Amazon Aurora does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

## Deleting a service-linked role for Amazon Aurora

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB clusters before you can delete the service-linked role.

### Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

#### To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the AWSServiceRoleForRDS role.
3. On the **Summary** page for the chosen role, choose the **Access Advisor** tab.
4. On the **Access Advisor** tab, review recent activity for the service-linked role.

#### Note

If you are unsure whether Amazon Aurora is using the AWSServiceRoleForRDS role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the AWS Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the AWSServiceRoleForRDS role, you must first delete *all* of your DB clusters.

### Deleting all of your clusters

Use one of the following procedures to delete a single cluster. Repeat the procedure for each of your clusters.

#### To delete a cluster (console)

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the **Databases** list, choose the cluster that you want to delete.
3. For **Cluster Actions**, choose **Delete**.

4. Choose **Delete**.

**To delete a cluster (CLI)**

See [delete-db-cluster](#) in the *AWS CLI Command Reference*.

**To delete a cluster (API)**

See [DeleteDBCluster](#) in the *Amazon RDS API Reference*.

You can use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForRDS service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

# Amazon VPC VPCs and Amazon Aurora

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch AWS resources, such as Aurora DB clusters, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB cluster in a VPC.

Accounts have a default VPC. All new DB clusters are created in the default VPC unless you specify otherwise.

## Topics

- [Working with a DB cluster in a VPC \(p. 1729\)](#)
- [Scenarios for accessing a DB cluster in a VPC \(p. 1739\)](#)
- [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\) \(p. 1744\)](#)
- [Tutorial: Create a VPC for use with a DB cluster \(dual-stack mode\) \(p. 1749\)](#)

Following, you can find a discussion about VPC functionality relevant to Amazon Aurora DB clusters. For more information about Amazon VPC, see [Amazon VPC Getting Started Guide](#) and [Amazon VPC User Guide](#).

## Working with a DB cluster in a VPC

Your DB cluster is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the AWS Cloud. Amazon VPC makes it possible for you to launch AWS resources, such as an Amazon Aurora DB cluster or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your AWS account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon Aurora DB clusters in a VPC , see [Scenarios for accessing a DB cluster in a VPC \(p. 1739\)](#).

## Topics

- [Working with a DB cluster in a VPC \(p. 1729\)](#)
- [Working with DB subnet groups \(p. 1730\)](#)
- [Amazon Aurora IP addressing \(p. 1731\)](#)
- [Hiding a DB cluster in a VPC from the internet \(p. 1735\)](#)
- [Creating a DB cluster in a VPC \(p. 1736\)](#)

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon Aurora scenario:

- [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\) \(p. 1744\)](#)
- [Tutorial: Create a VPC for use with a DB cluster \(dual-stack mode\) \(p. 1749\)](#)

## Working with a DB cluster in a VPC

Here are some tips on working with a DB cluster in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the AWS Region where you want to deploy your DB cluster. A *subnet* is a segment of a VPC's IP address range that you can specify and that you can use to group DB clusters based on your security and operational needs.
- If you want your DB cluster in the VPC to be publicly accessible, make sure to turn on the VPC attributes *DNS hostnames* and *DNS resolution*.
- Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The primary DB instance uses the Availability Zone that contains the subnet.
- Your VPC must have a VPC security group that allows access to the DB cluster.

For more information, see [Scenarios for accessing a DB cluster in a VPC \(p. 1739\)](#).

- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon Aurora to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.
- A VPC can have an *instance tenancy* attribute of either *default* or *dedicated*. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

If you choose to have your DB cluster in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB cluster must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see [Dedicated instances in the Amazon Elastic Compute Cloud User Guide](#).

For more information about the instance types that can be in a dedicated instance, see [Amazon EC2 dedicated instances](#) on the EC2 pricing page.

**Note**

When you set the instance tenancy attribute to dedicated for a DB cluster, it doesn't guarantee that the DB cluster will run on a dedicated host.

## Working with DB subnet groups

*Subnets* are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A *DB subnet group* is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters using the AWS CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given AWS Region. When creating a DB cluster in a VPC, you choose a DB subnet group for it. From the DB subnet group, Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The DB uses the Availability Zone that contains the subnet.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB cluster to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB cluster changes from public to private, it can affect DB cluster availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it. For more information, see [Amazon Aurora IP addressing \(p. 1731\)](#) and [Migrating to IPv6](#) in the *Amazon VPC User Guide*.

When Amazon Aurora creates a DB cluster in a VPC, it assigns a network interface to your DB cluster by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB cluster. We recommend this because the underlying IP address changes during failover.

**Note**

For each DB cluster that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon Aurora for recovery actions.

## Amazon Aurora IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon Aurora support both the Internet Protocol version 4 (IPv4) and IPv6 addressing protocols. By default, Amazon Aurora and Amazon VPC use the IPv4 addressing protocol. You can't turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB clusters in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your Amazon VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

### Topics

- [IPv4 addresses \(p. 1731\)](#)
- [IPv6 addresses \(p. 1731\)](#)
- [Dual-stack mode \(p. 1732\)](#)

### IPv4 addresses

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as 10.0.0.0/16. A *DB subnet group* defines the range of IP addresses in this CIDR block that a DB cluster can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that's not reachable over the internet. You can use private IPv4 addresses for communication between your DB cluster and other resources, such as Amazon EC2 instances, in the same VPC. Each DB cluster has a private IP address for communication in the VPC.

A public IP address is an IPv4 address that's reachable from the internet. You can use public addresses for communication between your DB cluster and resources on the internet, such as a SQL client. You control whether your DB cluster receives a public IP address.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon Aurora scenario, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\) \(p. 1744\)](#).

### IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 addresses is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses. You can't choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

- The client is configured so that client to database traffic over IPv6 is allowed.
- RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.
- The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).

For more information about IPv6, see [IP Addressing in the Amazon VPC User Guide](#).

## Dual-stack mode

When a DB cluster can communicate over both the IPv4 and IPv6 addressing protocols, it's running in dual-stack mode. So, resources can communicate with the DB cluster over IPv4, IPv6, or both. RDS disables Internet Gateway access for IPv6 endpoints of private dual-stack mode DB instances. RDS does this to ensure that your IPv6 endpoints are private and can only be accessed from within your VPC.

### Topics

- [Dual-stack mode and DB subnet groups \(p. 1732\)](#)
- [Working with dual-stack mode DB instances \(p. 1732\)](#)
- [Modifying IPv4-only DB clusters to use dual-stack mode \(p. 1733\)](#)
- [Availability of dual-stack network DB clusters \(p. 1734\)](#)
- [Limitations for dual-stack network DB clusters \(p. 1735\)](#)

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon Aurora scenario, see [Tutorial: Create a VPC for use with a DB cluster \(dual-stack mode\) \(p. 1749\)](#).

### Dual-stack mode and DB subnet groups

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB cluster has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB cluster is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB cluster primary instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB cluster detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.

If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create new dual-stack mode DB cluster.

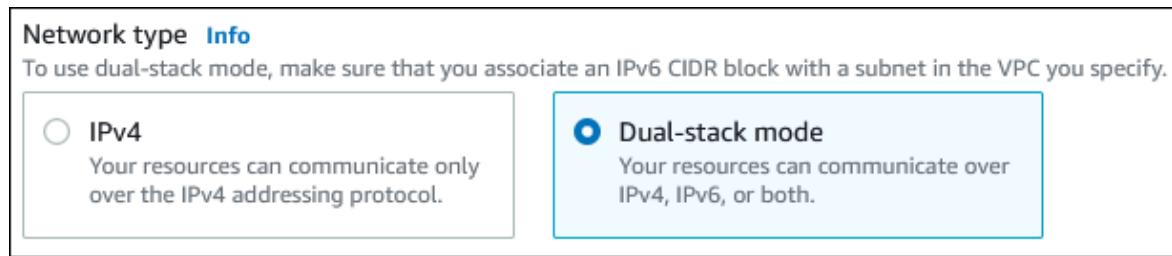

To determine whether a DB subnet group supports dual-stack mode by using the AWS Management Console, view the **Network type** on the details page of the DB subnet group. To determine whether a DB subnet group supports dual-stack mode by using the AWS CLI, call the [describe-db-subnet-groups](#) command and view `SupportedNetworkTypes` in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

### Working with dual-stack mode DB instances

When you create or modify a DB cluster, you can specify *dual-stack mode* to allow your resources to communicate with your DB cluster over IPv4, IPv6, or both.

When you use the AWS Management Console to create or modify a DB instance, you can specify dual-stack mode in the **Network type** section. The following image shows the **Network type** section in the console.

When you use the AWS CLI to create or modify a DB cluster, set the `--network-type` option to `DUAL` to use dual-stack mode. When you use the RDS API to create or modify a DB cluster, set the `NetworkType` parameter to `DUAL` to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the `NetworkTypeNotSupported` error is returned.

For more information about creating a DB cluster, see [Creating an Amazon Aurora DB cluster \(p. 127\)](#). For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster \(p. 248\)](#).

To determine whether a DB cluster is in dual-stack mode by using the console, view the **Network type** on the **Connectivity & security** tab for the DB cluster.

### Modifying IPv4-only DB clusters to use dual-stack mode

You can modify an IPv4-only DB cluster to use dual-stack mode. To do so, change the network type of the DB cluster. The modification might result in downtime.

Before modifying a DB cluster to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB cluster doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB cluster. If you modify the DB subnet group of a DB cluster before you change the DB cluster to use dual-stack mode, make sure that the DB subnet group is valid for the DB cluster before and after the change.

If you can't connect to the DB cluster after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow cross traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

The following limitations apply to modifying a DB cluster to use dual-stack mode:

- Dual-stack mode DB clusters can't be publicly accessible.
- DB clusters can't have an IPv6-only endpoint.

### To modify an IPv4-only DB cluster to use dual-stack mode

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:

- a. Associate an IPv6 CIDR block with your VPC.

For instructions, see [Associate an IPv6 CIDR block with your VPC](#) in the *Amazon VPC User Guide*.

- b. Attach the IPv6 CIDR block to all of the subnets in your DB subnet group.

For instructions, see [Associate an IPv6 CIDR block with your subnet](#) in the *Amazon VPC User Guide*.

- c. Confirm that the DB subnet group supports dual-stack mode.

If you are using the AWS Management Console, select the DB subnet group, and make sure that the **Supported network types** value is **Dual, IPv4**.

If you are using the AWS CLI, call the [describe-db-subnet-groups](#) command, and make sure that the `SupportedNetworkType` value for the DB instance is `Dual, IPv4`.

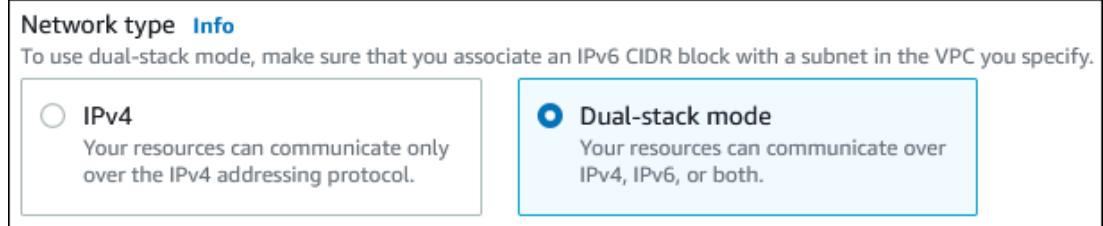

2. Modify the security group associated with the DB cluster to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.

For instructions, see [Security group rules](#) in the *Amazon VPC User Guide*.

3. Modify the DB cluster to support dual-stack mode. To do so, set the **Network type** to **Dual-stack mode**.

If you are using the console, make sure that the following settings are correct:

- **Network type – Dual-stack mode**

- **DB subnet group** – The DB subnet group that you configured in a previous step
- **Security group** – The security group that you configured in a previous step

If you are using the AWS CLI, make sure that the following settings are correct:

- `--network-type dual`
- `--db-subnet-group-name` – The DB subnet group that you configured in a previous step
- `--vpc-security-group-ids` – The VPC security group that you configured in a previous step

4. Confirm that the DB cluster supports dual-stack mode.

If you are using the console, choose the **Configuration** tab for the DB cluster. On that tab, make sure that the **Network type** value is **Dual-stack mode**.

If you are using the AWS CLI, call the [describe-db-clusters](#) command, and make sure that the `NetworkType` value for the DB cluster is `dual`.

Run the `dig` command on the writer DB instance endpoint to identify the IPv6 address associated with it.

```
dig db-instance-endpoint AAAA
```

Use the writer DB instance endpoint, not the IPv6 address, to connect to the DB cluster.

## Availability of dual-stack network DB clusters

The following DB engine versions support dual-stack network DB clusters:

- Aurora MySQL version 3.02.0 and higher

For more information about Aurora MySQL versions, see the [Release Notes for Aurora MySQL](#).

- Aurora PostgreSQL versions:

- 14.3 and higher 14 versions
- 13.7 and higher 13 versions

For more information about Aurora PostgreSQL versions, see the [Release Notes for Aurora PostgreSQL](#).

### Limitations for dual-stack network DB clusters

The following limitations apply to dual-stack network DB clusters:

- DB clusters can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).
- Amazon RDS doesn't support native IPv6 subnets.
- DB clusters that use dual-stack mode must be private. They can't be publicly accessible.
- Dual-stack mode doesn't support the db.r3 DB instance classes.
- You can't use RDS Proxy with dual-stack mode DB clusters.

## Hiding a DB cluster in a VPC from the internet

One common Amazon Aurora scenario is to have a VPC in which you have an EC2 instance with a public-facing web application and a DB cluster with a database that isn't publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. Amazon EC2 instances that function as web servers can be deployed in the public subnet. The DB clusters are deployed in the private subnet. In such a deployment, only the web servers have access to the DB clusters. For an illustration of this scenario, see [A DB cluster in a VPC accessed by an EC2 instance in the same VPC \(p. 1739\)](#).

When you launch a DB cluster inside a VPC, the DB cluster has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the **Public access** option to designate whether the DB cluster also has a public IP address in addition to the private IP address. If the DB cluster is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC. Access to the DB cluster is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB cluster doesn't include inbound rules that permit it. In addition, for a DB cluster to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see [Can't connect to Amazon RDS DB instance \(p. 1761\)](#)

You can modify a DB cluster to turn on or off public accessibility by modifying the **Public access** option. The following illustration shows the **Public access** option in the **Additional connectivity configuration** section. To set the option, open the **Additional connectivity configuration** section in the **Connectivity** section.

## Connectivity

For information about modifying a DB instance to set the **Public access** option, see [Modify a DB instance in a DB cluster \(p. 249\)](#).

## Creating a DB cluster in a VPC

The following procedures help you create a DB cluster in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

### Note

If you want your DB cluster in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes *DNS hostnames* and *DNS resolution*. For information about updating the DNS information for a VPC instance, see [Updating DNS support for your VPC](#).

Follow these steps to create a DB instance in a VPC:

- [Step 1: Create a VPC \(p. 1737\)](#)
- [Step 2: Create a DB subnet group \(p. 1737\)](#)
- [Step 3: Create a VPC security group \(p. 1739\)](#)
- [Step 4: Create a DB instance in the VPC \(p. 1739\)](#)

## Step 1: Create a VPC

Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the AWS Region.

For more information, see [Create a VPC with private and public subnets \(p. 1745\)](#), or see [Create a VPC](#) in the *Amazon VPC User Guide*.

## Step 2: Create a DB subnet group

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB clusters. A DB subnet group allows you to specify a particular VPC when you create DB clusters using the AWS CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the AWS Region. As a best practice, each DB subnet group should have at least one subnet for every Availability Zone in the AWS Region.

For a DB cluster to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see [Connect to the internet using an internet gateway](#) in the *Amazon VPC User Guide*.

When you create a DB cluster in a VPC, you can choose a DB subnet group. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with your DB cluster. If no DB subnet groups exist, Amazon Aurora creates a default subnet group when you create a DB cluster. Amazon Aurora creates and associates an Elastic Network Interface to your DB cluster with that IP address. The DB cluster uses the Availability Zone that contains the subnet.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

### To create a DB subnet group

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Subnet groups**.
3. Choose **Create DB Subnet Group**.
4. For **Name**, type the name of your DB subnet group.
5. For **Description**, type a description for your DB subnet group.
6. For **VPC**, choose the default VPC or the VPC that you created.
7. In the **Add subnets** section, choose the Availability Zones that include the subnets from **Availability Zones**, and then choose the subnets from **Subnets**.

## Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

### Subnet group details

#### Name

You won't be able to modify the name after your subnet group has been created.

mydbsubnetgroup

Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

#### Description

My DB Subnet Group

#### VPC

Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won't be able to choose a different VPC identifier after your subnet group has been created.

tutorial-vpc (vpc-068fe388385afc014)

### Add subnets

#### Availability Zones

Choose the Availability Zones that include the subnets you want to add.

Choose an availability zone

us-east-1a X us-east-1c X

#### Subnets

Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.

Select subnets

subnet-079bd4b8953aee1dd (10.0.0.0/24) X

subnet-057e85b72c46fdd9a (10.0.1.0/24) X

### Subnets selected (2)

Availability zone	Subnet ID	CIDR block
us-east-1a	subnet-079bd4b8953aee1dd	10.0.0.0/24
us-east-1c	subnet-057e85b72c46fdd9a	10.0.1.0/24

Cancel

Create

8. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

### Step 3: Create a VPC security group

Before you create your DB cluster, you can create a VPC security group to associate with your DB cluster. If you don't create a VPC security group, you can use the default security group when you create a DB cluster. For instructions on how to create a security group for your DB cluster, see [Create a VPC security group for a private DB cluster \(p. 1746\)](#), or see [Control traffic to resources using security groups](#) in the [Amazon VPC User Guide](#).

### Step 4: Create a DB instance in the VPC

In this step, you create a DB cluster and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

**Note**

If you want your DB cluster in the VPC to be publicly accessible, you must enable the VPC attributes *DNS hostnames* and *DNS resolution*. For more information, see [DNS attributes for your VPC](#) in the [Amazon VPC User Guide](#).

For details on how to create a DB cluster, see [Creating an Amazon Aurora DB cluster \(p. 127\)](#).

When prompted in the **Connectivity** section, enter the VPC name, the DB subnet group, and the VPC security group.

**Note**

Updating VPCs isn't currently supported for Aurora DB clusters.

## Scenarios for accessing a DB cluster in a VPC

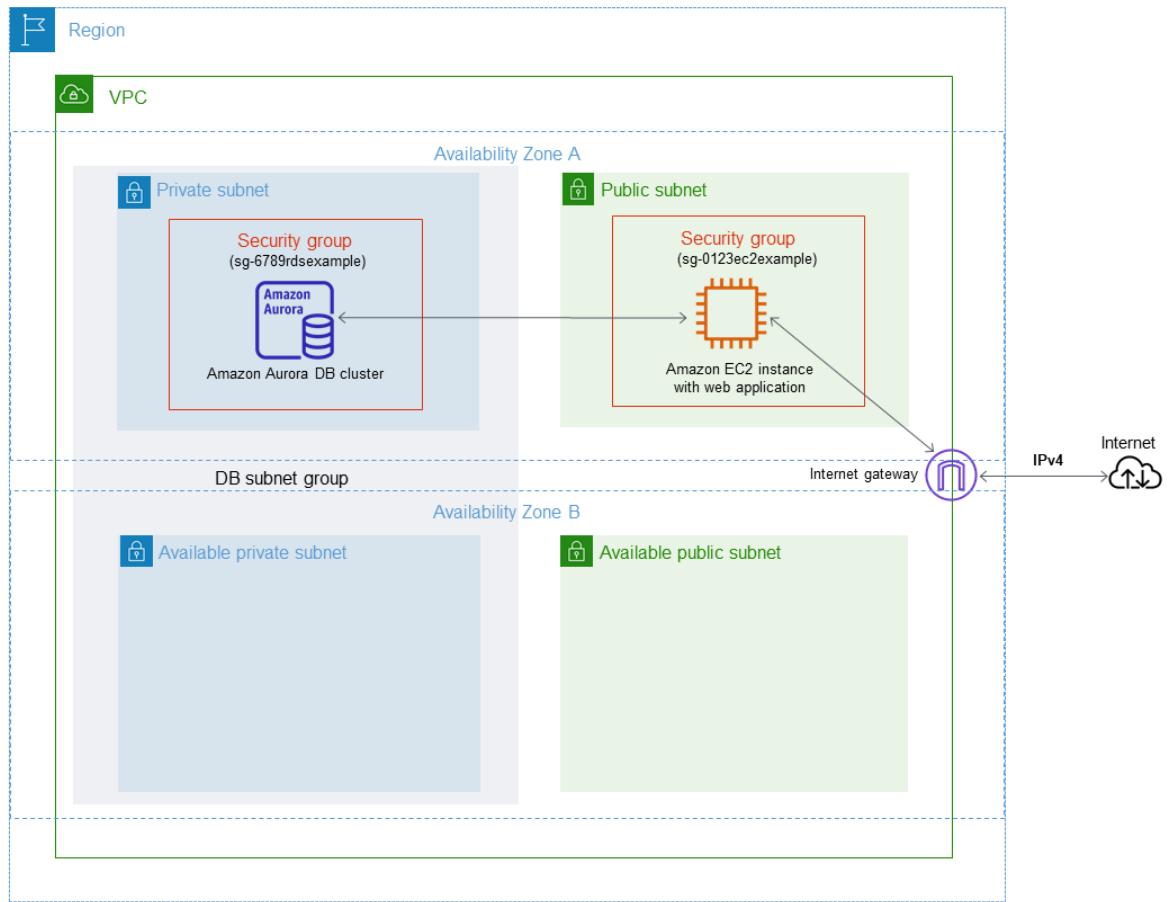

Amazon Aurora supports the following scenarios for accessing a DB cluster in a VPC:

- [An EC2 instance in the same VPC \(p. 1739\)](#)
- [An EC2 instance in a different VPC \(p. 1741\)](#)
- [A client application through the internet \(p. 1742\)](#)
- [A private network \(p. 1743\)](#)

### A DB cluster in a VPC accessed by an EC2 instance in the same VPC

A common use of a DB cluster in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC.

The following diagram shows this scenario.

The simplest way to manage access between EC2 instances and DB clusters in the same VPC is to do the following:

- Create a VPC security group for your DB clusters to be in. This security group can be used to restrict access to the DB clusters. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB cluster when you created it and an IP address you use to access the DB cluster for development or other purposes.
- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.
- Create custom rules in the security group for your DB clusters that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB clusters.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\) \(p. 1744\)](#).

**Tip**

You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. For more information, see [Configure automatic network connectivity with an EC2 instance \(p. 127\)](#).

**To create a rule in a VPC security group that allows connections from another security group, do the following:**

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc>.
2. In the navigation pane, choose **Security groups**.
3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB clusters. Choose the **Inbound rules** tab, and then choose **Edit inbound rules**.
4. On the **Edit inbound rules** page, choose **Add rule**.
5. For **Type**, choose the entry that corresponds to the port you used when you created your DB cluster, such as **MySQL/Aurora**.
6. In the **Source** box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with **All TCP** as the **Type** and your security group in the **Source** box. If you intend to use the UDP protocol, create a rule with **All UDP** as the **Type** and your security group in **Source**.
8. Choose **Save rules**.

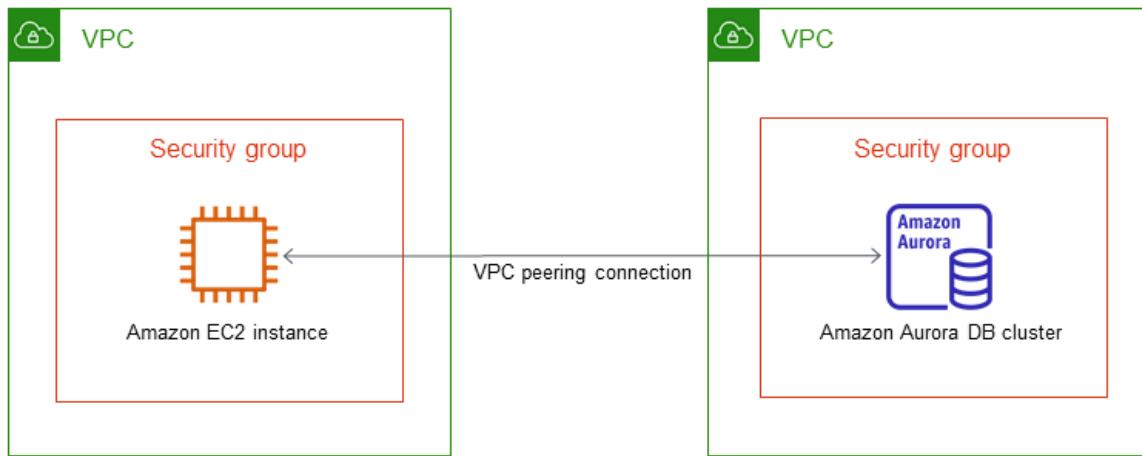

The following screen shows an inbound rule with a security group for its source.

Inbound rules			
Type	Protocol	Port range	Source
MySQL/Aurora	TCP	3306	sg-00bd2328e37926844 (tutorial-securitygroup)

## A DB cluster in a VPC accessed by an EC2 instance in a different VPC

When your DB clusters is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB cluster.

The following diagram shows this scenario.

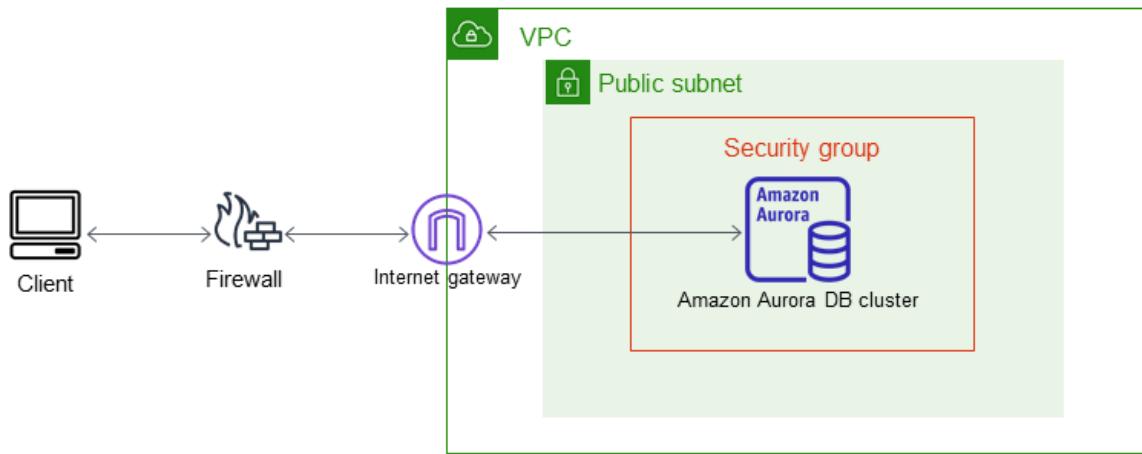

A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region. To learn more about VPC peering, see [VPC peering](#) in the *Amazon Virtual Private Cloud User Guide*.

## A DB cluster in a VPC accessed by a client application through the internet

To access a DB clusters in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.

We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon Aurora DB cluster that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB cluster.
- An internet gateway which connects the VPC to the internet and to other AWS products.

- A security group associated with the DB cluster. The security group's inbound rules allow your client application to access to your DB cluster.

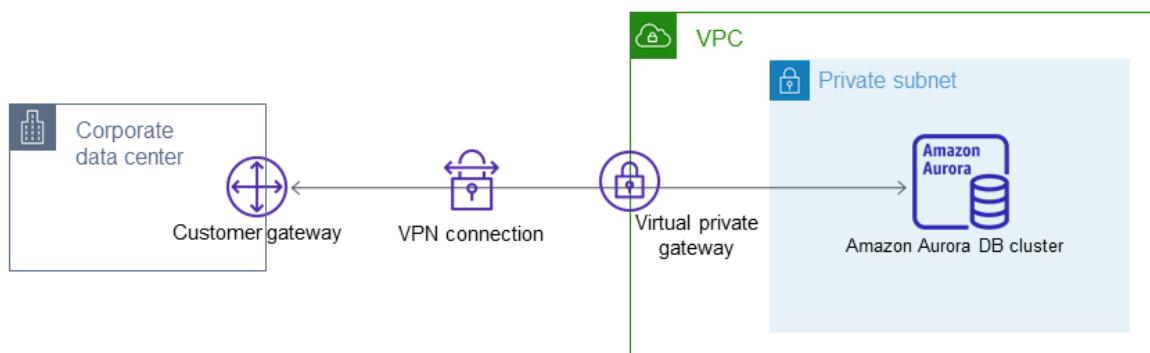

For information about creating a DB clusters in a VPC, see [Creating a DB cluster in a VPC \(p. 1736\)](#).

## A DB cluster in a VPC accessed by a private network

If your DB cluster isn't publicly accessible, you have the following options for accessing it from a private network:

- An AWS Site-to-Site VPN connection. For more information, see [What is AWS Site-to-Site VPN?](#)
- An AWS Direct Connect connection. For more information, see [What is AWS Direct Connect?](#)

The following diagram shows a scenario with an AWS Site-to-Site VPN connection.

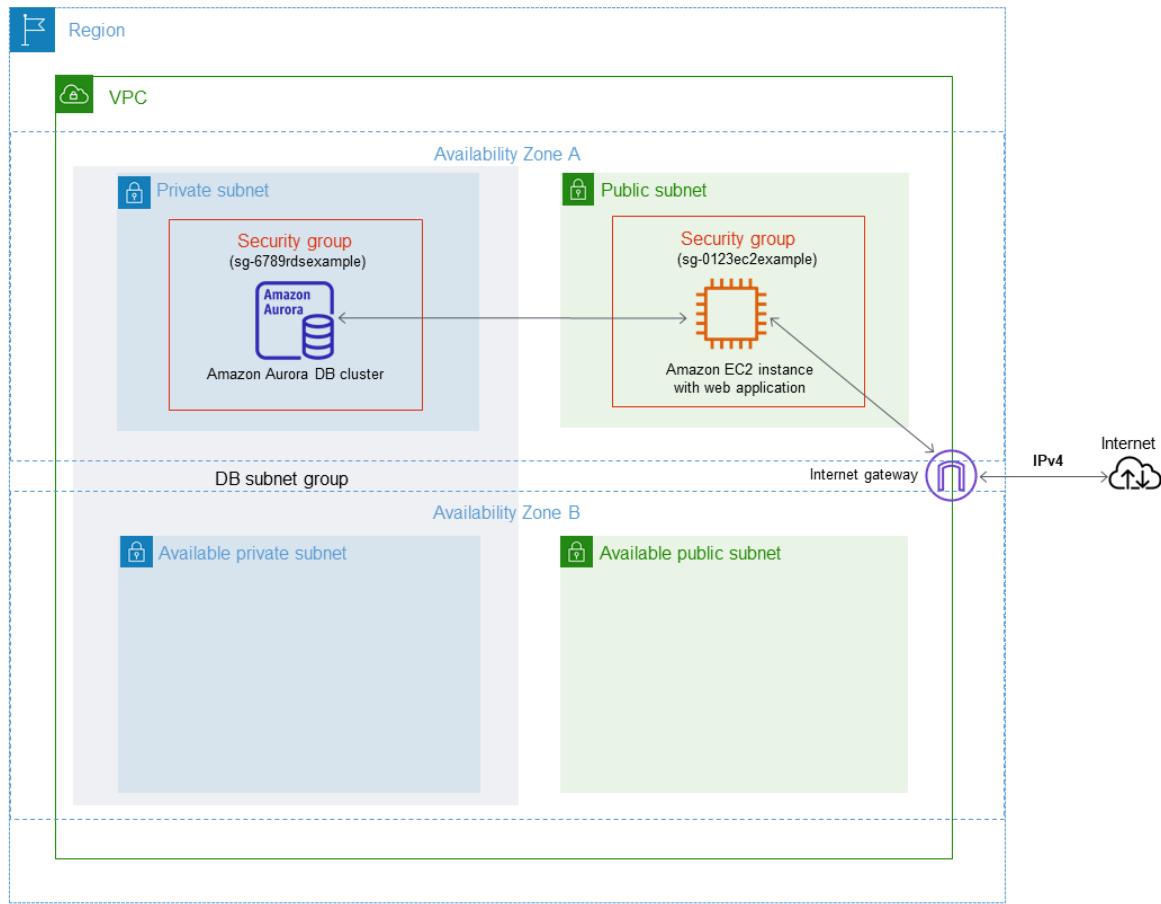

For more information, see [Internetwork traffic privacy \(p. 1652\)](#).

# Tutorial: Create a VPC for use with a DB cluster (IPv4 only)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see [Scenarios for accessing a DB cluster in a VPC \(p. 1739\)](#).

Because your DB cluster needs to be available only to your web server, and not to the public internet, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The web server can connect to the DB cluster because it is hosted within the same VPC. But the DB cluster isn't available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to configure more than one Aurora DB instance.

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For a tutorial that shows you how to create a web server for this VPC scenario, see [Tutorial: Create a web server and an Amazon Aurora DB cluster \(p. 107\)](#). For more information about Amazon VPC, see [Amazon VPC Getting Started Guide](#) and [Amazon VPC User Guide](#).

**Tip**

You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. The network configuration is similar to the one described in this tutorial. For more information, see [Configure automatic network connectivity with an EC2 instance \(p. 127\)](#).

## Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

### To create a VPC and subnets

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the top-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the **VPC settings**, set these values:
  - **Name tag auto-generation** – `tutorial`
  - **IPv4 CIDR block** – `10.0.0.0/16`
  - **IPv6 CIDR block** – `No IPv6 CIDR block`
  - **Tenancy** – `Default`
  - **Number of Availability Zones (AZs)** – `2`
  - **Customize AZs** – Keep the default values.
  - **Number of public subnet** – `2`
  - **Number of private subnets** – `2`
  - **Customize subnets CIDR blocks** – Keep the default values.
  - **NAT gateways (\$)** – `None`
  - **VPC endpoints** – `None`
  - **DNS options** – Keep the default values.
6. Choose **Create VPC**.

## Create a VPC security group for a public web server

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group that allow traffic to connect from the internet.

### To create a VPC security group

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
  - **Security group name:** `tutorial-securitygroup`
  - **Description:** `Tutorial Security Group`
  - **VPC:** Choose the VPC that you created earlier, for example: `vpc-identifier (tutorial-vpc)`
4. Add inbound rules to the security group.
  - a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab,

you can use the service at <https://checkip.amazonaws.com>. An example of an IP address is 203.0.113.25/32.

If you are connecting through an internet service provider (ISP) or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

**Warning**

If you use 0.0.0.0/0 for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

- b. In the **Inbound rules** section, choose **Add rule**.
  - c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities, and to upload content for your web server.
    - **Type:** **SSH**
    - **Source:** The IP address or range from Step a, for example: **203.0.113.25/32**.
  - d. Choose **Add rule**.
  - e. Set the following values for your new inbound rule to allow HTTP access to your web server:
    - **Type:** **HTTP**
    - **Source:** **0.0.0.0/0**
5. Choose **Create security group** to create the security group.

Note the security group ID because you need it later in this tutorial.

## Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clusters in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

### To create a VPC security group

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
  - **Security group name:** **tutorial-db-securitygroup**
  - **Description:** **Tutorial DB Instance Security Group**
  - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-vpc)**
4. Add inbound rules to the security group.
  - a. In the **Inbound rules** section, choose **Add rule**.
  - b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB cluster to store and retrieve data from your web application to your database.
    - **Type:** **MySQL/Aurora**
    - **Source:** The identifier of the **tutorial-securitygroup** security group that you created previously in this tutorial, for example: **sg-9edd5cfb**.
5. Choose **Create security group** to create the security group.

## Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. A DB subnet group makes it possible for you to specify a particular VPC when creating DB clusters.

### To create a DB subnet group

1. Identify the private subnets for your database in the VPC.
    - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
    - b. Choose **VPC Dashboard**, and then choose **Subnets**.
    - c. Note the subnet IDs of the subnets named **tutorial-subnet-private1-us-west-2a** and **tutorial-subnet-private2-us-west-2b**.

You need the subnet IDs when you create your DB subnet group.
  2. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.
  3. In the navigation pane, choose **Subnet groups**.
  4. Choose **Create DB subnet group**.
  5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
    - **Name:** `tutorial-db-subnet-group`
    - **Description:** `Tutorial DB Subnet Group`
    - **VPC:** `tutorial-vpc (vpc-identifier)`
  6. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.

For this tutorial, choose **us-west-2a** and **us-west-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.
  7. Choose **Create**.
- Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane at the bottom of the window. These details include all of the subnets associated with the group.

#### Note

If you created this VPC to complete [Tutorial: Create a web server and an Amazon Aurora DB cluster \(p. 107\)](#), create the DB cluster by following the instructions in [Create an Amazon Aurora DB cluster \(p. 108\)](#).

## Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

#### Note

If you added resources in the VPC that you created for this tutorial, you might need to delete these resources before you can delete the VPC. For example, these resources might include Amazon EC2 instances or Amazon RDS DB clusters. For more information, see [Delete your VPC](#) in the *Amazon VPC User Guide*.

### To delete a VPC and related resources

1. Delete the DB subnet group.

- a. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
  - b. In the navigation pane, choose **Subnet groups**.
  - c. Select the DB subnet group you want to delete, such as **tutorial-db-subnet-group**.
  - d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID.
    - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
    - b. Choose **VPC Dashboard**, and then choose **VPCs**.
    - c. In the list, identify the VPC that you created, such as **tutorial-vpc**.
    - d. Note the **VPC ID** of the VPC that you created. You need the VPC ID in later steps.
  3. Delete the security groups.
    - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
    - b. Choose **VPC Dashboard**, and then choose **Security Groups**.
    - c. Select the security group for the Amazon RDS DB instance, such as **tutorial-db-securitygroup**.
    - d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
    - e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-securitygroup**.
    - f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
  4. Delete the NAT gateway.
    - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
    - b. Choose **VPC Dashboard**, and then choose **NAT Gateways**.
    - c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.
    - d. For **Actions**, choose **Delete NAT gateway**.
    - e. On the confirmation page, enter **delete**, and then choose **Delete**.
  5. Delete the VPC.
    - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
    - b. Choose **VPC Dashboard**, and then choose **VPCs**.
    - c. Select the VPC you want to delete, such as **tutorial-vpc**.
    - d. For **Actions**, choose **Delete VPC**.

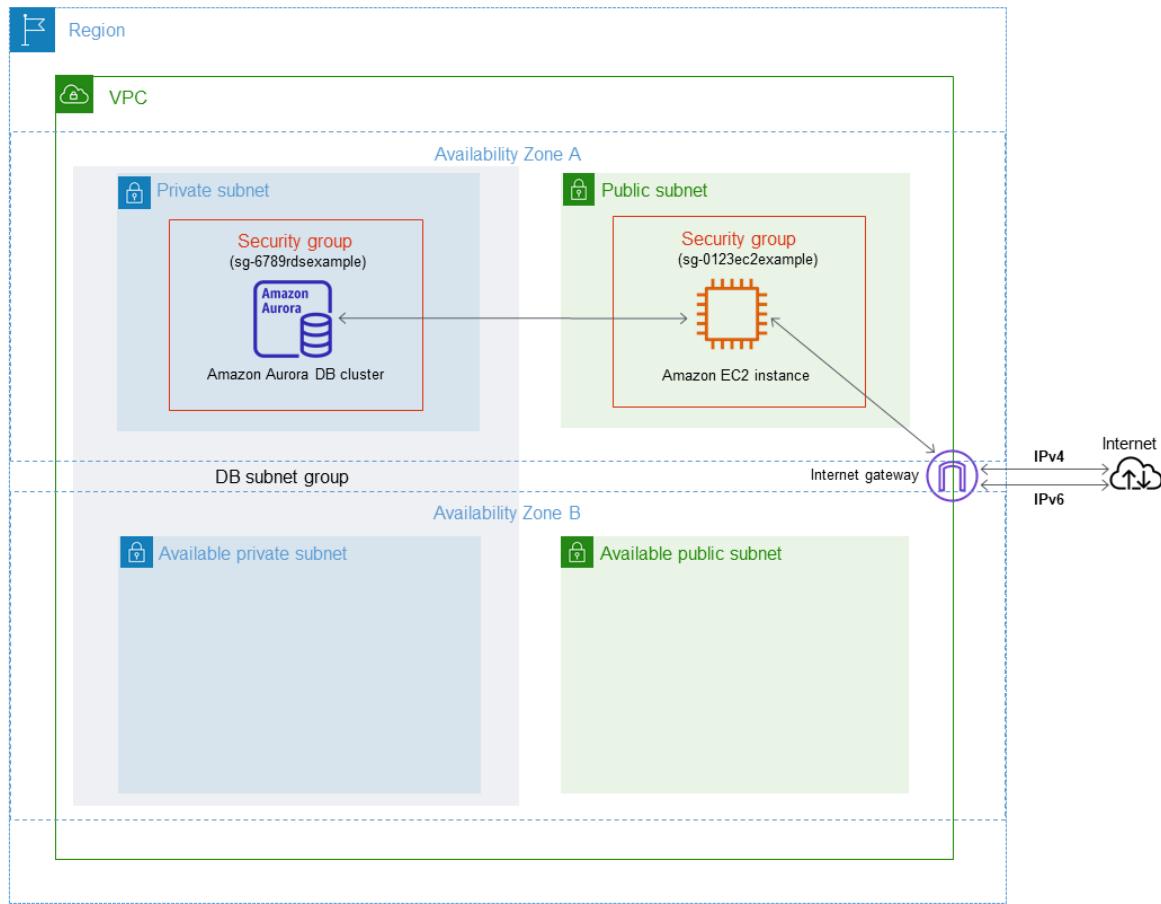

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

    - e. On the confirmation page, enter **delete**, and then choose **Delete**.
  6. Release the Elastic IP addresses:
    - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
    - b. Choose **Amazon EC2 Dashboard**, and then choose **Elastic IPs**.
    - c. Select the Elastic IP address you want to release.
    - d. For **Actions**, choose **Release Elastic IP addresses**.
    - e. On the confirmation page, choose **Release**.

## Tutorial: Create a VPC for use with a DB cluster (dual-stack mode)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC. In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode.

The following diagram shows this scenario.

For information about other scenarios, see [Scenarios for accessing a DB cluster in a VPC \(p. 1739\)](#).

Because your DB cluster needs to be available only to your Amazon EC2 instance, and not to the public internet, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The Amazon EC2 instance can connect to the DB cluster because it's hosted within the same VPC. However, the DB cluster is not available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to configure more than one Aurora DB instance.

To create a DB cluster that uses dual-stack mode, specify **Dual-stack mode** for the **Network type** setting. You can also modify a DB cluster with the same setting. For more information about creating a DB cluster, see [Creating an Amazon Aurora DB cluster \(p. 127\)](#). For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster \(p. 248\)](#).

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For more information about Amazon VPC, see [Amazon VPC Getting Started Guide](#) and [Amazon VPC User Guide](#).

## Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

### To create a VPC and subnets

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the upper-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the remaining **VPC settings**, set these values:
  - **Name tag auto-generation** – **tutorial-dual-stack**
  - **IPv4 CIDR block** – **10.0.0.0/16**
  - **IPv6 CIDR block** – **Amazon-provided IPv6 CIDR block**
  - **Tenancy** – **Default**
  - **Number of Availability Zones (AZs)** – **2**
  - **Customize AZs** – Keep the default values.
  - **Number of public subnet** – **2**
  - **Number of private subnets** – **2**
  - **Customize subnets CIDR blocks** – Keep the default values.
  - **NAT gateways (\$)** – **None**
  - **Egress only internet gateway** – **No**
  - **VPC endpoints** – **None**
  - **DNS options** – Keep the default values.

#### Note

Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

6. Choose **Create VPC**.

## Create a VPC security group for a public Amazon EC2 instance

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.

### To create a VPC security group

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
  - **Security group name:** **tutorial-dual-stack-securitygroup**
  - **Description:** **Tutorial Dual-Stack Security Group**

- **VPC:** Choose the VPC that you created earlier, for example: `vpc-identifier (tutorial-dual-stack-vpc)`
- 4. Add inbound rules to the security group.

- a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).

To determine your public IP address, in a different browser window or tab use the service at <https://checkip.amazonaws.com>. An example of an Internet Protocol version 4 (IPv4) address is 203.0.113.25/32. An example of an Internet Protocol version 6 (IPv6) address is 2001:DB8::/32.

If you are connecting through an internet service provider (ISP) or from behind your firewall without a static IP address, find out the range of IP addresses used by client computers.

**Warning**

If you use 0.0.0.0/0 for IPv4 or ::0 for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

- b. In the **Inbound rules** section, choose **Add rule**.
- c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address to allow to access your EC2 instance:
  - **Type: SSH**
  - **Source:** The IP address or range from step a. An example of an IPv4 IP address is **203.0.113.25/32**. An example of an IPv6 IP address is **2001:DB8::/32**.

5. Choose **Create security group** to create the security group.

Note the security group ID because you need it later in this tutorial.

## Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clusters in your VPC, add inbound rules to your VPC security group that allow traffic from your Amazon EC2 instance only.

### To create a VPC security group

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
  - **Security group name:** `tutorial-dual-stack-db-securitygroup`
  - **Description:** `Tutorial Dual-Stack DB Instance Security Group`
  - **VPC:** Choose the VPC that you created earlier, for example: `vpc-identifier (tutorial-dual-stack-vpc)`
4. Add inbound rules to the security group:
  - a. In the **Inbound rules** section, choose **Add rule**.
  - b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your EC2 instance to your DB cluster to store and retrieve data from your EC2 instance to your database.
    - **Type: MySQL**
    - **Source:** The IP address or range from step a. An example of an IPv4 IP address is **203.0.113.25/32**. An example of an IPv6 IP address is **2001:DB8::/32**.
    - **Port:** **3306**

- **Type:** MySQL/Aurora
  - **Source:** The identifier of the **tutorial-dual-stack-securitygroup** security group that you created previously in this tutorial, for example **sg-9edd5cfb**.
5. To create the security group, choose **Create security group**.

## Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters. To create a DB subnet group that is DUAL compatible, all subnets must be DUAL compatible. To be DUAL compatible, a subnet must have an IPv6 CIDR associated with it.

### To create a DB subnet group

1. Identify the private subnets for your database in the VPC.
  - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **Subnets**.
  - c. Note the subnet IDs of the subnets named **tutorial-dual-stack-subnet-private1-us-west-2a** and **tutorial-dual-stack-subnet-private2-us-west-2b**.

You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.
4. Choose **Create DB subnet group**.
5. On the **Create DB subnet group** page, set these values in **Subnet group details**:

- **Name:** **tutorial-dual-stack-db-subnet-group**
- **Description:** **Tutorial Dual-Stack DB Subnet Group**
- **VPC:** **tutorial-dual-stack-vpc (vpc-*identifier*)**

6. In the **Add subnets** section, choose values for the **Availability Zones** and **Subnets** options.

For this tutorial, choose **us-east-2a** and **us-east-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.

7. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

## Create an Amazon EC2 instance in dual-stack mode

To create an Amazon EC2 instance, follow the instructions in [Launch an instance using the new launch instance wizard](#) in the *Amazon EC2 User Guide for Linux Instances*.

On the **Configure Instance Details** page, set these values and keep the other values as their defaults:

- **Network** – Choose the VPC with both public and private subnets that you chose for the DB cluster, such as **vpc-*identifier* | tutorial-dual-stack-vpc** created in [Create a VPC with private and public subnets \(p. 1750\)](#).

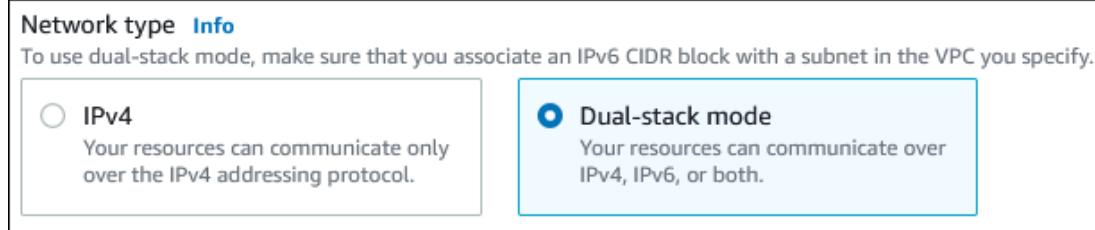

- **Subnet** – Choose an existing public subnet, such as **subnet-*identifier* | tutorial-dual-stack-subnet-public1-us-east-2a | us-east-2a** created in [Create a VPC security group for a public Amazon EC2 instance \(p. 1750\)](#).
- **Auto-assign Public IP** – Choose **Enable**.
- **Auto-assign IPv6 IP** – Choose **Enable**.
- **Firewall (security groups)** – Choose **Select an existing security group**.
- **Common security groups** – Choose choose an existing security group, such as the **tutorial-securitygroup** created in [Create a VPC security group for a public Amazon EC2 instance \(p. 1750\)](#). Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.

## Create a DB cluster in dual-stack mode

In this step, you create a DB cluster that runs in dual-stack mode.

### To create a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the console, choose the AWS Region where you want to create the DB cluster. This example uses the US East (Ohio) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, make sure that the **Standard create** option is chosen, and then choose the Aurora MySQL DB engine type.
6. In the **Connectivity** section, set these values:
  - **Network type** – Choose **Dual-stack mode**.

- **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (**vpc-*identifier***) created in [Create a VPC with private and public subnets \(p. 1750\)](#).

The VPC must have subnets in different Availability Zones.

- **DB subnet group** – Choose a DB subnet group for the VPC, such as **tutorial-dual-stack-db-subnet-group** created in [Create a DB subnet group \(p. 1752\)](#).
- **Public access** – Choose **No**.
- **VPC security group (firewall)** – Select **Choose existing**.
- **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as **tutorial-dual-stack-db-securitygroup** created in [Create a VPC security group for a private DB cluster \(p. 1751\)](#).

Remove other security groups, such as the default security group, by choosing the X associated with each.

- **Availability Zone** – Choose **us-west-2a**.

To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB cluster settings. For information about each setting, see [Settings for Aurora DB clusters \(p. 137\)](#).

## Connect to your Amazon EC2 instance and DB cluster

After you create your Amazon EC2 instance and DB cluster in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in [Connect to your Linux instance](#) in the *Amazon EC2 User Guide for Linux Instances*.

To connect to your DB cluster, follow the instructions in [Connecting to an Amazon Aurora DB cluster \(p. 207\)](#).

## Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, such as Amazon EC2 instances or DB clusters, you might need to delete these resources before you can delete the VPC. For more information, see [Delete your VPC](#) in the *Amazon VPC User Guide*.

### To delete a VPC and related resources

1. Delete the DB subnet group:
  - a. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
  - b. In the navigation pane, choose **Subnet groups**.
  - c. Select the DB subnet group to delete, such as **tutorial-db-subnet-group**.
  - d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID:
  - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **VPCs**.
  - c. In the list, identify the VPC you created, such as **tutorial-dual-stack-vpc**.
  - d. Note the **VPC ID** value of the VPC that you created. You need this VPC ID in subsequent steps.
3. Delete the security groups:
  - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **Security Groups**.
  - c. Select the security group for the Amazon RDS DB instance, such as **tutorial-dual-stack-db-securitygroup**.
  - d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
  - e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-dual-stack-securitygroup**.
  - f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
4. Delete the NAT gateway:
  - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **NAT Gateways**.

- c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.
  - d. For **Actions**, choose **Delete NAT gateway**.
  - e. On the confirmation page, enter **delete**, and then choose **Delete**.
5. Delete the VPC:
- a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **VPCs**.
  - c. Select the VPC that you want to delete, such as **tutorial-dual-stack-vpc**.
  - d. For **Actions**, choose **Delete VPC**.
- The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.
- e. On the confirmation page, enter **delete**, and then choose **Delete**.
6. Release the Elastic IP addresses:
- a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
  - b. Choose **EC2 Dashboard**, and then choose **Elastic IPs**.
  - c. Select the Elastic IP address that you want to release.
  - d. For **Actions**, choose **Release Elastic IP addresses**.
  - e. On the confirmation page, choose **Release**.

# Quotas and constraints for Amazon Aurora

Following, you can find a description of the resource quotas and naming constraints for Amazon Aurora.

## Topics

- [Quotas in Amazon Aurora \(p. 1756\)](#)
- [Naming constraints in Amazon Aurora \(p. 1759\)](#)
- [Amazon Aurora size limits \(p. 1759\)](#)

## Quotas in Amazon Aurora

Each AWS account has quotas, for each AWS Region, on the number of Amazon Aurora resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per AWS Region.

Name	Default	Adjust	Description
Authorizations per DB security group	Each supported Region: 20	No	Number of security group authorizations per DB security group
Custom engine versions	Each supported Region: 40	Yes	The maximum number of custom engine versions allowed in this account in the current Region
DB cluster parameter groups	Each supported Region: 50	No	The maximum number of DB cluster parameter groups
DB clusters	Each supported Region: 40	Yes	The maximum number of Aurora clusters allowed in this account in the current Region
DB instances	Each supported Region: 40	Yes	The maximum number of DB instances allowed in this account in the current Region
DB subnet groups	Each supported Region: 50	Yes	The maximum number of DB subnet groups
Data API HTTP request body size	Each supported Region: 4 Megabytes	No	The maximum size allowed for the HTTP request body.

Name	Default	Adjust	Description
Data API maximum concurrent cluster-secret pairs	Each supported Region: 30	No	The maximum number of unique pairs of Aurora Serverless DB clusters and secrets in concurrent Data API requests for the current account and AWS Region.
Data API maximum concurrent requests	Each supported Region: 500	No	The maximum number of Data API requests to an Aurora Serverless DB cluster that use the same secret and can be processed at the same time. Additional requests are queued and processed as in-process requests complete.
Data API maximum result set size	Each supported Region: 1 Megabytes	No	The maximum size of the database result set that can be returned by the Data API.
Data API maximum size of JSON response string	Each supported Region: 10 Megabytes	No	The maximum size of the simplified JSON response string returned by the RDS Data API.
Data API requests per second	Each supported Region: 1,000 per second	No	The maximum number of requests to the Data API per second allowed in this account in the current AWS Region.
Event subscriptions	Each supported Region: 20	Yes	The maximum number of event subscriptions
IAM roles per DB cluster	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB cluster
IAM roles per DB instance	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB instance
Manual DB cluster snapshots	Each supported Region: 100	Yes	The maximum number of manual DB cluster snapshots
Manual DB instance snapshots	Each supported Region: 100	Yes	The maximum number of manual DB instance snapshots
Option groups	Each supported Region: 20	Yes	The maximum number of option groups

Name	Default	Adjust	Description
Parameter groups	Each supported Region: 50	Yes	The maximum number of parameter groups
Proxies	Each supported Region: 20	Yes	The maximum number of proxies allowed in this account in the current AWS Region
Read replicas per master	Each supported Region: 5	Yes	The maximum number of read replicas per master
Reserved DB instances	Each supported Region: 40	Yes	The maximum number of reserved DB instances allowed in this account in the current AWS Region
Rules per security group	Each supported Region: 20	No	The maximum number of rules per DB security group
Security groups	Each supported Region: 25	Yes	The maximum number of DB security groups
Security groups (VPC)	Each supported Region: 5	No	The maximum number of DB security groups per Amazon VPC
Subnets per DB subnet group	Each supported Region: 20	No	The maximum number of subnets per DB subnet group
Tags per resource	Each supported Region: 50	No	The maximum number of tags per Amazon RDS resource
Total storage for all DB instances	Each supported Region: 100,000 Gigabytes	Yes	The maximum total storage (in GB) for all DB instances added together

### Note

The limits on total storage and number of read replicas don't apply to Aurora.

By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota.

If your application requires more DB instances, you can request additional DB instances by opening the [Service Quotas console](#). In the navigation pane, choose **AWS services**. Choose **Amazon Relational Database Service (Amazon RDS)**, choose a quota, and follow the directions to request a quota increase. For more information, see [Requesting a quota increase](#) in the [Service Quotas User Guide](#).

Backups managed by AWS Backup are considered manual DB cluster snapshots, but don't count toward the manual cluster snapshot quota. For information about AWS Backup, see the [AWS Backup Developer Guide](#).

If you use any of the Amazon RDS APIs and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error similar to the following: ClientError: An error occurred (ThrottlingException) when calling the **API\_name** operation: Rate exceeded. Reduce the number of calls per second. The quota is meant to cover most use cases. If higher limits are needed, request a quota

increase by contacting AWS Support. Open the [AWS Support Center](#) page, sign in if necessary, and choose **Create case**. Choose **Service limit increase**. Complete and submit the form.

**Note**

This quota can't be changed in the Amazon RDS Service Quotas console.

## Naming constraints in Amazon Aurora

The following table describes naming constraints in Amazon Aurora.

Resource or item	Constraints
DB cluster identifier	Identifiers have these naming constraints: <ul style="list-style-type: none"><li>Must contain 1–63 alphanumeric characters or hyphens.</li><li>First character must be a letter.</li><li>Can't end with a hyphen or contain two consecutive hyphens.</li><li>Must be unique for all DB instances per AWS account, per AWS Region.</li></ul>
Initial database name	Database name constraints differ between Aurora MySQL and PostgreSQL. For more information, see the available settings when creating each DB cluster.
Master user name	Master user name constraints differ for each database engine. For more information, see the available settings when creating each DB cluster.
Master password	The password for the database master user can include any printable ASCII character except /, ', ", @, or a space. Master password length constraints differ for each database engine. For more information, see the available settings when creating each DB cluster.
DB parameter group name	These names have these constraints: <ul style="list-style-type: none"><li>Must contain 1–255 alphanumeric characters.</li><li>First character must be a letter.</li><li>Hyphens are allowed, but the name cannot end with a hyphen or contain two consecutive hyphens.</li></ul>
DB subnet group name	These names have these constraints: <ul style="list-style-type: none"><li>Must contain 1–255 characters.</li><li>Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.</li></ul>

## Amazon Aurora size limits

### Storage size limits

An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB) for the following engine versions:

- Aurora MySQL versions 3.1 and higher (compatible with MySQL 8.0), 2.09 and higher (compatible with MySQL 5.7), and 1.23 and higher (compatible with MySQL 5.6)
- All Aurora PostgreSQL 14 and 13 versions; Aurora PostgreSQL 12.4, 11.7, 10.12, and 9.6.17 and higher minor versions of each of these versions.

For lower engine versions, the maximum size of an Aurora cluster volume is 64 TiB. For more information, see [How Aurora storage automatically resizes \(p. 67\)](#).

#### SQL table size limits

For Aurora MySQL, the maximum table size is 64 tebibytes (TiB). For an Aurora PostgreSQL DB cluster, the maximum table size is 32 tebibytes (TiB). We recommend that you follow table design best practices, such as partitioning of large tables.

To monitor the remaining storage space, you can use the `AuroraVolumeBytesLeftTotal` metric. For more information, see [Cluster-level metrics for Amazon Aurora \(p. 525\)](#).

# Troubleshooting for Amazon Aurora

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Amazon Aurora.

## Topics

- [Can't connect to Amazon RDS DB instance \(p. 1761\)](#)
- [Amazon RDS security issues \(p. 1763\)](#)
- [Resetting the DB instance owner password \(p. 1763\)](#)
- [Amazon RDS DB instance outage or reboot \(p. 1764\)](#)
- [Amazon RDS DB parameter changes not taking effect \(p. 1764\)](#)
- [Freeable memory issues in Amazon Aurora \(p. 1764\)](#)
- [Amazon Aurora MySQL out of memory issues \(p. 1765\)](#)
- [Amazon Aurora MySQL replication issues \(p. 1766\)](#)

For information about debugging problems using the Amazon RDS API, see [Troubleshooting applications on Aurora \(p. 1770\)](#).

## Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

### Note

When adding a new inbound rule, you can choose **My IP** for **Source** to allow access to the DB instance from the IP address detected in your browser.

For more information about setting up security groups, see [Provide access to the DB cluster in the VPC by creating a security group \(p. 90\)](#).

### Note

Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

To make the instance publicly accessible, modify it and choose **Yes** under **Public accessibility**. For more information, see [Hiding a DB cluster in a VPC from the internet \(p. 1735\)](#).

- **Port** – The port that you specified when you created the DB instance can't be used to send or receive communications due to your local firewall restrictions. To determine if your network allows the

specified port to be used for inbound and outbound communication, check with your network administrator.

- **Availability** – For a newly created DB instance, the DB instance has a status of *creating* until the DB instance is ready to use. When the state changes to *available*, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.
- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

### To configure an internet gateway for a subnet

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the name of the DB instance.
3. In the **Connectivity & security** tab, write down the values of the VPC ID under **VPC** and the subnet ID under **Subnets**.
4. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.
6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route Table** tab, verify that there is a route with 0.0.0.0/0 as the destination and the internet gateway for your VPC as the target.

If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (::/0) that points to the internet gateway. Otherwise, do the following:

- a. Choose the ID of the route table (rtb-xxxxxxx) to navigate to the route table.
- b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use 0.0.0.0/0 as the destination and the internet gateway as the target.  
For IPv6, choose **Add route**, use ::/0 as the destination and the internet gateway as the target.
- c. Choose **Save routes**.

Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

For more information, see [Working with a DB cluster in a VPC \(p. 1729\)](#).

## Testing a connection to a DB instance

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following (replace *DB-instance-endpoint* with the endpoint and *port* with the port of your DB instance).

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299
```

```
Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/vvr-data] succeeded!
```

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 819
Connecting To sg-postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com...Could not open
connection to the host, on port 819: Connect failed
```

If Telnet actions return success, your security group is properly configured.

**Note**

Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

## Troubleshooting connection authentication

If you can connect to your DB instance but you get authentication errors, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

## Amazon RDS security issues

To avoid security issues, never use your master AWS user name and password for a user account. Best practice is to use your master AWS account to create AWS Identity and Access Management (IAM) users and assign those to DB user accounts. You can also use your master account to create other user accounts, if necessary.

For more information on creating IAM users, see [Create an IAM user \(p. 87\)](#).

## Error message "failed to retrieve account attributes, certain console functions may be impaired."

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your IAM administrator needs to provide the necessary roles to your account. For more information, see [the IAM documentation](#).

## Resetting the DB instance owner password

If you get locked out of your DB cluster, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the AWS account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see [Master user account privileges \(p. 1723\)](#).

You can change the DB instance password by using the Amazon RDS console, the AWS CLI command [modify-db-instance](#), or by using the [ModifyDBInstance](#) API operation. For more information about modifying a DB instance in a DB cluster, see [Modify a DB instance in a DB cluster \(p. 249\)](#).

## Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you either manually reboot your DB instance or change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately or it can occur during the DB instance's maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0 and set **Apply Immediately** to **true**.
- You change the DB instance class, and **Apply Immediately** is set to **true**.

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and **Apply Immediately** is set to **false**.
- You change the DB instance class, and **Apply Immediately** is set to **false**.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

## Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console or explicitly calling the [RebootDBInstance](#) API operation (without failover, if the DB instance is in a Multi-AZ deployment). The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this might be calling [ModifyDBInstance](#) to change the DB instance class. For more information, see [Modifying parameters in a DB parameter group \(p. 231\)](#).

## Freeable memory issues in Amazon Aurora

*Freeable memory* is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can

use the temporary space that is normally used for buffering and caching. As previously mentioned, this temporary space is included in freeable memory.

You use the `FreeableMemory` metric in Amazon CloudWatch to monitor the freeable memory. For more information, see [Overview of monitoring metrics in Amazon Aurora \(p. 428\)](#).

If your DB instance consistently runs low on freeable memory or uses swap space, you might need to scale up to a larger DB instance class. For more information, see [Aurora DB instance classes \(p. 56\)](#).

You can also change the memory settings. For example, on Aurora MySQL, you might adjust the size of the `innodb_buffer_pool_size` parameter. This parameter is set by default to 75 percent of physical memory. For more MySQL troubleshooting tips, see [How can I troubleshoot low freeable memory in an Amazon RDS for MySQL database?](#)

For Aurora Serverless v2, `FreeableMemory` represents the amount of unused memory that's available when the Aurora Serverless v2 DB instance is scaled to its maximum capacity. You might have the instance scaled down to relatively low capacity, but it still reports a high value for `FreeableMemory`, because the instance can scale up. That memory isn't available right now, but you can get it if you need it.

For every Aurora capacity unit (ACU) that the current capacity is below the maximum capacity, `FreeableMemory` increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB instance is scaled up as high as it can.

If this metric approaches a value of 0, the DB instance has scaled up as much as it can and is nearing the limit of its available memory. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of 0 on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, the read-only part of the workload can be spread across more DB instances, reducing the memory usage on each reader DB instance. For more information, see [Important Amazon CloudWatch metrics for Aurora Serverless v2 \(p. 1539\)](#).

For Aurora Serverless v1, you can change the capacity range to use more ACUs. For more information, see [Modifying an Aurora Serverless v1 DB cluster \(p. 1570\)](#).

## Amazon Aurora MySQL out of memory issues

The Aurora MySQL `aurora_oom_response` instance-level parameter can enable the DB instance to monitor the system memory and estimate the memory consumed by various statements and connections. If the system runs low on memory, it can perform a list of actions to release that memory in an attempt to avoid out-of-memory (OOM) and database restart. The instance-level parameter takes a string of comma-separated actions that a DB instance should take when its memory is low. Valid actions include `print`, `tune`, `decline`, `kill_query`, or any combination of these. An empty string means that no action should be taken and effectively disables the feature.

### Note

This parameter only applies to Aurora MySQL version 1.18 and higher. It isn't used in Aurora MySQL version 2.

The following are usage examples for the `aurora_oom_response` parameter:

- `print` – Only prints the queries taking high amount of memory.
- `tune` – Tunes the internal table caches to release some memory back to the system.
- `decline` – Declines new queries once the instance is low on memory.
- `kill_query` – Ends the queries in descending order of memory consumption until the instance memory surfaces above the low threshold. Data definition language (DDL) statements aren't ended.
- `print, tune` – Performs actions described for both `print` and `tune`.

- `tune`, `decline`, `kill_query` – Performs the actions described for `tune`, `decline`, and `kill_query`.

For the db.t2.small DB instance class, the `aurora_oom_response` parameter is set to `print`, `tune` by default. For all other DB instance classes, the parameter value is empty by default (disabled).

## Amazon Aurora MySQL replication issues

Some MySQL replication issues also apply to Aurora MySQL. You can diagnose and correct these.

### Topics

- [Diagnosing and resolving lag between read replicas \(p. 1766\)](#)
- [Diagnosing and resolving a MySQL read replication failure \(p. 1767\)](#)
- [Replication stopped error \(p. 1768\)](#)

## Diagnosing and resolving lag between read replicas

After you create a MySQL read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS `AuroraBinlogReplicaLag` metric.

The `AuroraBinlogReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the MySQL `SHOW SLAVE STATUS` command. For more information, see [SHOW SLAVE STATUS](#). When the `AuroraBinlogReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `AuroraBinlogReplicaLag` metric returns -1, replication might not be active. To troubleshoot a replication error, see [Diagnosing and resolving a MySQL read replication failure \(p. 1767\)](#). A `AuroraBinlogReplicaLag` value of -1 can also mean that the `Seconds_Behind_Master` value can't be determined or is `NULL`.

### Note

Previous versions of Aurora MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using Aurora MySQL version 1 or 2, then use `SHOW SLAVE STATUS`. Use `SHOW REPLICA STATUS` for Aurora MySQL version 3 and higher.

The `AuroraBinlogReplicaLag` metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the `AuroraBinlogReplicaLag` metric again.

The MySQL read replication technology is asynchronous. Thus, you can expect occasional increases for the `BinLogDiskUsage` metric on the source DB instance and for the `AuroraBinlogReplicaLag` metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see [Replication implementation details](#) in the MySQL documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.

- Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.
- Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type` parameter to 0 in the DB parameter group for the DB instance. For more information on the query cache, see [Query cache configuration](#).
- Warm the buffer pool on the read replica for InnoDB for MySQL. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

For Linux, macOS, or Unix:

```
PROMPT> mysqldump \
-h <endpoint> \
--port=<port> \
-u=<username> \
-p <password> \
database_name table1 table2 > /dev/null
```

For Windows:

```
PROMPT> mysqldump ^
-h <endpoint> ^
--port=<port> ^
-u=<username> ^
-p <password> ^
database_name table1 table2 > /dev/null
```

## Diagnosing and resolving a MySQL read replication failure

Amazon RDS monitors the replication status of your read replicas and updates the **Replication State** field of the read replica instance to **Error** if replication stops for any reason. You can review the details of the associated error thrown by the MySQL engines by viewing the **Replication Error** field. Events that indicate the status of the read replica are also generated, including [RDS-EVENT-0045 \(p. 594\)](#), [RDS-EVENT-0046 \(p. 594\)](#), and [RDS-EVENT-0047 \(p. 594\)](#). For more information about events and subscribing to events, see [Working with Amazon RDS event notification \(p. 572\)](#). If a MySQL error message is returned, check the error in the [MySQL error message documentation](#).

Common situations that can cause replication errors include the following:

- The value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance.

The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. The `max_allowed_packet` parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. If the `max_allowed_packet` value for the source DB instance is larger than the `max_allowed_packet` value for the read replica, the replication process can throw an error and stop replication. The most common error is `packet bigger than 'max_allowed_packet' bytes`. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the `read_only` parameter set to `0` to create the indexes. If you're writing to tables on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

You can convert a MyISAM table to InnoDB with the following command:

```
alter table <schema>.<table_name> engine=innodb;
```

- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see [Determination of safe and unsafe statements in binary logging](#) in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in [Skipping the current replication error](#). Your Aurora MySQL DB instance must be running a version that includes the `mysql_rds_skip_repl_error` procedure. For more information, see [mysql\\_rds\\_skip\\_repl\\_error](#).
- If you encounter a binary log (binlog) position issue, you can change the replica replay position with the `mysql.rds_next_master_log` (Aurora MySQL version 1 and 2) or `mysql.rds_next_source_log` (Aurora MySQL version 3 and higher) command. Your Aurora MySQL DB instance must be running a version that supports this command to change the replica replay position. For version information, see [mysql\\_rds\\_next\\_master\\_log](#).
- If you encounter a temporary performance issue due to high DML load, you can set the `innodb_flush_log_at_trx_commit` parameter to `2` in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).
- You can delete the read replica and create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the **Replication State** changes to **replicating**. For more information, see [Troubleshooting a MySQL read replica problem](#).

## Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error due to binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the `mysql.rds_set_configuration` procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster, up to 2160 (90 days). The default for Aurora MySQL is 24 (1 day). The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

# Amazon RDS application programming interface (API) reference

In addition to the AWS Management Console, and the AWS Command Line Interface (AWS CLI), Amazon Relational Database Service (Amazon RDS) also provides an application programming interface (API). You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see [Actions](#).
- For an alphabetical list of data types, see [Data types](#).
- For a list of common query parameters, see [Common parameters](#).
- For descriptions of the error codes, see [Common errors](#).

For more information about the AWS CLI, see [AWS Command Line Interface reference for Amazon RDS](#).

## Topics

- [Using the Query API \(p. 1769\)](#)
- [Troubleshooting applications on Aurora \(p. 1770\)](#)

## Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see [Query requests](#) in the *Amazon EC2 API Reference*.

## Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named `Action`.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the `param.n` notation. Values of `n` are integers starting from 1.

For information about Amazon RDS regions and endpoints, go to [Amazon Relational Database Service \(RDS\)](#) in the Regions and Endpoints section of the *Amazon Web Services General Reference*.

## Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either AWS signature version 4 or signature version 2. For more information, see [Signature Version 4 signing process](#) and [Signature version 2 signing process](#).

# Troubleshooting applications on Aurora

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.

## Topics

- [Retrieving errors \(p. 1770\)](#)
- [Troubleshooting tips \(p. 1770\)](#)

For information about troubleshooting for Amazon RDS DB instances, see [Troubleshooting for Amazon Aurora \(p. 1761\)](#).

## Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an `Error` node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an `Error` node, as well as an easy way to retrieve the error code and message. The following code snippet uses Perl and the `XML::XPath` module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```
use XML::XPath;
my $xp = XML::XPath->new(xml =>$response);
if ( $xp->find("//Error") )
{print "There was an error processing your request:\n", " Error code: ",
$xp->findvalue("//Error[1]/Code"), "\n", " ",
$xp->findvalue("//Error[1]/Message"), "\n\n"; }
```

## Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API.

- Verify that Amazon RDS is operating normally in the AWS Region you are targeting by visiting <http://status.aws.amazon.com>.
- Check the structure of your request

Each Amazon RDS operation has a reference page in the *Amazon RDS API Reference*. Double-check that you are using parameters correctly. In order to give you ideas regarding what might be wrong, look at the sample requests or user scenarios to see if those examples are doing similar operations.

- Check AWS re:Post

Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to [AWS re:Post](#).

# Document history

**Current API version:** 2014-10-31

The following table describes important changes to the *Amazon Aurora User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed. For information about Amazon Relational Database Service (Amazon RDS), see the [Amazon Relational Database Service User Guide](#).

**Note**

Before August 31, 2018, Amazon Aurora was documented in the *Amazon Relational Database Service User Guide*. For earlier Aurora document history, see [Document history](#) in the *Amazon Relational Database Service User Guide*.

You can filter new Amazon Aurora features on the [What's New with Database?](#) page. For **Products**, choose **Amazon Aurora**. Then search using keywords such as **global database** or **Serverless**.

update-history-change	update-history-description	update-history-date
<a href="#">Amazon Aurora supports automatically setting up connectivity with an EC2 instance (p. 1771)</a>	When you create an Aurora DB cluster, you can use the AWS Management Console to set up connectivity between an Amazon Elastic Compute Cloud instance and the new DB cluster. For more information, see <a href="#">Configure automatic network connectivity with an EC2 instance</a> .	August 22, 2022
<a href="#">Amazon Aurora supports dual-stack mode (p. 1771)</a>	DB clusters can now run in dual-stack mode. In dual-stack mode, resources can communicate with the DB cluster over IPv4, IPv6, or both. For more information, see <a href="#">Amazon Aurora IP addressing</a> .	August 17, 2022
<a href="#">Amazon Aurora supports in-place upgrade for PostgreSQL-compatible Aurora Serverless v1 (p. 1771)</a>	You can perform an in-place upgrade for a PostgreSQL 10-compatible Aurora Serverless v1 cluster to change an existing cluster into a PostgreSQL 11-compatible Aurora Serverless v1 cluster. For the in-place upgrade procedure, see <a href="#">Modifying an Aurora Serverless v1 DB cluster</a> .	August 8, 2022
<a href="#">Performance Insights supports the Asia Pacific (Jakarta) Region (p. 1771)</a>	Formerly, you couldn't use Performance Insights in the Asia Pacific (Jakarta) Region. This restriction has been removed. For more information, see <a href="#">AWS Region support for Performance Insights</a> .	July 21, 2022
<a href="#">Amazon Aurora supports a new DB instance class (p. 1771)</a>	You can now use the db.r6i DB instance class for Aurora.	July 14, 2022

	PostgreSQL DB clusters. For more information, see <a href="#">DB instance classes</a> .	
<a href="#">RDS Performance Insights supports additional retention periods (p. 1771)</a>	Previously, Performance Insights offered only two retention periods: 7 days (default) or 2 years (731 days). Now, if you need to retain your performance data for longer than 7 days, you can specify from 1–24 months. For more information, see <a href="#">Pricing and data retention for Performance Insights</a> .	July 1, 2022
<a href="#">Amazon Aurora supports in-place upgrade for MySQL-compatible Aurora Serverless v1 (p. 1771)</a>	You can perform an in-place upgrade for a MySQL 5.6-compatible Aurora Serverless v1 cluster to change an existing cluster into a MySQL 5.7-compatible Aurora Serverless v1 cluster. For the in-place upgrade procedure, see <a href="#">Modifying an Aurora Serverless v1 DB cluster</a> .	June 16, 2022
<a href="#">Aurora supports turning on Amazon DevOps Guru in the RDS console (p. 1771)</a>	You can turn on DevOps Guru coverage for your Aurora databases from within the RDS console. For more information, see <a href="#">Setting up DevOps Guru for RDS</a> .	June 9, 2022
<a href="#">Amazon Aurora supports publishing events to encrypted Amazon SNS topics (p. 1771)</a>	Amazon Aurora can now publish events to Amazon Simple Notification Service (Amazon SNS) topics that have server-side encryption (SSE) enabled, for additional protection of events that carry sensitive data. For more information, see <a href="#">Subscribing to Amazon RDS event notification</a> .	June 1, 2022
<a href="#">Amazon RDS publishes usage metrics to Amazon CloudWatch (p. 1771)</a>	The AWS/Usage namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. For more information, see <a href="#">Amazon CloudWatch usage metrics for Amazon Aurora</a> .	April 28, 2022

<a href="#">Data API result sets in JSON format (p. 1771)</a>	An optional parameter for the <code>ExecuteStatement</code> function causes the query result set to be returned as a string in JSON format. The JSON result set is simple and convenient to transform into a data structure in your application's language. For more information, see <a href="#">Processing query results in JSON format</a> .	April 27, 2022
<a href="#">Amazon Aurora Serverless v2 is now generally available (p. 1771)</a>	Amazon Aurora Serverless v2 is generally available for all users. For more information, see <a href="#">Using Aurora Serverless v2</a> .	April 21, 2022
<a href="#">Aurora MySQL supports configurable cipher suites (p. 1771)</a>	With Aurora MySQL, you can now use configurable cipher suites to control the connection encryption that your database server accepts. For more information, see <a href="#">Configuring cipher suites for connections to Aurora MySQL DB clusters</a> .	April 15, 2022
<a href="#">Aurora PostgreSQL supports RDS Proxy with PostgreSQL 13 (p. 1771)</a>	You can now create an RDS Proxy with an Aurora PostgreSQL 13 DB cluster. For more information about RDS Proxy, see <a href="#">Using Amazon RDS Proxy</a> .	April 4, 2022
<a href="#">Release Notes for Aurora PostgreSQL (p. 1771)</a>	There is now a separate guide for the Amazon Aurora PostgreSQL release notes. For more information, see <a href="#">Release Notes for Aurora PostgreSQL</a> .	March 22, 2022
<a href="#">Release Notes for Aurora MySQL (p. 1771)</a>	There is now a separate guide for the Amazon Aurora MySQL release notes. For more information, see <a href="#">Release Notes for Aurora MySQL</a> .	March 22, 2022
<a href="#">Aurora PostgreSQL supports multi-major version upgrades (p. 1771)</a>	You can now perform version upgrades of Aurora PostgreSQL DB clusters across multiple major versions. For more information, see <a href="#">How to perform a major version upgrade</a> .	March 4, 2022

Aurora PostgreSQL supports configurable cipher suites (p. 1771)	With Aurora PostgreSQL versions 11.8 and higher, you can now use configurable cipher suites to control the connection encryption that your database server accepts. For information about using configurable cipher suites with Aurora PostgreSQL, see <a href="#">Configuring cipher suites for connections to Aurora PostgreSQL DB clusters</a> .	March 4, 2022
AWS JDBC Driver for MySQL generally available (p. 1771)	The AWS JDBC Driver for MySQL is a client driver designed for the high availability of Aurora MySQL. The AWS JDBC Driver for MySQL is now generally available. For more information, see <a href="#">Connecting with the Amazon Web Services JDBC Driver for MySQL</a> .	March 2, 2022
Aurora PostgreSQL 13.5 supports Babelfish for Aurora PostgreSQL 1.1.0 (p. 1771)	Aurora PostgreSQL 13.5 supports Babelfish 1.1.0. For a list of new features, see <a href="#">13.5</a> . For a list of features supported in each Babelfish release, see <a href="#">Supported functionality in Babelfish by version</a> . For usage information, see <a href="#">Working with Babelfish for Aurora PostgreSQL</a> .	February 28, 2022
Amazon Aurora supports Database Activity Streams in the Asia Pacific (Jakarta) Region (p. 1771)	For more information, see <a href="#">Support for AWS Regions for database activity streams</a> .	February 16, 2022
Performance Insights supports new API operations (p. 1771)	Performance Insights now supports the following API operations: <code>GetResourceMetadata</code> , <code>ListAvailableResourceDimensions</code> , and <code>ListAvailableResourceMetrics</code> . For more information, see <a href="#">Retrieving metrics with the Performance Insights API</a> in this manual and the <a href="#">Amazon RDS Performance Insights API Reference</a> .	January 12, 2022
Amazon RDS Proxy supports events (p. 1771)	RDS Proxy now generates events that you can subscribe to and view in CloudWatch Events or configure to send to Amazon EventBridge. For more information, see <a href="#">Working with RDS Proxy events</a> .	January 11, 2022

RDS Proxy available in additional AWS Regions (p. 1771)	RDS Proxy is now available in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Osaka), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo). For more information about RDS Proxy, see <a href="#">Using Amazon RDS Proxy</a> .	January 5, 2022
Amazon Aurora available in the Asia Pacific (Jakarta) Region (p. 1771)	Aurora is now available in the Asia Pacific (Jakarta) Region. For more information, see <a href="#">Regions and Availability Zones</a> .	December 13, 2021
DevOps Guru for Amazon RDS provides detailed insights and recommendations for Amazon Aurora (p. 1771)	DevOps Guru for RDS mines Performance Insights for performance-related data. Using this data, the service analyzes the performance of your Amazon Aurora DB instances and can help you resolve performance issues. To learn more, see <a href="#">Analyzing performance anomalies with DevOps Guru for RDS</a> in this guide and see <a href="#">Overview of DevOps Guru for RDS</a> in the <a href="#">Amazon DevOps Guru User Guide</a> .	December 1, 2021
Aurora PostgreSQL supports RDS Proxy with PostgreSQL 12 (p. 1771)	You can now create an RDS Proxy with an Aurora PostgreSQL 12 database cluster. For more information about RDS Proxy, see <a href="#">Using Amazon RDS Proxy</a> .	November 22, 2021
Aurora supports AWS Graviton2 instance classes for Database Activity Streams (p. 1771)	You can use database activity streams with the db.r6g instance class for Aurora MySQL and Aurora PostgreSQL. For more information, see <a href="#">Supported DB instance classes</a> .	November 3, 2021
Amazon Aurora support for cross-account AWS KMS keys (p. 1771)	You can use a KMS key from a different AWS account for encryption when exporting DB snapshots to Amazon S3. For more information, see <a href="#">Exporting DB snapshot data to Amazon S3</a> .	November 3, 2021

<a href="#">Amazon Aurora supports Babelfish for Aurora PostgreSQL (p. 1771)</a>	Babelfish for Aurora PostgreSQL extends your Amazon Aurora PostgreSQL-Compatible Edition database with the ability to accept database connections from Microsoft SQL Server clients. For more information, see <a href="#">Working with Babelfish for Aurora PostgreSQL</a> .	October 28, 2021
<a href="#">Aurora Serverless v1 can require SSL for connections (p. 1771)</a>	The Aurora cluster parameters <code>force_ssl</code> for PostgreSQL and <code>require_secure_transport</code> for MySQL are supported now for Aurora Serverless v1. For more information, see <a href="#">Using TLS/SSL with Aurora Serverless v1</a> .	October 26, 2021
<a href="#">Amazon Aurora supports Performance Insights in additional AWS Regions (p. 1771)</a>	Performance Insights is available in the Middle East (Bahrain), Africa (Cape Town), Europe (Milan), and Asia Pacific (Osaka) Regions. For more information, see <a href="#">AWS Region support for Performance Insights</a> .	October 5, 2021
<a href="#">Configurable autoscaling timeout for Aurora Serverless v1 (p. 1771)</a>	You can choose how long Aurora Serverless v1 waits to find an autoscaling point. If no autoscaling point is found during that period, Aurora Serverless v1 cancels the scaling event or forces the capacity change, depending on the timeout action that you selected. For more information, see <a href="#">Autoscaling for Aurora Serverless v1</a> .	September 10, 2021
<a href="#">Aurora supports X2g and T4g instance classes (p. 1771)</a>	Both Aurora MySQL and Aurora PostgreSQL can now use X2g and T4g instance classes. The instance classes that you can use depend on the version of Aurora MySQL or Aurora PostgreSQL. For information about supported instance types, see <a href="#">DB instance classes</a> .	September 10, 2021
<a href="#">Amazon RDS supports RDS Proxy in a shared VPC (p. 1771)</a>	You can now create an RDS Proxy in a shared virtual private cloud (VPC). For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the <a href="#">Amazon RDS User Guide</a> or the <a href="#">Aurora User Guide</a> .	August 6, 2021

Aurora version policy page (p. 1771)	The <i>Amazon Aurora User Guide</i> now includes a section with general information about Aurora versions and associated policies. For details, see <a href="#">Amazon Aurora versions</a> .	July 14, 2021
Exclude Data API events from an AWS CloudTrail trail (p. 1771)	You can exclude Data API events from a CloudTrail trail. For more information, see <a href="#">Excluding Data API events from an AWS CloudTrail trail</a> .	July 2, 2021
Amazon Aurora PostgreSQL-Compatible Edition supports additional extensions (p. 1771)	Newly supported extensions include pg_bigm, pg_cron, pg_partman, and pg_proctab. For more information, see <a href="#">Extension versions for Amazon Aurora PostgreSQL-Compatible Edition</a> .	June 17, 2021
Cloning for Aurora Serverless clusters (p. 1771)	You can now create cloned clusters that are Aurora Serverless. For information about cloning, see <a href="#">Cloning a volume for an Aurora DB cluster</a> .	June 16, 2021
Aurora global databases available in China (Beijing) and China (Ningxia) Regions (p. 1771)	You can now create Aurora global databases in the China (Beijing) and China (Ningxia) Regions. For information about Aurora global databases, see <a href="#">Working with Amazon Aurora global databases</a> .	May 19, 2021
FIPS 140-2 support for Data API (p. 1771)	The Data API supports the Federal Information Processing Standard Publication 140-2 (FIPS 140-2) for SSL/TLS connections. For more information, see <a href="#">Data API availability</a> .	May 14, 2021
AWS JDBC Driver for PostgreSQL (preview) (p. 1771)	The AWS JDBC Driver for PostgreSQL, now available in preview, is a client driver designed for the high availability of Aurora PostgreSQL. For more information, see <a href="#">Connecting with the Amazon Web Services JDBC Driver for PostgreSQL (preview)</a> .	April 27, 2021
The Data API available in additional AWS Regions (p. 1771)	The Data API is now available in the Asia Pacific (Seoul) and Canada (Central) Regions. For more information, see <a href="#">Availability of the Data API</a> .	April 9, 2021

Amazon Aurora supports the Graviton2 DB instance classes (p. 1771)	You can now use the Graviton2 DB instance classes db.r6g.x to create DB clusters running MySQL or PostgreSQL. For more information, see <a href="#">DB instance class types</a> .	March 12, 2021
RDS Proxy endpoint enhancements (p. 1771)	You can create additional endpoints associated with each RDS proxy. Creating an endpoint in a different VPC enables cross-VPC access for the proxy. Proxies for Aurora MySQL clusters can also have read-only endpoints. These reader endpoints connect to reader DB instances in the clusters and can improve read scalability and availability for query-intensive applications. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the <a href="#">Amazon RDS User Guide</a> or the <a href="#">Aurora user guide</a> .	March 8, 2021
Amazon Aurora available in the Asia Pacific (Osaka) Region (p. 1771)	Aurora is now available in the Asia Pacific (Osaka) Region. For more information, see <a href="#">Regions and Availability Zones</a> .	March 1, 2021
Aurora PostgreSQL supports enabling both IAM and Kerberos authentication on the same DB cluster (p. 1771)	Aurora PostgreSQL now supports enabling both IAM authentication and Kerberos authentication on the same DB cluster. For more information, see <a href="#">Database authentication with Amazon Aurora</a> .	February 24, 2021
Aurora global database now supports managed planned failover (p. 1771)	Aurora global database now supports managed planned failover, allowing you to more easily change the primary AWS Region of your Aurora global database. You can use managed planned failover with healthy Aurora global databases only. To learn more, see <a href="#">Disaster recovery and Amazon Aurora global databases</a> . For reference information, see <a href="#">FailoverGlobalCluster</a> in the <a href="#">Amazon RDS API Reference</a> .	February 11, 2021

<a href="#">Data API for Aurora Serverless now supports more data types (p. 1771)</a>	With the Data API for Aurora Serverless, you can now use <code>UUID</code> and <code>JSON</code> data types as input to your database. Also with the Data API for Aurora Serverless, you can now have a <code>LONG</code> type value returned from your database as a <code>STRING</code> value. To learn more, see <a href="#">Calling the Data API</a> . For reference information about supported data types, see <a href="#">SqlParameter</a> in the <i>Amazon RDS Data Service API Reference</i> .	February 2, 2021
<a href="#">Aurora PostgreSQL supports major version upgrades to PostgreSQL 12 (p. 1771)</a>	With Aurora PostgreSQL, you can now upgrade the DB engine to major version 12. For more information, see <a href="#">Upgrading the PostgreSQL DB engine for Aurora PostgreSQL</a> .	January 28, 2021
<a href="#">Aurora MySQL supports in-place upgrade (p. 1771)</a>	You can upgrade your Aurora MySQL 1.x cluster to Aurora MySQL 2.x, preserving the DB instances, endpoints, and so on of the original cluster. This in-place upgrade technique avoids the inconvenience of setting up a whole new cluster by restoring a snapshot. It also avoids the overhead of copying all your table data into a new cluster. For more information, see <a href="#">Upgrading the major version of an Aurora MySQL DB cluster from 1.x to 2.x</a> .	January 11, 2021
<a href="#">AWS JDBC Driver for MySQL (preview) (p. 1771)</a>	The AWS JDBC Driver for MySQL, now available in preview, is a client driver designed for the high availability of Aurora MySQL. For more information, see <a href="#">Connecting with the Amazon Web Services JDBC Driver for MySQL (preview)</a> .	January 7, 2021
<a href="#">Aurora supports database activity streams on secondary clusters of a global database (p. 1771)</a>	You can start a database activity stream on a primary or secondary cluster of Aurora PostgreSQL or Aurora MySQL. For supported engine versions, see <a href="#">Limitations of Aurora global databases</a> .	December 22, 2020

<a href="#">Multi-master clusters with 4 DB instances (p. 1771)</a>	The maximum number of DB instances in an Aurora MySQL multi-master cluster is now four. Formerly, the maximum was two DB instances. For more information, see <a href="#">Working with Aurora Multi-Master Clusters</a> .	December 17, 2020
<a href="#">Aurora PostgreSQL supports AWS Lambda functions (p. 1771)</a>	You can now invoke AWS Lambda function for your Aurora PostgreSQL DB clusters. For more information, see <a href="#">Invoking a Lambda function from an Aurora PostgreSQL DB cluster</a> .	December 11, 2020
<a href="#">Amazon Aurora supports the Graviton2 DB instance classes in preview (p. 1771)</a>	You can now use the Graviton2 DB instance classes db.r6g.x in preview to create DB clusters running MySQL or PostgreSQL. For more information, see <a href="#">DB instance class types</a> .	December 11, 2020
<a href="#">Amazon Aurora Serverless v2 is now available in preview. (p. 1771)</a>	Amazon Aurora Serverless v2 is available in preview. To work with Amazon Aurora Serverless v2, apply for access. For more information, see the <a href="#">Aurora Serverless v2 page</a> .	December 1, 2020
<a href="#">Aurora PostgreSQL is now available for Aurora Serverless in more AWS Regions. (p. 1771)</a>	Aurora PostgreSQL is now available for Aurora Serverless in more AWS Regions. You can now choose to run Aurora PostgreSQL Serverless v1 in the same AWS Regions that offer Aurora MySQL Serverless v1. Additional AWS Regions with Aurora Serverless support include US West (N. California), Asia Pacific (Singapore) Asia Pacific (Sydney) Asia Pacific (Seoul) Asia Pacific (Mumbai) Canada (Central) Europe (London) and Europe (Paris). For a list of all Regions and supported Aurora DB engines for Aurora Serverless, see <a href="#">Aurora Serverless</a> . Amazon RDS Data API for Aurora Serverless is also now available in these same AWS Regions. For a list of all Regions with support for the Data API for Aurora Serverless, see <a href="#">Data API for Aurora Serverless</a>	November 24, 2020

Amazon RDS Performance Insights introduces new dimensions (p. 1771)	You can group database load according to the dimension groups for database, application (PostgreSQL), and session type (PostgreSQL). Amazon RDS also supports the dimensions db.name, db.application.name (PostgreSQL), and db.session_type.name (PostgreSQL). For more information, see <a href="#">Top load table</a> .	November 24, 2020
Aurora Serverless supports Aurora PostgreSQL version 10.12 (p. 1771)	Aurora PostgreSQL for Aurora Serverless has been upgraded to Aurora PostgreSQL version 10.12 throughout the AWS Regions where Aurora PostgreSQL for Aurora Serverless is supported. For more information, see <a href="#">Aurora Serverless</a> .	November 4, 2020
The Data API now supports tag-based authorization (p. 1771)	The Data API supports tag-based authorization. If you've labeled your RDS cluster resources with tags, you can use these tags in your policy statements to control access through the Data API. For more information, see <a href="#">Authorizing access to the Data API</a> .	October 27, 2020
Amazon Aurora extends support for exporting snapshots to Amazon S3 (p. 1771)	You can now export DB snapshot data to Amazon S3 in all commercial AWS Regions. For more information, see <a href="#">Exporting DB snapshot data to Amazon S3</a> .	October 22, 2020
Aurora global database supports cloning (p. 1771)	You can now create clones of the primary and secondary DB clusters of your Aurora global databases. You can do so by using the AWS Management Console and choosing the <b>Create clone</b> menu option. You can also use the AWS CLI and run the <code>restore-db-cluster-to-point-in-time</code> command with the <code>--restore-type copy-on-write</code> option. Using the AWS Management Console or the AWS CLI, you can also clone DB clusters from your Aurora global databases across AWS accounts. For more information about cloning, see <a href="#">Cloning an Aurora DB cluster volume</a> .	October 19, 2020

Amazon Aurora supports dynamic resizing for the cluster volume (p. 1771)	Starting with Aurora MySQL 1.23 and 2.09, and Aurora PostgreSQL 3.3.0 and Aurora PostgreSQL 2.6.0, Aurora reduces the size of the cluster volume after you remove data through operations such as <code>DROP TABLE</code> . To take advantage of this enhancement, upgrade to one of the appropriate versions depending on the database engine that your cluster uses. For information about this feature and how to check used and available storage space for an Aurora cluster, see <a href="#">Managing Performance and Scaling for Aurora DB Clusters</a> .	October 13, 2020
Amazon Aurora supports volume sizes up to 128 TiB (p. 1771)	New and existing Aurora cluster volumes can now grow to a maximum size of 128 tebibytes (TiB). For more information, see <a href="#">How Aurora storage grows</a> .	September 22, 2020
Aurora PostgreSQL supports the db.r5 and db.t3 DB instance classes in the China (Ningxia) Region (p. 1771)	You can now create Aurora PostgreSQL DB clusters in the China (Ningxia) Region that use the db.r5 and db.t3 DB instance classes. For more information, see <a href="#">DB instance classes</a> .	September 3, 2020

[Aurora parallel query enhancements \(p. 1771\)](#)

Starting with Aurora MySQL 2.09 and 1.23, you can take advantage of enhancements to the parallel query feature. Creating a parallel query cluster no longer requires a special engine mode. You can now turn parallel query on and off using the `aurora_parallel_query` configuration option for any provisioned cluster that's running a compatible Aurora MySQL version. You can upgrade an existing cluster to a compatible Aurora MySQL version and use parallel query, instead of creating a new cluster and importing data into it. You can use Performance Insights for parallel query clusters. You can stop and start parallel query clusters. You can create Aurora parallel query clusters that are compatible with MySQL 5.7. Parallel query works for tables that use the `DYNAMIC` row format. Parallel query clusters can use AWS Identity and Access Management (IAM) authentication. Reader DB instances in parallel query clusters can take advantage of the `READ COMMITTED` isolation level. You can also now create parallel query clusters in additional AWS Regions. For more information about the parallel query feature and these enhancements, see [Working with parallel query for Aurora MySQL](#).

September 2, 2020

[Changes to Aurora MySQL parameter binlog\\_rows\\_query\\_log\\_events \(p. 210\)](#)

You can now change the value of the Aurora MySQL configuration parameter `binlog_rows_query_log_events`. Formerly, this parameter wasn't modifiable.

August 26, 2020

<a href="#">Support for automatic minor version upgrades for Aurora MySQL (p. 1771)</a>	With Aurora MySQL, the setting <b>Enable auto minor version upgrade</b> now takes effect when you specify it for an Aurora MySQL DB cluster. When you enable auto minor version upgrade, Aurora automatically upgrades to new minor versions as they are released. The automatic upgrades occur during the maintenance window for the database. For Aurora MySQL, this feature applies only to Aurora MySQL version 2, which is compatible with MySQL 5.7. Initially, the automatic upgrade procedure brings Aurora MySQL DB clusters to version 2.07.2. For more information about how this feature works with Aurora MySQL, see <a href="#">Database Upgrades and Patches for Amazon Aurora MySQL</a> .	August 3, 2020
<a href="#">Aurora PostgreSQL supports major version upgrades to PostgreSQL version 11 (p. 1771)</a>	With Aurora PostgreSQL, you can now upgrade the DB engine to major version 11. For more information, see <a href="#">Upgrading the PostgreSQL DB engine for Aurora PostgreSQL</a> .	July 28, 2020
<a href="#">Amazon Aurora supports AWS PrivateLink (p. 1771)</a>	Amazon Aurora now supports creating Amazon VPC endpoints for Amazon RDS API calls to keep traffic between applications and Aurora in the AWS network. For more information, see <a href="#">Amazon Aurora and interface VPC endpoints (AWS PrivateLink)</a> .	July 9, 2020
<a href="#">RDS Proxy generally available (p. 1771)</a>	RDS Proxy is now generally available. You can use RDS Proxy with RDS for MySQL, Aurora MySQL, RDS for PostgreSQL, and Aurora PostgreSQL for production workloads. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the <a href="#">Amazon RDS User Guide</a> or the Aurora user guide.	June 30, 2020

Aurora global database write forwarding (p. 1771)	You can now enable write capability on secondary clusters in a global database. With write forwarding, you issue DML statements on a secondary cluster, Aurora forwards the write to the primary cluster, and the updated data is replicated to all the secondary clusters. For more information, see <a href="#">Write forwarding for secondary AWS Regions with an Aurora global database</a> .	June 18, 2020
Aurora supports integration with AWS Backup (p. 1771)	You can use AWS Backup to manage backups of Aurora DB clusters. For more information, see <a href="#">Overview of backing up and restoring an Aurora DB cluster</a> .	June 10, 2020
Aurora PostgreSQL supports db.t3.large DB instance classes (p. 1771)	You can now create Aurora PostgreSQL DB clusters that use the db.t3.large DB instance classes. For more information, see <a href="#">DB instance classes</a> .	June 5, 2020
Aurora global database supports PostgreSQL version 11.7 and managed recovery point objective (RPO) (p. 1771)	You can now create Aurora global databases for the PostgreSQL database engine version 11.7. You can also manage how a PostgreSQL global database recovers from a failure using a recovery point objective (RPO). For more information, see <a href="#">Cross-Region Disaster Recovery for Aurora global databases</a> .	June 4, 2020
Aurora MySQL supports database monitoring with database activity streams (p. 1771)	Aurora MySQL now includes database activity streams, which provide a near-real-time data stream of the database activity in your relational database. For more information, see <a href="#">Using database activity streams</a> .	June 2, 2020
The query editor available in additional AWS Regions (p. 1771)	The query editor for Aurora Serverless is now available in additional AWS Regions. For more information, see <a href="#">Availability of the query editor</a> .	May 28, 2020
The Data API available in additional AWS Regions (p. 1771)	The Data API is now available in additional AWS Regions. For more information, see <a href="#">Availability of the Data API</a> .	May 28, 2020

RDS Proxy available in Canada (Central) Region (p. 1771)	You can now use the RDS Proxy preview in the Canada (Central) Region. For more information about RDS Proxy, see <a href="#">Managing connections with Amazon RDS proxy (preview)</a> .	May 28, 2020
Aurora global database and cross-Region read replicas (p. 1771)	For an Aurora global database, you can now create an Aurora MySQL cross-Region read replica from the primary cluster in the same region as a secondary cluster. For more information about Aurora Global Database and cross-Region read replicas, see <a href="#">Working with Amazon Aurora global database and Replicating Amazon Aurora MySQL DB</a> .	May 18, 2020
RDS Proxy available in more AWS Regions (p. 1771)	You can now use the RDS Proxy preview in the US West (N. California) Region, the Europe (London) Region, the Europe (Frankfurt) Region, the Asia Pacific (Seoul) Region, the Asia Pacific (Mumbai) Region, the Asia Pacific (Singapore) Region, and the Asia Pacific (Sydney) Region. For more information about RDS Proxy, see <a href="#">Managing connections with Amazon RDS proxy (preview)</a> .	May 13, 2020
Aurora PostgreSQL-Compatible Edition supports on-premises or self-hosted Microsoft active directory (p. 1771)	You can now use an on-premises or self-hosted Active Directory for Kerberos authentication of users when they connect to your Aurora PostgreSQL DB clusters. For more information, see <a href="#">Using Kerberos authentication with Aurora PostgreSQL</a> .	May 7, 2020
Aurora MySQL multi-master clusters available in more AWS Regions (p. 1771)	You can now create Aurora multi-master clusters in the Asia Pacific (Seoul) Region, the Asia Pacific (Tokyo) Region, the Asia Pacific (Mumbai) Region, and the Europe (Frankfurt) Region. For more information about multi-master clusters, see <a href="#">Working with Aurora multi-master clusters</a> .	May 7, 2020

<a href="#">Performance Insights supports analyzing statistics of running Aurora MySQL queries (p. 1771)</a>	You can now analyze statistics of running queries with Performance Insights for Aurora MySQL DB instances. For more information, see <a href="#">Analyzing statistics of running queries</a> .	May 5, 2020
<a href="#">Java client library for Data API generally available (p. 1771)</a>	The Java client library for the Data API is now generally available. You can download and use a Java client library for Data API. It enables you to map your client-side classes to requests and responses of the Data API. For more information, see <a href="#">Using the Java client library for Data API</a> .	April 30, 2020
<a href="#">Amazon Aurora available in the Europe (Milan) Region (p. 1771)</a>	Aurora is now available in the Europe (Milan) Region. For more information, see <a href="#">Regions and Availability Zones</a> .	April 28, 2020
<a href="#">Amazon Aurora available in the Europe (Milan) Region (p. 1771)</a>	Aurora is now available in the Europe (Milan) Region. For more information, see <a href="#">Regions and Availability Zones</a> .	April 27, 2020
<a href="#">Amazon Aurora available in the Africa (Cape Town) Region (p. 1771)</a>	Aurora is now available in the Africa (Cape Town) Region. For more information, see <a href="#">Regions and Availability Zones</a> .	April 22, 2020
<a href="#">Aurora PostgreSQL now supports db.r5.16xlarge and db.r5.8xlarge DB instance classes (p. 1771)</a>	You can now create Aurora PostgreSQL DB clusters running PostgreSQL that use the db.r5.16xlarge and db.r5.8xlarge DB instance classes. For more information, see <a href="#">Hardware specifications for DB instance classes for Aurora</a> .	April 8, 2020
<a href="#">Amazon RDS proxy for PostgreSQL (p. 1771)</a>	Amazon RDS Proxy is now available for PostgreSQL. You can use RDS Proxy to reduce the overhead of connection management on your cluster and also the chance of "too many connections" errors. The RDS Proxy is currently in public preview for PostgreSQL. For more information, see <a href="#">Managing connections with Amazon RDS proxy (preview)</a> .	April 8, 2020

Aurora global databases now support Aurora PostgreSQL (p. 1771)	You can now create Aurora global databases for the PostgreSQL database engine. An Aurora global database spans multiple AWS Regions, enabling low latency global reads and disaster recovery from region-wide outages. For more information, see <a href="#">Working with Amazon Aurora global database</a> .	March 10, 2020
Support for major version upgrades for Aurora PostgreSQL (p. 1771)	With Aurora PostgreSQL, you can now upgrade the DB engine to a major version. By doing so, you can skip ahead to a newer major version when you upgrade select PostgreSQL engine versions. For more information, see <a href="#">Upgrading the PostgreSQL DB engine for Aurora PostgreSQL</a> .	March 4, 2020
Aurora PostgreSQL supports Kerberos authentication (p. 1771)	You can now use Kerberos authentication to authenticate users when they connect to your Aurora PostgreSQL DB clusters. For more information, see <a href="#">Using Kerberos authentication with Aurora PostgreSQL</a> .	February 28, 2020
The Data API supports AWS PrivateLink (p. 1771)	The Data API now supports creating Amazon VPC endpoints for Data API calls to keep traffic between applications and the Data API in the AWS network. For more information, see <a href="#">Creating an Amazon VPC endpoint (AWS PrivateLink) for the Data API</a> .	February 6, 2020
Aurora machine learning support in Aurora PostgreSQL (p. 1771)	The <code>aws_ml</code> Aurora PostgreSQL extension provides functions you use in your database queries to call Amazon Comprehend for sentiment analysis and SageMaker to run your own machine learning models. For more information, see <a href="#">Using machine learning (ML) capabilities with Aurora</a> .	February 5, 2020

Aurora PostgreSQL supports exporting data to Amazon S3 (p. 1771)	You can query data from an Aurora PostgreSQL DB cluster and export it directly into files stored in an Amazon S3 bucket. For more information, see <a href="#">Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3</a> .	February 5, 2020
Support for exporting DB snapshot data to Amazon S3 (p. 1771)	Amazon Aurora supports exporting DB snapshot data to Amazon S3 for MySQL and PostgreSQL. For more information, see <a href="#">Exporting DB snapshot data to Amazon S3</a> .	January 9, 2020
Aurora MySQL release notes in document history (p. 1771)	This section now includes history entries for Aurora MySQL-Compatible Edition release notes for versions released after August 31, 2018. For the full release notes for a specific version, choose the link in the first column of the history entry.	December 13, 2019
Amazon RDS proxy (p. 1771)	You can reduce the overhead of connection management on your cluster, and reduce the chance of "too many connections" errors, by using the Amazon RDS Proxy. You associate each proxy with an RDS DB instance or Aurora DB cluster. Then you use the proxy endpoint in the connection string for your application. The Amazon RDS Proxy is currently in a public preview state. It supports the Aurora MySQL database engine. For more information, see <a href="#">Managing connections with Amazon RDS proxy (preview)</a> .	December 3, 2019
Data API for Aurora Serverless v1 supports data type mapping hints (p. 1771)	You can now use a hint to instruct the Data API for Aurora Serverless v1 to send a String value to the database as a different type. For more information, see <a href="#">Calling the data API</a> .	November 26, 2019

<a href="#">Data API for Aurora Serverless v1 supports a Java client library (preview) (p. 1771)</a>	You can download and use a Java client library for Data API. It enables you to map your client-side classes to requests and responses of the Data API. For more information, see <a href="#">Using the Java client library for Data API</a> .	November 26, 2019
<a href="#">Aurora PostgreSQL is FedRAMP HIGH eligible (p. 1771)</a>	Aurora PostgreSQL is FedRAMP HIGH eligible. For details about AWS and compliance efforts, see <a href="#">AWS services in scope by compliance program</a> .	November 26, 2019
<a href="#">READ COMMITTED isolation level enabled for Amazon Aurora MySQL replicas (p. 1771)</a>	You can now enable the <code>READ COMMITTED</code> isolation level on Aurora MySQL Replicas. Doing so requires enabling the <code>aurora_read_replica_read_committed_isolation_enabled</code> configuration setting at the session level. Using the <code>READ COMMITTED</code> isolation level for long-running queries on OLTP clusters can help address issues with history list length. Before enabling this setting, be sure to understand how the isolation behavior on Aurora Replicas differs from the usual MySQL implementation of <code>READ COMMITTED</code> . For more information, see <a href="#">Aurora MySQL isolation levels</a> .	November 25, 2019
<a href="#">Performance Insights supports analyzing statistics of running Aurora PostgreSQL queries (p. 1771)</a>	You can now analyze statistics of running queries with Performance Insights for Aurora PostgreSQL DB instances. For more information, see <a href="#">Analyzing statistics of running queries</a> .	November 25, 2019
<a href="#">More clusters in an Aurora global database (p. 1771)</a>	You can now add multiple secondary regions to an Aurora global database. You can take advantage of low latency global reads and disaster recovery across a wider geographic area. For more information about Aurora global databases, see <a href="#">Working with Amazon Aurora global databases</a> .	November 25, 2019

Aurora machine learning support in Aurora MySQL (p. 1771)	In Aurora MySQL 2.07 and higher, you can call Amazon Comprehend for sentiment analysis and SageMaker for a wide variety of machine learning algorithms. You use the results directly in your database application by embedding calls to stored functions in your queries. For more information, see <a href="#">Using machine learning (ML) capabilities with Aurora</a> .	November 25, 2019
Aurora global database no longer requires engine mode setting (p. 1771)	You no longer need to specify <code>--engine-mode=global</code> when creating a cluster that is intended to be part of an Aurora global database. All Aurora clusters that meet the compatibility requirements are eligible to be part of a global database. For example, the cluster currently must use Aurora MySQL version 1 with MySQL 5.6 compatibility. For information about Aurora global databases, see <a href="#">Working with Amazon Aurora global databases</a> .	November 25, 2019
Aurora global database is available for Aurora MySQL version 2 (p. 1771)	Starting in Aurora MySQL 2.07, you can create an Aurora global database with MySQL 5.7 compatibility. You don't need to specify the <code>global</code> engine mode for the primary or secondary clusters. You can add any new provisioned cluster with Aurora MySQL 2.07 or higher to an Aurora Global Database. For information about Aurora Global Database, see <a href="#">Working with Amazon Aurora global database</a> .	November 25, 2019
Aurora MySQL hot row contention optimization available without lab mode (p. 1771)	The hot row contention optimization is now generally available for Aurora MySQL and does not require the Aurora lab mode setting to be ON. This feature substantially improves throughput for workloads with many transactions contending for rows on the same page. The improvement involves changing the lock release algorithm used by Aurora MySQL.	November 19, 2019

Aurora MySQL hash joins available without lab mode (p. 1771)	The hash join feature is now generally available for Aurora MySQL and does not require the Aurora lab mode setting to be ON. This feature can improve query performance when you need to join a large amount of data by using an equijoin. For more information about using this feature, see <a href="#">Working with hash joins in Aurora MySQL</a> .	November 19, 2019
Aurora MySQL 2.* support for more db.r5 instance classes (p. 1771)	Aurora MySQL clusters now support the instance types db.r5.8xlarge, db.r5.16xlarge, and db.r5.24xlarge. For more information about instance types for Aurora MySQL clusters, see <a href="#">Choosing the DB instance class</a> .	November 19, 2019
Aurora MySQL 2.* support for backtracking (p. 1771)	Aurora MySQL 2.* versions now offer a quick way to recover from user errors, such as dropping the wrong table or deleting the wrong row. Backtrack allows you to move your database to a prior point in time without needing to restore from a backup, and it completes within seconds, even for large databases. For details, see <a href="#">Backtracking an Aurora DB cluster</a> .	November 19, 2019
Billing tag support for Aurora (p. 1771)	You can now use tags to keep track of cost allocation for resources such as Aurora clusters, DB instances within Aurora clusters, I/O, backups, snapshots, and so on. You can see costs associated with each tag using AWS Cost Explorer. For more information about using tags with Aurora, see <a href="#">Tagging Amazon RDS resources</a> . For general information about tags and ways to use them for cost analysis, see <a href="#">Using cost allocation tags</a> and <a href="#">User-defined cost allocation tags</a> .	October 23, 2019
Data API for Aurora PostgreSQL (p. 1771)	Aurora PostgreSQL now supports using the Data API with Amazon Aurora Serverless v1 DB clusters. For more information, see <a href="#">Using the Data API for Aurora Serverless v1</a> .	September 23, 2019

Aurora PostgreSQL supports uploading database logs to CloudWatch logs (p. 1771)	You can configure your Aurora PostgreSQL DB cluster to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage. For more information, see <a href="#">Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs</a> .	August 9, 2019
Multi-master clusters for Aurora MySQL (p. 1771)	You can set up Aurora MySQL multi-master clusters. In these clusters, each DB instance has read/write capability. For more information, see <a href="#">Working with Aurora multi-master clusters</a> .	August 8, 2019
Aurora PostgreSQL supports Aurora Serverless v1 (p. 1771)	You can now use Amazon Aurora Serverless v1 with Aurora PostgreSQL. An Aurora Serverless DB cluster automatically starts up, shuts down, and scales up or down its compute capacity based on your application's needs. For more information, see <a href="#">Using Amazon Aurora Serverless v1</a> .	July 9, 2019
Cross-account cloning for Aurora MySQL (p. 1771)	You can now clone the cluster volume for an Aurora MySQL DB cluster between AWS accounts. You authorize the sharing through AWS Resource Access Manager (AWS RAM). The cloned cluster volume uses a copy-on-write mechanism, which only requires additional storage for new or changed data. For more information about cloning for Aurora, see <a href="#">Cloning databases in an Aurora DB cluster</a> .	July 2, 2019
Aurora PostgreSQL supports db.t3 DB instance classes (p. 1771)	You can now create Aurora PostgreSQL DB clusters that use the db.t3 DB instance classes. For more information, see <a href="#">DB instance class</a> .	June 20, 2019

<a href="#">Support for importing data from Amazon S3 for Aurora PostgreSQL (p. 1771)</a>	You can now import data from an Amazon S3 file into a table in an Aurora PostgreSQL DB cluster. For more information, see <a href="#">Importing Amazon S3 data into an Aurora PostgreSQL DB cluster</a> .	June 19, 2019
<a href="#">Aurora PostgreSQL now provides fast failover recovery with cluster cache management (p. 1771)</a>	Aurora PostgreSQL now provides cluster cache management to ensure fast recovery of the primary DB instance in the event of a failover. For more information, see <a href="#">Fast recovery after failover with cluster cache management</a> .	June 11, 2019
<a href="#">Data API for Aurora Serverless v1 generally available (p. 1771)</a>	You can access Aurora Serverless v1 clusters with web services-based applications using the Data API. For more information, see <a href="#">Using the Data API for Aurora Serverless v1</a> .	May 30, 2019
<a href="#">Aurora PostgreSQL supports database monitoring with database activity streams (p. 1771)</a>	Aurora PostgreSQL now includes database activity streams, which provide a near-real-time data stream of the database activity in your relational database. For more information, see <a href="#">Using database activity streams</a> .	May 30, 2019
<a href="#">Amazon Aurora recommendations (p. 1771)</a>	Amazon Aurora now provides automated recommendations for Aurora resources. For more information, see <a href="#">Using Amazon Aurora recommendations</a> .	May 22, 2019
<a href="#">Performance Insights support for Aurora global database (p. 1771)</a>	You can now use Performance Insights with Aurora Global Database. For information about Performance Insights for Aurora, see <a href="#">Using Amazon RDS performance insights</a> . For information about Aurora global databases, see <a href="#">Working with Aurora global database</a> .	May 13, 2019
<a href="#">Performance Insights is available for Aurora MySQL 5.7 (p. 1771)</a>	Amazon RDS Performance Insights is now available for Aurora MySQL 2.x versions, which are compatible with MySQL 5.7. For more information, see <a href="#">Using Amazon RDS performance insights</a> .	May 3, 2019

Aurora global databases available in more AWS Regions (p. 1771)	You can now create Aurora global databases in most AWS Regions where Aurora is available. For information about Aurora global databases, see <a href="#">Working with Amazon Aurora global databases</a> .	April 30, 2019
Minimum capacity of 1 for Aurora Serverless v1 (p. 1771)	The minimum capacity setting you can use for an Aurora Serverless v1 cluster is 1. Formerly, the minimum was 2. For information about specifying Aurora Serverless capacity values, see <a href="#">Setting the capacity of an Aurora Serverless v1 DB cluster</a> .	April 29, 2019
Aurora Serverless v1 timeout action (p. 1771)	You can now specify the action to take when an Aurora Serverless v1 capacity change times out. For more information, see <a href="#">Timeout action for capacity changes</a> .	April 29, 2019
Per-second billing (p. 1771)	Amazon RDS is now billed in 1-second increments in all AWS Regions except AWS GovCloud (US) for on-demand instances. For more information, see <a href="#">DB instance billing for Aurora</a> .	April 25, 2019
Sharing Aurora Serverless v1 snapshots across AWS Regions (p. 1771)	With Aurora Serverless v1, snapshots are always encrypted. If you encrypt the snapshot with your own AWS KMS key, you can now copy or share the snapshot across AWS Regions. For information about snapshots of Aurora Serverless v1 DB clusters, see <a href="#">Aurora Serverless v1 and snapshots</a> .	April 17, 2019
Restore MySQL 5.7 backups from Amazon S3 (p. 1771)	You can now create a backup of your MySQL version 5.7 database, store it on Amazon S3, and then restore the backup file onto a new Aurora MySQL DB cluster. For more information, see <a href="#">Migrating data from an external MySQL database to an Aurora MySQL DB cluster</a> .	April 17, 2019

<a href="#">Sharing Aurora Serverless v1 snapshots across regions (p. 1771)</a>	With Aurora Serverless v1, snapshots are always encrypted. If you encrypt the snapshot with your own AWS KMS key, you can now copy or share the snapshot across regions. For information about snapshots of Aurora Serverless v1 DB clusters, see <a href="#">Aurora Serverless and snapshots</a> .	April 16, 2019
<a href="#">Aurora proof-of-concept tutorial (p. 1771)</a>	You can learn how to perform a proof of concept to try your application and workload with Aurora. For the full tutorial, see <a href="#">Performing an Aurora proof of concept</a> .	April 16, 2019
<a href="#">Aurora Serverless v1 supports restoring from an Amazon S3 backup (p. 1771)</a>	You can now import backups from Amazon S3 to an Aurora Serverless cluster. For details about that procedure, see <a href="#">Migrating data from MySQL by using an Amazon S3 bucket</a> .	April 16, 2019
<a href="#">New modifiable parameters for Aurora Serverless v1 (p. 1771)</a>	You can now modify the following DB parameters for an Aurora Serverless v1 cluster: <code>innodb_file_format</code> , <code>innodb_file_per_table</code> , <code>innodb_large_prefix</code> , <code>innodb_lock_wait_timeout</code> , <code>innodb_monitor_disable</code> , <code>innodb_monitor_enable</code> , <code>innodb_monitor_reset</code> , <code>innodb_monitor_reset_all</code> , <code>innodb_print_all_deadlocks</code> , <code>log_warnings</code> , <code>net_read_timeout</code> , <code>net_retry_count</code> , <code>net_write_timeout</code> , <code>sql_mode</code> , and <code>tx_isolation</code> . For more information about configuration parameters for Aurora Serverless v1 clusters, see <a href="#">Aurora Serverless v1 and parameter groups</a> .	April 4, 2019
<a href="#">Aurora PostgreSQL supports db.r5 DB instance classes (p. 1771)</a>	You can now create Aurora PostgreSQL DB clusters that use the db.r5 DB instance classes. For more information, see <a href="#">DB instance class</a> .	April 4, 2019

Aurora PostgreSQL logical replication (p. 1771)	You can now use PostgreSQL logical replication to replicate parts of a database for an Aurora PostgreSQL DB cluster. For more information, see <a href="#">Using PostgreSQL logical replication</a> .	March 28, 2019
GTID support for Aurora MySQL 2.04 (p. 1771)	You can now use replication with the global transaction ID (GTID) feature of MySQL 5.7. This feature simplifies performing binary log (binlog) replication between Aurora MySQL and an external MySQL 5.7-compatible database. The replication can use the Aurora MySQL cluster as the source or the destination. This feature is available for Aurora MySQL 2.04 and higher. For more information about GTID-based replication and Aurora MySQL, see <a href="#">Using GTID-based replication for Aurora MySQL</a> .	March 25, 2019
Uploading Aurora Serverless v1 logs to Amazon CloudWatch (p. 1771)	You can now have Aurora upload database logs to CloudWatch for an Aurora Serverless v1 cluster. For more information, see <a href="#">Viewing Aurora Serverless DB clusters</a> . As part of this enhancement, you can now define values for instance-level parameters in a DB cluster parameter group, and those values apply to all DB instances in the cluster unless you override them in the DB parameter group. For more information, see <a href="#">Working with DB parameter groups and DB cluster parameter groups</a> .	February 25, 2019
Aurora MySQL supports db.t3 DB instance classes (p. 1771)	You can now create Aurora MySQL DB clusters that use the db.t3 DB instance classes. For more information, see <a href="#">DB instance class</a> .	February 25, 2019
Aurora MySQL supports db.r5 DB instance classes (p. 1771)	You can now create Aurora MySQL DB clusters that use the db.r5 DB instance classes. For more information, see <a href="#">DB instance class</a> .	February 25, 2019

<a href="#">Performance Insights counters for Aurora MySQL (p. 1771)</a>	You can now add performance counters to your Performance Insights charts for Aurora MySQL DB instances. For more information, see <a href="#">Performance Insights dashboard components</a> .	February 19, 2019
<a href="#">Amazon RDS Performance Insights supports viewing more SQL text for Aurora MySQL (p. 1771)</a>	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Aurora MySQL DB instances. For more information, see <a href="#">Viewing more SQL text in the Performance Insights dashboard</a> .	February 6, 2019
<a href="#">Amazon RDS Performance Insights supports viewing more SQL text for Aurora PostgreSQL (p. 1771)</a>	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Aurora PostgreSQL DB instances. For more information, see <a href="#">Viewing more SQL text in the Performance Insights dashboard</a> .	January 24, 2019
<a href="#">Aurora backup billing (p. 1771)</a>	You can use the Amazon CloudWatch metrics <code>TotalBackupStorageBilled</code> , <code>SnapshotStorageUsed</code> , and <code>BackupRetentionPeriodStorageUsed</code> to monitor the space usage of your Aurora backups. For more information about how to use CloudWatch metrics, see <a href="#">Overview of monitoring</a> . For more information about how to manage storage for backup data, see <a href="#">Understanding Aurora backup storage usage</a> .	January 3, 2019
<a href="#">Performance Insights counters (p. 1771)</a>	You can now add performance counters to your Performance Insights charts. For more information, see <a href="#">Performance Insights dashboard components</a> .	December 6, 2018
<a href="#">Aurora global database (p. 1771)</a>	You can now create Aurora global databases. An Aurora global database spans multiple AWS Regions, enabling low latency global reads and disaster recovery from region-wide outages. For more information, see <a href="#">Working with Amazon Aurora global database</a> .	November 28, 2018

<a href="#">Query plan management in Aurora PostgreSQL (p. 1771)</a>	Aurora PostgreSQL now provides query plan management that you can use to manage PostgreSQL query execution plans. For more information, see <a href="#">Managing query execution plans for Aurora PostgreSQL</a> .	November 20, 2018
<a href="#">Query editor for Aurora Serverless v1 (beta) (p. 1771)</a>	You can run SQL statements in the Amazon RDS console on Aurora Serverless v1 clusters. For more information, see <a href="#">Using the query editor for Aurora Serverless v1</a> .	November 20, 2018
<a href="#">Data API for Aurora Serverless v1 (beta) (p. 1771)</a>	You can access Aurora Serverless v1 clusters with web services-based applications using the Data API. For more information, see <a href="#">Using the Data API for Aurora Serverless</a> .	November 20, 2018
<a href="#">TLS support for Aurora Serverless v1 (p. 1771)</a>	Aurora Serverless v1 clusters support TLS/SSL encryption. For more information, see <a href="#">TLS/SSL for Aurora Serverless</a> .	November 19, 2018
<a href="#">Custom endpoints (p. 1771)</a>	You can now create endpoints that are associated with an arbitrary set of DB instances. This feature helps with load balancing and high availability for Aurora clusters where some DB instances have different capacity or configuration than others. You can use custom endpoints instead of connecting to a specific DB instance through its instance endpoint. For more information, see <a href="#">Amazon Aurora connection management</a> .	November 12, 2018
<a href="#">IAM authentication support in Aurora PostgreSQL (p. 1771)</a>	Aurora PostgreSQL now supports IAM authentication. For more information see <a href="#">IAM database authentication</a> .	November 8, 2018
<a href="#">Custom parameter groups for restore and point in time recovery (p. 1771)</a>	You can now specify a custom parameter group when you restore a snapshot or perform a point in time recovery operation. For more information, see <a href="#">Restoring from a DB cluster snapshot</a> and <a href="#">Restoring a DB cluster to a specified time</a> .	October 15, 2018

<a href="#">Deletion protection for Aurora DB clusters (p. 1771)</a>	When you enable deletion protection for a DB cluster, the database cannot be deleted by any user. For more information, see <a href="#">Deleting a DB cluster</a> .	September 26, 2018
<a href="#">Stop/Start feature Aurora (p. 1771)</a>	You can now stop or start an entire Aurora cluster with a single operation. For more information, see <a href="#">Stopping and starting an Aurora cluster</a> .	September 24, 2018
<a href="#">Parallel query feature for Aurora MySQL (p. 1771)</a>	Aurora MySQL now offers an option to parallelize I/O work for queries across the Aurora storage infrastructure. This feature speeds up data-intensive analytic queries, which are often the most time-consuming operations in a workload. For more information, see <a href="#">Working with parallel query for Aurora MySQL</a> .	September 20, 2018
<a href="#">New guide (p. 1771)</a>	This is the first release of the <i>Amazon Aurora User Guide</i> .	August 31, 2018

# AWS glossary

For the latest AWS terminology, see the [AWS glossary](#) in the *AWS General Reference*.
